Moreover, even if something such as this story of the historical origins of morality were true, it would not have important philosophical consequences. It would not establish the conclusion that human beings would never have developed morality if there had been no antecedent religion because a function of large parts of morality is to make possible human cooperation for mutual benefit. People would have encountered problems of cooperation even in the absence of religious beliefs and practices. Given human ingenuity, therefore, it is plausible to suppose that some form of moral belief and practice would have arisen in the course of human history, even if religion had never existed. Nor would history show that the truth of moral beliefs depends on the truth of religious beliefs. In general, it is fallacious to infer from the premise that one belief grew out of another that the truth of the former depends on the truth of the latter. Though modern chemistry grew out of alchemy, it is believed that modern chemistry is true, whereas alchemy is viewed as mostly false.

Morality would depend psychologically on religion if religious beliefs were causally necessary to motivate general compliance with the demands of the moral law. If

human beings are sufficiently selfish, many of them will not behave morally when the moral law requires large sacrifices from them—unless they believe that it is in the long run in their self-interest to do so. The common theistic belief that in the afterlife God rewards those who obey the moral law and punishes those who do not will thus serve to motivate compliance with the demands of moral duty. Maybe this purpose can only be effectively served by a belief that morality has the backing of a system of divine rewards and punishments in the afterlife. If this is the case, people who lack a religious belief of this kind will also lack what it takes to cause or motivate them to live up to the demands of morality when the going gets tough.

However, there are compelling reasons to think that the view of human nature on which this line of thought rests is inaccurate. Living in a social world in which many people lack belief in an afterlife, experience shows that many people are motivated to comply with the most stringent demands of morality even though they lack any belief in a system of divine postmortem rewards and punishments. It was clear to thoughtful people who inhabited social worlds—worlds in which belief in heaven and hell was nearly universal—that belief in divine punishment in the afterlife all too often did not suffice to motivate people who did believe to obey the moral law.

What is more, according to some moral theories, morality requires not only that people comply with the moral law but also that their compliance be motivated by respect for the moral law itself. For example, Kantians hold that actions that are in compliance with the moral law but are motivated by hope for rewards or fear of punishment have no moral worth, even though they are legally correct. In other words, morality demands both that people do their duty and that they do it for duty's sake. They will do the right thing for the wrong reason if their obedience to the moral law is caused by the belief that obedience will be rewarded or the belief that disobedience will be punished. On a view of this sort, religious belief in rewards and punishments in the afterlife constitutes a danger to morality; such belief may tempt people to rely on motivational factors that will deprive their actions of moral value, even when they are the actions prescribed by morality.

CONCEPTUAL DEPENDENCE

Some philosophers have maintained that concepts of moral deontology contain religious content. In a seminal paper defending a modified divine command account of

wrongness, Robert M. Adams (1987, 1999) proposed a theory in which being contrary to the commands of a loving God is part of the meaning of the term *wrong* in the discourse of some Jewish and Christian theists. And in her famous attack on modern moral philosophy, G. E. M. Anscombe (1981) recommended getting rid of the concepts of moral obligation and moral duty—and the concepts of moral right and wrong—because they belong to an earlier conception of ethics that no longer survives. The earlier conception she had in mind was a law conception. In it, according to Anscombe, the ordinary terms *should*, *needs*, *ought*, and *must* acquired a special sense by being equated in certain contexts with terms such as *is obliged*, *is bound*, or *is required*, in the sense in which one can be obliged or bound—or something be required—legally. She contends that “it is not possible to have such a conception unless you believe in God as a law-giver; like Jews, Stoics and Christians” (Anscombe 1981, p. 30). In the absence of this religious belief, the concepts of moral deontology have no reasonable sense; they are not really intelligible outside a divine law conception of ethics. Modern moral philosophers who lack belief in God would therefore do well to cease using the deontological concepts in their thinking.

Anscombe realizes, of course, that some nonreligious moral theorists will wish to retain a law conception of ethics without a divine legislator. In a Kantian conception of the moral law, for example, practical reason substitutes for God in the role of moral legislator. One's own practical reason engages in self-legislation; it is the authoritative source of moral obligations. Anscombe alleges that the idea of self-legislation is absurd. She remarks: “That legislation can be ‘for oneself’ I reject as absurd: whatever you do ‘for yourself’ may be admirable; but is not legislating” (Anscombe 1981, p. 37). However, she does not offer an argument to support the charge of absurdity. Hence Kantians are in a position to take issue with her cursory dismissal of the idea of moral self-legislation.

A deflationary approach to the deontological concepts provides another nonreligious alternative to the divine law conception. According to the account of this kind proposed by Williams (1983), obligations are not always prescriptively overriding; they do not always beat out ethical considerations of all other kinds. Instead, they are constituted by considerations to which some deliberative priority is granted in order to secure reliability in human social life. High deliberative priority is, in the case of some obligations, responsive to the basic and standing importance of the human interests they serve. Such obligations are negative telling people what not to do. In the

case of positive obligations, high deliberative priority is responsive to the demands imposed by emergencies. Williams thus indicates how it is possible for nonreligious moral theory to salvage at least deflated versions of the concepts of traditional moral deontology.

Anscombe's claim that the main concepts of traditional moral deontology have theistic content is intuitively plausible. However, moral belief and practice seem capable of surviving, almost unchanged, the replacement of such concepts by successors without religious content. And nonreligious moral theorists may even welcome the deflationary features of such a replacement if it is carried out along the lines envisaged by Williams.

EPISTEMOLOGICAL DEPENDENCE

Many religious believers hold that their moral convictions acquire some positive epistemic status, such as being justified or being warranted, and thereby count as moral knowledge, by virtue of being rooted in religious sources. Among the sources widely acknowledged in theistic religions are divine revelation recorded in sacred texts, divinely inspired prophetic utterances, and the teachers of divinely guided institutions. Frequently such sources purport to reveal divine commands by means of which God promulgates moral obligations. In addition, calls from God to perform particular actions or to enter into religious vocations are taken to be revealed in individual religious experience. Perhaps the most celebrated example in the history of Christianity comes from Augustine's *Confessions*. In retrospect, he took the childish voice he heard saying "Take and read" to be an indirect communication from God, because the biblical reading he did in response served providentially to trigger his conversion to Christianity. Because they hold that these sources are reliable—at least in certain circumstances—theists suppose that their deliverances, when properly interpreted, have positive epistemic status.

Religious diversity furnishes the grounds for an objection to this supposition. Survey the entire religious scene and it becomes evident that there is enormous disagreement among religious people about which sources are reliable, as well as how to interpret the deliverances of these various sources. Consequently, theists disagree among themselves about what God has commanded, and so they disagree about what is morally required or forbidden. Such disagreement undermines the claim that religious sources confer positive epistemic status on their deliverances. Positive epistemic status for one's moral convictions can only be derived from nonreligious sources, because only they can yield agreement. Jeremy

Bentham clearly articulated the epistemic asymmetry implicit in the objection. He remarked: "We may be perfectly sure, indeed, that whatever is right is conformable to the will of God: but so far is that from answering the purpose of showing us what is right, that it is necessary to know first whether a thing is right, in order to know from thence whether it be conformable to the will of God" (Bentham 1948, p. 22). In other words, people do not first come to know, from religious sources, that actions are commanded by God and then, on that basis, come to know that they are morally obligatory. Rather, they first come to know, from nonreligious sources, that actions are morally obligatory and then, on that basis, come to know that they are commanded by God.

Religious disagreement clearly does have a negative impact on the degree to which moral beliefs derive positive epistemic status from religious sources. At least for those who are sufficiently aware of it, religious diversity reduces that degree to a significant extent. After all, moral convictions would acquire a higher degree of positive epistemic status from religious sources if all the sources produced exactly the same outputs. However, nonreligious sources also yield conflicting moral judgments in pluralistic societies that tolerate free inquiry into moral issues. Anyone who is familiar with the history of secular moral theory in the modern era is apt to think it unlikely that agreement on a single moral theory will ever be achieved under conditions of free inquiry. So unless people are prepared to live with extensive moral skepticism, they should be reluctant to think that moral beliefs derive no positive epistemic status at all from religious sources merely because those sources yield conflicting deliverances.

Few people who live in religiously pluralistic societies rely exclusively on religious sources for epistemic support of their moral beliefs. Most people think the moral beliefs they form when responding intuitively to their experiences or to works of imaginative literature—or those beliefs acquired from interaction with parents and peers outside of religious contexts—often have positive epistemic status bestowed on them by nonreligious sources of these kinds. Even the religious people who inhabit such societies typically find themselves with moral convictions that stem from a plurality of sources, some religious and others nonreligious. However, unless the religious worldviews that serve to accredit their religious sources are disqualified for rational acceptance—which would be difficult to establish—religious people seem to be entitled to trust those religious sources and to regard them as conferring positive epistemic status on

their deliverances. Hence the moral convictions of religious believers apparently can, in principle, derive positive epistemic status from both religious and nonreligious sources. Bentham's view is therefore one-sided. While religious believers in pluralistic societies may acquire knowledge of what God commands by first coming to know their obligations, they may also acquire knowledge of their obligations by first coming to know what God commands. At least some of the moral convictions of such people can be epistemologically dependent on their religious beliefs and yet possess positive epistemic status. Or, at any rate, this view is more plausible than Bentham's if moral and religious skepticism is ruled out.

METAPHYSICAL DEPENDENCE

Beginning in the last third of the twentieth century, interesting ideas about how morality might depend metaphysically on God were developed and defended in the work of proponents of divine command theories of morality. In an influential paper offering suggestions to divine command theorists, William P. Alston (1990) proposed that axiology and deontology depend on God in different ways. In the axiological domain, in Alston's view, God is the paradigm or supreme standard of goodness. An analogy to the situation helps to clarify Alston's suggestion. He maintained that the meter could be defined in terms of a certain metal bar kept in Paris. What then made a particular table a meter in length was its conformity to a certain existing individual. Similarly, according to Alston, "what ultimately makes an act of love a good thing is not its conformity to some general principle but its conformity to, or approximation to, God, Who is both the ultimate source of the existence of things and the supreme standard by reference to which they are to be assessed" (Alston 1990, p. 320). There is, to be sure, a disanalogy as well. While it is arbitrary which particular physical object was chosen to be the standard meter, Alston does not suppose that it is similarly arbitrary whether God or someone else serves as the standard of goodness. Thus understood, moral axiology depends metaphysically on the nature and character of God. By contrast, within the domain of deontology, moral obligations and moral wrongness depend metaphysically on God's commands, and ultimately on the divine volitions expressed by those commands.

Alston's suggestions have been developed into a framework for ethics by Robert M. Adams. According to his theistic Platonism, God plays the role that the Form of the Good plays in Plato's metaphysics. God is the Good Itself, the standard of goodness; and other things are good

by virtue of resembling or being images of God in various ways. Modifying again his modified divine command theory of wrongness, Adams has claimed that wrongness bears the metaphysical relation of property-identity to contrariety to the commands of a loving God. He asserts: "My new divine command theory of the nature of ethical wrongness, then, is that ethical wrongness *is* (i.e., is identical with) the property of being contrary to the commands of a loving God" (Adams 1987, p. 139). And in presenting his framework for ethics, Adams sometimes says that an action's being obligatory consists in its being commanded by a loving God and that an action's being wrong consists in its being contrary to the commands of a loving God. The fundamental principle of obligation of a theory of this kind asserts that actions are obligatory if and only if, and solely because, they are commanded by a loving God. Its fundamental principle of wrongness claims that actions are wrong if and only if, and solely because, they are forbidden by a loving God. The metaphysical dependency of moral deontology on God is expressed in such principles by their requirement that actions are obligatory or wrong just because a loving God commands or prohibits them.

Of course, many philosophers have mounted objections to divine command theories of morality. Perhaps the most famous objection alleges that divine command theories render moral deontology arbitrary because God could have commanded absolutely anything. Thus, for example, God could have made cruelty for its own sake obligatory simply by commanding it. A defense against this allegation is available within the framework proposed by Alston and developed by Adams. God's nature and character, which constitute the standard of goodness, constrain what God can command. Though they may well leave some room for discretion in what God commands, God cannot command absolutely anything. If God is essentially loving and so could not be otherwise, it is impossible for God to command cruelty for its own sake. Hence, according to a divine command theory of this sort, it is likewise impossible for cruelty for its own sake to be obligatory.

Divine command theories have been defended against many other objections in work by Philip L. Quinn (1978) and Edward R. Wierenga (1989). As a result, it seems that these theories are good candidates for adoption by theists. If the larger theistic worldviews in which divine command theories are embedded are themselves rationally acceptable, an account of the metaphysics of morals, according to which morality depends on God, is a live option in moral theory.

CONFLICT THREATENED AND RESISTED

The arbitrariness objection to divine command theories suggests a threat that religion may—in some cases—pose to morality. It is the possibility of a religious obligation, imposed by divine command, coming into conflict with moral duties. The possibility is ominous because the historical record is full of crusades, inquisitions, and terrorist acts perpetrated in the name of theistic religions. Those who have done such things have often sincerely believed that they act in obedience to God's will. Within Jewish and Christian traditions, reflection on this possibility frequently focuses on the Hebrew Bible's story of the *akedah*, the binding of Isaac, narrated in Genesis 22. According to the story, God commands Abraham to offer his innocent son, Isaac, as a sacrifice, and Abraham shows that he is willing to perform this terrible deed of human sacrifice. As it turns out, an angel tells Abraham that he is permitted to substitute a ram for Isaac as the sacrificial victim, but the substitution is permitted precisely because Abraham has demonstrated to God his willingness not to withhold Isaac from being killed as a sacrifice.

Johannes de Silentio, the pseudonymous author of Søren Kierkegaard's *Fear and Trembling*, argues that the story of the *akedah* reveals a teleological suspension of the ethical. De Silentio conceives of the ethical in broadly Hegelian terms. People have *prima facie* duties to social groups of various size. If a duty to a smaller group conflicts with a duty to a larger group, the duty to the larger group is more stringent than—and hence overrides—the duty to the smaller group.

Thus, for example, Agamemnon's familial duty not to sacrifice his innocent daughter, Iphigenia, is overridden by his political duty to lead the Greek expedition to Troy. He is a tragic hero because he sacrifices Iphigenia. However, he remains within the ethical in doing so because he does so in order to fulfill his overriding political duty. Abraham is not a tragic hero. When he consents to sacrifice Isaac, he does not do so in order to fulfill some more stringent duty to a larger social group. Were he to carry out the sacrifice, he would be violating a duty that has not been overridden within the ethical. Yet Abraham lies under an absolute religious obligation to obey God. De Silentio regards Abraham's situation as a paradox that cannot be solved by mediation. He claims: "During the time before the result, either Abraham was a murderer every minute or we stand before a paradox that is higher than all mediations" (Kierkegaard 1983, p. 66). In other words, from the time he consents to sacrifice Isaac, Abraham is a murderer in his heart unless the ethical is sus-

pending from the outside in his case. But Abraham, whom de Silentio acknowledges to be the Father of Faith, is never a murderer. Therefore the divine command to Abraham must produce a suspension of the ethical.

Many theists do not wish to accept such a radical interpretation of the *akedah*. Kant is a notable example. In an often cited footnote in *The Conflict of the Faculties*, he insists: "Abraham should have replied to this supposedly divine voice: 'That I ought not to kill my good son is quite certain. But that you, this apparition, are God—of that I am not certain, and never can be, not even if this voice rings down to me from (visible) heaven'" (Kant 1996, p. 283). Kant's strategy of resistance to radical readings of the *akedah* carries with it an epistemological price. No matter how impressive the sound effects in the sky may be, they cannot confer on the claim that the voice commanding Abraham to kill Isaac actually came from God the exalted positive epistemic status of certainty. More generally, religious sources cannot confer epistemic certainty on claims about what God has commanded that conflict with epistemically certain moral judgments. On this Kantian view, therefore, there are limits on the extent to which claims about what God commands or wills can derive positive epistemic status from religious sources. No doubt this is a price many theists will be happy to pay in order to rule out certain sorts of conflict between their religious beliefs and the moral beliefs to which they are most deeply committed.

RELIGION AND POLITICS

Is it morally appropriate for citizens in a liberal democracy like the United States to support or oppose public policies solely for religious reasons? Although regularly serving as grist for the mill of political theorists, that question is not the familiar fare of ordinary political discussion. It's not a question about, or at least directly about, which laws our government ought to enforce. We're all too familiar with such questions—about the moral propriety and practical wisdom of abolishing the death penalty, legalizing abortion, declaring war on Afghanistan, and so on. Rather, it is a question about the kinds of *justifications* citizens should or should not have for their political commitments.

The most common position on this issue calls for a general constraint on the political use of religious reasons. Proponents of this constraint argue that citizens must support public policies for secular reasons and therefore that they morally ought to restrain themselves from supporting public policies solely for religious reasons. So, for example, they argue that a citizen who lacks any secular reason to criminalize abortion or discourage homosexuality ought to refrain from supporting any such policy.

This entry presents the main lines of argument for and against this view that citizens should obey the *doctrine of restraint*: that they ought to restrain themselves from supporting or opposing public policies solely for religious reasons.

LIBERAL DEMOCRACY, RELIGIOUS PLURALISM, AND THE DOCTRINE OF RESTRAINT

In order to understand why a given philosophical commitment is significant, it's helpful to identify the problem that that commitment is supposed to solve. This is true of the doctrine of restraint: It is significant because it claims to solve a problem that naturally arises from the institutionalization of a liberal democracy's deepest normative commitments. What is that problem?

At the very least, a liberal democracy is a form of government that affirms and protects a citizen's rights—to private property, to freedom of association, to freedom

of conscience, and so on. The most fundamental of these rights, both morally and historically, is the right to religious freedom: Citizens are entitled to decide which religious creed or practice, if any, they wish to pursue. So a liberal democracy just is a kind of political system that provides citizens with considerable leeway to decide for themselves what they are to believe regarding religious matters.

Protection of the right to religious freedom has far-reaching social consequences, the most important of which is religious pluralism: A society that assiduously protects each citizen's right to religious freedom will find its citizens disagreeing among themselves as to which religion is true, how to please God, and so on. What explains this close connection between religious freedom and religious pluralism? Because our rational capacities are not powerful enough to produce widely convincing proofs (or refutations) of religious truth claims, even the flawless employment of our rational capacities will lead to disagreements about such matters. From this claim about the limited powers of our rational capacities, it follows that citizens who are free to decide which religious tradition to affirm will embrace a diversity of religious traditions. So, then, since well-functioning liberal democracies effectively protect the right to religious freedom, and since the effective protection of religious freedom results in a citizenry that is rationally committed to divergent religious traditions, it follows that well-functioning liberal democracies will be characterized by a citizenry that is rationally committed to divergent religious traditions.

This fact of religious pluralism raises a question of enormous moral and practical import: How are the multifariously committed citizens of a liberal democracy to make collective decisions about the laws with which each citizen must comply? For advocates of the doctrine of restraint, the pervasive pluralism of a liberal democracy renders obedience to the doctrine of restraint imperative: The morally appropriate response of citizens to religious pluralism is to refrain from resolving public matters solely for sectarian, and therefore for religious, reasons.

THE DOCTRINE OF RESTRAINT

Although agreed on a core prohibition of exclusively religious support for public policies, advocates of the doctrine of restraint diverge in their formulations of this doctrine. Some have argued that it constrains all political actors, including citizens, legislators, judges, and other public officials; others limit its scope to public officials. Some have argued that the doctrine enjoins restraint with respect to all public policies, whereas others have limited

its scope to coercive public policies; others further delimit its scope to laws of fundamental and structural importance. Some have argued that the doctrine of restraint applies only to public political advocacy, whereas others contend that it should also apply to political decision-making the decision as to whether to vote for some candidate, for example.

A more important variation is between the inclusive formulation of the doctrine of restraint on which this entry focuses and a more demanding but less plausible cousin with which the inclusive version is sometimes confused. The inclusive version of the doctrine of restraint has been most effectively advocated by Robert Audi (2000), who insists that citizens should *include* secular arguments in their political practice, not that they should *exclude* religious reasons. According to Audi, citizens may support only those public policies for which they have secular reasons they regard as sufficiently weighty that they would continue to support the relevant policies absent corroborating religious reasons. But as long as citizens have, and are motivated by, adequate secular reasons for a given public policy, they are free to appeal to religious reasons as well. So inclusivists such as Audi advocate a kind of *limited* privatization: Citizens are free to rely on religious reasons for public policies so long as they have correlative secular reasons but must refrain from supporting public policies for which they have only religious reasons

Other advocates of the doctrine of restraint have demanded a complete privatization of religious reasons. This *exclusive* version of the doctrine of restraint, advocated by Richard Rorty (1994), demands that citizens refrain entirely from relying on religious reasons when supporting or opposing public policies. Its advocates expect that the real business of politics will be conducted exclusively on the basis of secular argument. But this complete privatization of religious reasons is gratuitously exclusionary: There is no good reason to stigmatize citizens who support a given public policy on religious grounds if those citizens also have and are sufficiently motivated by plausible secular reasons. Any serious evaluation of the doctrine of restraint, therefore, will pay due regard to the more moderate, inclusive version articulated by Audi.

AGAINST THE DOCTRINE OF RESTRAINT

Critics of the doctrine of restraint reject even its inclusive formulation. According to Eberle, (2002), Perry (2003), and Audi and Wolterstorff (1997), citizens need not be

morally criticizable in any respect for supporting public policies for religious reasons—even solely for religious reasons. These critics of the doctrine of restraint need not and do not typically license an “anything goes” approach. They may advocate *substantive* constraints on the reasons citizens have for their favored public policies—for example, they might argue that citizens ought not appeal to reasons that deny the dignity of their fellow citizens. They may also advocate *epistemic* constraints on the manner in which citizens support public policies, arguing, for example, that citizens should engage in critical reflection on their reasons. They may even argue that citizens should *try* to articulate secular reasons for their favored political commitments: Citizens ought to do what’s within their power to speak to their fellow citizens in ways that their fellow citizens can take seriously and so ought to do what’s in their power to articulate reasons that speak to their secular compatriots—presumably these will be secular reasons. Critics of the doctrine of restraint argue, however, that none of these constraints provide an adequate basis for a general constraint on religious reasons; so long as a citizen satisfies the appropriate substantive and epistemic constraints, and so long as he or she genuinely searches for a plausible secular rationale, then a citizen has no good reason not to support a given public policy solely for religious reasons.

These critics argue that advocates of restraint must discharge a heavy burden of proof: Absent sufficiently powerful reasons in favor of the doctrine of restraint, citizens may refuse without compunction to comply with that doctrine. The argument for this distribution of the burden of proof is short, direct, and powerful. We surely want and expect citizens to treat their compatriots as conscience dictates: A citizen ought to support or oppose public policies on the basis of what he or she sincerely and responsibly believes to be the just and decent thing to do. And sometimes what a citizen sincerely takes to be the just and decent thing to do will depend solely on religious beliefs. And in that case, the heavy presumption in favor of acting in accord with conscience translates into a heavy presumption permitting a citizen to decide, solely on religious grounds, to support or oppose some public policy. Consider, for example, a Christian pacifist who, after sober and competent reflection on the morality of war, concludes that the life and teachings Jesus Christ forbid the lethal use of force. In this case, our conviction that citizens should support those public policies that they actually believe to be morally correct should lead us to expect—indeed, encourage—Christian pacifists to oppose war, even though they have an exclusively religious rationale for that policy.

So critics of the doctrine of restraint will appeal to the very great good of a citizen’s acting in accord with her conscience to establish a heavy presumption in favor of the moral propriety of that citizen’s making political decisions solely on religious grounds. But that there is a presumption against the doctrine of restraint by no means implies that that doctrine is false. After all, presumptions can be overridden, and the burden of proof can be met—so long as advocates of the doctrine of restraint can marshal sufficiently powerful arguments.

THE ARGUMENT FROM RESPECT

Some advocates of the doctrine of restraint have argued that citizens should obey the doctrine of restraint out of respect for their compatriots. When a citizen supports a public policy, she is complicit in authorizing the government to coerce citizens. But her compatriots aren’t mere playthings who may be forced to satisfy her whims; rather, they’re rational persons who are fully capable and desirous of deciding for themselves how they will live their lives on the basis of reasons *they* find acceptable. And so if she is to respect her compatriots as persons, she must be committed to providing them with reasons that they find, or at least can find, acceptable. That requires a search for some common ground, premises that one might *share* with one’s compatriots. Given the pervasive religious pluralism of a well-functioning democracy, this common ground will most likely be secular, not religious in content. On this view, advocated by Charles Larmore (1987), it is respect for the dignity and autonomy of our fellow citizens that requires us to abide by the doctrine of restraint.

The argument from respect is both popular and controversial. Critics have expressed doubt that reliance on religious reasons—even exclusive reliance—necessarily involves disrespect for other persons. Some argue that it is unclear why any disrespect can be imputed to citizens who affirm their compatriots’ dignity, who are willing to engage in critical analysis of their favored public policies, and who provide their fellow citizens with sincerely held and carefully elaborated reasons that are, nevertheless, based on religious doctrines. Consider again the Christian pacifist: There is every reason to believe that her opposition to war is based on the kind of moral commitment that putatively underlies the doctrine of restraint: respect for *all* other persons. The argument from respect seems an entirely unpromising rationale for requiring a Christian Pacifist to exercise restraint—thereby casting doubt on the doctrine of restraint insofar as it constrains on religious reasons generally.

THE ARGUMENT FROM RELIGIOUS WARFARE

Religious wars have played a defining role in the history of liberal democracies; the commitment to religious freedom was formulated and defended in reaction to a century and a half of wars fought to “resolve” religious disagreements. The specter of religious warfare lingers on, and in some cases, that wariness motivates the argument from religious warfare.

Here is one way to formulate that argument. Religious wars are morally abhorrent: Military conflicts guided by religious aims are purely destructive, extraordinarily vicious, and utterly without redeeming value. If large numbers of citizens rely solely on religious reasons to direct state coercion, there is a glaring temptation to enlist the power of the state to force conversion and persecute heretics, thereby provoking armed conflict; hence only a policy of religious restraint can ward off the specter of sectarian bloodshed. In short, that citizens firmly commit to supporting only those public policies for which they have an adequate secular rationale is a crucial bulwark protecting us from confessional conflict.

It is, however, reasonable to deny that there is a *realistic* prospect that segments of the population of the United States will enter into armed conflict over religious matters. Religious warfare is not a realistic prospect in the contemporary United States because we have learned how to prevent it and have taken the appropriate measures: The proper preventive for religiously generated strife is constitutional and cultural, viz., effective protection of religious freedom on the part of the government and commitment to religious freedom on the part of citizens. This point has direct implications for the idea that obedience to the doctrine of restraint is necessary to prevent religious war. For it implies that what’s essential in preventing religious war is that citizens are fully committed to religious freedom, not that they refrain from making use of that right to support public policies solely for religious reasons. So long as citizens are firmly committed to religious freedom, their willingness to support public policies solely for religious reasons has no realistic prospect of engendering religious warfare.

THE ARGUMENT FROM PUBLIC DISCOURSE

A third argument for the doctrine of restraint, advocated by Daniel Conkle (1993–1994) hinges on the following two claims: (1) that healthy public discussion of public policies is a great moral and political good and (2) that

that good would be threatened by the refusal of large numbers of citizens to abide by the doctrine of restraint. On this view citizens should not support public policies without reflecting on those policies with their compatriots; as an implicit acknowledgment of human fallibility, the pursuit of such political discourse invites our compatriots to challenge our mistaken assumptions and inherited prejudices. Moreover, a commitment to public discourse about public policies affords those who hold a minority view the opportunity to convince other citizens of good will that their minority position is in fact correct. Hence this kind of public discourse is advanced as an important moral good.

In order to secure that good, citizens must abide by a number of constraints, especially that which requires citizens to support public policies on the basis of reasons open to rational evaluation and debate. Religious reasons, by contrast, are not subject to rational analysis and thus require a nonrational, subjective act of faith that can only be experienced, not rationally analyzed or debated. On this view compliance with the doctrine of restraint is a prerequisite for healthy discourse about public policies.

Critics have pointed to a number of problems in the argument from public discourse. Insofar as advocates of the doctrine of restraint depend heavily on the argument from public discourse, they seem to rely on controversial claims about the epistemic status of religious reasons. If religious reasons are not amenable to rational criticism by others, then it follows that religious reasons lack what many regard as an important epistemic desideratum. But this demotion of the epistemic status of religious reasons likely to trouble religious citizens. As this entry noted at the outset, the primary significance of the doctrine of restraint is that it putatively provides a morally attractive guideline for a pluralistically committed citizenry to follow when supporting public policies. This implies that the doctrine of restraint should be acceptable not just to secular citizens, but to all citizens and therefore to the religious citizens who are expected to comply with that doctrine. But many religious believers are likely to regard the epistemic assessment of religious claims that underpins the argument from public discourse as thoroughly objectionable; after all, it’s dubious that we should place our trust in claims, whatever their content, that aren’t amenable to rational criticism by others. So the argument from public discourse recommends that religious believers exercise restraint, but on grounds that many religious believers will find deeply objectionable. It seems likely, then, that the best argument advocates of the doctrine of restraint can muster will be anathema to the very citizens

who are expected to comply with that doctrine, thus emptying the doctrine of restraint of its primary significance.

CONCLUSION

The literature on the proper role of religious reasons in liberal politics is voluminous. And so as one might expect, the preceding discussion is far from definitive (or exhaustive for that matter). But this should hardly be surprising: The problem to which the doctrine of restraint responds rests on a pluralistic social reality that results from the successful implementation of a liberal democracy's defining commitments. That social reality is here to stay, as are the problems that it engenders, and so reflective people will continue to advocate for and criticize proposed solutions to those problems. The doctrine of restraint, and its critics, will be with us for the foreseeable future

RELIGION AND THE BIOLOGICAL SCIENCES

HISTORY

Plato and Aristotle recognized that understanding nature demands reference to factors—what Aristotle called "final causes"—that in some sense anticipate what will or should happen. In the *Timaeus*, Plato wrote, "From the combination of sinew, skin, and bone, in the structure of the finger, there arises a triple compound, which, when dried up, takes the form of one hard skin partaking of all three natures, and was fabricated by these second causes, but designed by mind, which is the principle cause with an eye to the future." He continued, "For our creators well knew ... that many animals would require the use of nails for many purposes; wherefore they fashioned in men at their first creation the rudiments of nails. For this purpose and for these reasons they caused skin, hair, and nails to grow at the extremities of the limbs" (*Timaeus*, 76d–e).

Such adaptations, organic features that demand a final-cause understanding, are the basis for (what was to prove) a very popular and longstanding proof of God's existence. The forward-looking aspect of adaptations comes from the fact that they seem as if they were designed. They are like artifacts. Why? Quite simply because adaptations are artifacts—the artifacts of a deity. Just as a couch has a couch designer, so the hand and the eye must have a hand and eye designer. There is no necessary implication that there is just one designer, or that it has the attributes of the Judeo-Christian God—eternal, all powerful, all loving, creator of all from nothing—but this Greek argument (known as the "argument from design") was taken over by the great Christian philosophers and theologians, and became one of the main supports of the route to God through reason (natural theology).

This argument continued to enjoy great popularity and force right into the nineteenth century. Archdeacon William Paley in his book *Natural Theology* (1802) pro-

moted the argument: The eye is like a telescope; telescopes have telescope makers; therefore eyes must have eye makers—what one might call the Great Optician in the sky. By this time, however, the pendulum was starting to swing the other way, with biology giving theists cause for concern. The eighteenth century saw the rise of evolutionary speculations—hypotheses that organisms are the end results of long, slow, natural processes of development from very different and much simpler forms. At the most obvious level, evolutionary ideas challenge the Genesis story of creation. But though this was certainly a stumbling block for many, believers have long had resources to deal with problems caused by literal interpretations of the Bible.

Far more threatening to the theist was the connection between organic evolution and the doctrine of intellectual or cultural progress. As humans supposedly have risen up from ignorance and poverty in the cultural world to the sophisticated state in which we humans now find ourselves, so in the world of organisms, primitive forms have developed into humans. Cultural development points to biological evolution, which in turn reinforces cultural development. To quote an early evolutionist, Erasmus Darwin (a grandfather of Charles):

Imperious man, who rules the bestial crowd,
Of language, reason, and reflection proud,
With brow erect who scorns this earthy sod,
And styles himself the image of his God;
Arose from rudiments of form and sense,
An embryon point, or microscopic ens!
(1803, 1, 295–314)

All of this progressivism was a direct challenge to the Christian notion of Providence. For the believer, because of Adam's sin, we are in a fallen state. To earn us salvation in this fallen state, God intervened in his creation, choosing freely to die on the cross. This means that our happiness comes not from our merits, but simply as the result of God's forgiveness and grace. Progress challenges this. It carries the central message that improvement is possible and due entirely to human intentions and labors. Success comes from our own efforts, not from those of others—including God. As part of the picture of progress, evolution was rightly seen as challenging conventional religious verities.

Although popular in some quarters, evolution was always somewhat of a pseudoscience. As Immanuel Kant pointed out in his third critique, *The Critique of Judgment*, there are difficulties with final causes. Such a complex, apparently intentional entity as the eye simply could have come about through blind law. Charles Darwin

addressed this issue in *On the Origin of Species*, published in 1859. Committed to evolution, Darwin sought a cause that would speak to adaptation. This he found in the mechanism of natural selection. More organisms are born than can survive and reproduce. This brings on a struggle for existence. Organisms tend to vary naturally, and the winners in the struggle (the fit) have features not possessed by the losers (the unfit). Moreover, these features tend to be deciding factors in whether an organism is successful or unsuccessful. Hence, equivalent to the selection practiced by animal and plant breeders, there is a natural selection, where the winners pass on their favorable features. Over time this leads to full-blown evolution, a key feature of which is the development and perfection of adaptations.

Although he himself was never an atheist—at the time of writing the *On the Origin of Species* he was a deist and later turned to agnosticism—Darwin apparently drove a stake through the heart of the argument from design. The eye resulted from blind, unguided processes through natural selection. There is no need to invoke a designer. In the words of the contemporary English biologist Richard Dawkins (1986), only after Darwin was it possible to be “an intellectually fulfilled atheist.” As expected, not everyone agrees that such a conclusion follows. Below are the different positions taken on the relation of biology and religion in the post-Darwinian era.

SEPARATION

One strategy is to separate science and religion, specifically, biology and Christianity. This means that biology cannot support religion, but then again neither can it refute it. A common suggestion is that biology can tell us how things occur—that humans came from apelike creatures, for example—but it cannot tell us why things occur—why there should be creatures with the conscious ability to tell good from evil. The great English theologian John Henry Newman, an Anglican convert to Catholicism, had no trouble at all with evolution. It was simply not something that bore on his faith. “I believe in design because I believe in God; not in a God because I see design.” He continued, “Design teaches me power, skill and goodness—not sanctity, not mercy, not a future judgment, which three are of the essence of religion” (Newman 1973, 97).

This kind of reversal of the argument—design because of God, rather than God because of design—found much favor in the twentieth century, particularly in circles influenced by Karl Barth, another major critic of natural theology. In the opinion of such thinkers, often

labeled “neo-orthodox,” evolution is true. But this does not prove anything affecting religion. In the language of the German theologian Wolfhart Pannenberg (1993), we must strive for a “theology of nature,” where the beauties of the living world enrich our faith, rather than a “natural theology,” where the living world is used as a substitute for faith. Thus, Dawkins is wrong not so much in thinking that one can be an intellectually fulfilled atheist, but in thinking that this is the end of the journey. It is the beginning. Darwin shows that there can be no proofs, and that is where faith begins.

INTERACTION

Not every post-Darwinian thinker has been so negative about natural theology. Many think that Darwin’s work is the spur to find a new natural theology, a natural theology that accepts evolution and works with it rather than against it. Instead of rejecting progress, Christians should take it on board in some fashion, arguing that we humans should work with God to achieve our salvation. The rise of organisms, from slime to humans, “from monad to man,” as it was traditionally put, is proof that not all is random and without purpose. It shows that God is working out his plan, and also that we are obligated to work with him.

The thinker who tried most fully to work out a theology that stayed true to conventional Christian belief and yet made the upward progressive message of evolutionism central was the French Jesuit and paleontologist Pierre Teilhard de Chardin. In his masterwork *The Phenomenon of Man*, Teilhard saw life evolving upward through the realm of life (the biosphere), to the realm of humans and consciousness (the noosphere), and then even further onward and upward to the Omega Point, which in some way he identified with the Godhead, with Jesus Christ. “An ever-ascending curve, the points of transformation of which are never repeated; a constantly rising tide below the rhythmic tides of the ages—it is on this essential curve, it is in relation to this advancing level of the waters, that the phenomenon of life, as I see things, must be situated” (p. 101).

One major problem with this whole approach is less whether the post-Darwinian Christian should accept the doctrine of progress than whether the post-Darwinian evolutionist should accept such a doctrine. If natural selection is true, then change is much relativized. Which species are fit? Not necessarily those at the top of an absolute scale. Intelligence might seem a good thing, but it has major costs, not the least of which is a constant supply of quality protein. In many circumstances, stupidity

and strength might be a better biological strategy. Many evolutionists now reject progress entirely. The late Stephan Jay Gould (1989), paleontologist and science writer, argued that there is no genuine progress, and certainly no guarantee that if the tape of life were replayed, humans would inevitably emerge.

This is not the last word. Darwin himself believed in progress and thought that natural selection gives rise to what biologists of 2005 label “arms races,” where one line of organisms competes and improves adaptations against the threat of other lines. Intelligence is an end result. Darwin has his supporters in the early twenty-first century, notably the English paleontologist Simon Conway Morris (2003), who argues that selection leads steadily to the conquering of one major ecological niche after another. Consciousness is the prize at the top, waiting to be grasped, and if not by humans, then by some other contender with outstretched paw.

DARWINIAN OPPOSITION TO THEISM

Dawkins is an atheist. He thinks that Darwinian evolution is hardly neutral. Although the argument from evil—that the bad things of this world are incompatible with an all-loving, all-powerful god—is not new with Darwin, his theory focuses on evil and makes it a central part of the evolutionary story. For Dawkins and others, this is confirmation that the Christian God does not exist, that other forms of deity are not worth entertaining, and hence that life has no meaning, that it just is. “In a universe of blind physical forces and genetic replication, some people are going to get hurt, other people are going to get lucky, and you won’t find any rhyme or reason in it, nor any justice. The universe we observe has precisely the properties we should expect if there is, at bottom, no design, no purpose, no evil and no good, nothing but blind, pitiless indifference” (Dawkins 1995, 133).

Theists have standard counters to the problem of evil (Ruse 2001). Some theists separate moral evil (the extermination of Jews at Auschwitz) from physical evil (cancer). In the case of moral evil, it is better that humans have free will, even though they will do wrong, these theists argue, than that humans have no genuine choices at all. This may or may not be an adequate response, but if one argues for the philosophical position known as compatibilism—the position that freedom and natural law are not contradictory—then an evolutionist could in principle support this defense. The fact that we humans are the product of biological law and still subject to it does not in itself deny some dimension of freedom and ability to act on our own choices.

In the case of physical evil, recourse is often made to an argument of Gottfried Wilhelm Leibniz (1646–1716), namely that such evil is an unfortunate but unpreventable consequence of a world governed by natural law. Here too the evolutionist has a defense. Somewhat paradoxically, Dawkins himself supports this counter, for he argues that if organisms were created naturally, then adaptive complexity could have been achieved only through the action of natural selection. “The Darwinian Law ... may be as universal as the great laws of physics” (Dawkins 1983, 423). One might still argue that given the consequent pain, it was a pity that God created at all, but this is a different claim totally independent of evolution. From the viewpoint of biology, if God did create and did so through natural law—and there may be good theological reasons for this—then Darwinism does not refute this, but shows rather why physical pain is bound to occur.

INTELLIGENT DESIGN

Notoriously, from the beginning many American evangelical Christians have rejected all forms of evolution. The best-known clash between such Christians and evolutionists occurred in 1925 in the state of Tennessee, when the young school teacher John Thomas Scopes was put on trial for teaching evolution. As it happened, although Scopes was found guilty, his penalty was overturned on appeal, and that was the end of so-called creationism for several decades. Yet thanks to a number of dedicated fundamentalists, people who insist on taking every verse of the Bible literally, opposition to evolutionism started to grow again, particularly after the publication in 1961 of *Genesis Flood*, a work by the biblical scholar John Whitcomb and the hydraulic engineer Henry Morris defending every verse of the Bible. This led to renewed efforts to get literal biblical teachings into publicly financed American schools, and again the matter ended in court, this time in Arkansas in 1981, where it was ruled that “creation science” is religion and as such has no place in school biology classes.

More recently, those who oppose Darwinian evolution on religious grounds have been promoting a more sophisticated form of creationism. Supporters of intelligent design argue that the organic world is just too complex and tightly functioning to have been produced by natural forces. The world, particularly at the micro level, exhibits what they call “irreducible complexity,” and hence cannot possibly have been the result of something like natural selection. In the words of Michael Behe, author of *Darwin’s Black Box*, an “irreducibly complex

biological system, if there is such a thing, would be a powerful challenge to Darwinian evolution. Since natural selection can only choose systems that are already working, then if a biological system cannot be produced gradually it would have to arise as an integrated unit, in one fell swoop, for natural selection to have anything to act on” (p. 39).

As an example of something irreducibly complex, Behe turns to the micro world of the cell and of the mechanisms found at that level. Take bacteria that use flagella, driven by a kind of rotary motor, to move around. Every part is incredibly complex, and so are the various parts in combination. For example, the flagellin (the external filament of the flagellum) is a single protein that forms a kind of paddle surface contacting the liquid during swimming. Near the surface of the cell, one finds a thickening, just as needed, so that the filament can be connected to the rotor drive. The connector is a hook protein. There is no motor in the filament, so it has to be located somewhere else. And so on. Such an intricate mechanism is much too complex to have come into being in a gradual fashion. Only a one-step process will do, and this one-step process must involve some sort of designing cause. Behe and his supporters, including the mathematician-philosopher William Dembski, are careful not to identify this designer with the Christian God, but the implication is that the designing cause is a force beyond the normal course of nature. Biology works through “the guidance of an intelligent agent” (p. 96).

Evolutionists strongly deny that there are irreducibly complex phenomena, and they strive to show that the adaptations highlighted by intelligent-design theorists could in fact have been produced by natural selection. Of course, often mechanisms as we see them today could not function if a part were removed, but this is compatible with their coming into being through blind natural law. Perhaps formerly essential but now redundant parts have been removed. Think of a stone arch. Build it without supports, and the center keystones will fall before they are secured. Build supports and then build the arch, and the completed structure will stand even after the supports are removed.

In any case, argue critics of intelligent-design theory, there are significant theological problems with the theory, which is little more than Paley’s natural theology brought up to date with some modern examples. If an intelligence intervened to produce the irreducibly complex, why does the intelligence not intervene to prevent life’s simple but devastating occurrences? Sometimes a simple change in the structure of DNA can have horrific effects on an indi-

vidual. Why are these sorts of occurrences not prevented? One might say that the intelligence is not interested in doing everything, but if this is true, then it at least seems that the intelligence pointed to by intelligent-design theory is far removed from the traditional Christian conception of God.

CONCLUSION

There is more debate at the beginning of the twenty-first century than perhaps at any other time about the relationship between science and religion, and in particular between biology and Christianity. It is neither static nor philosophically uninteresting.

RELIGION AND THE PHYSICAL SCIENCES

This entry is concerned with philosophical questions arising from the interaction of religion and physical science. Here the focus is primarily upon Western religious monotheism, for this is the larger religious context in which modern science arose. And among the physical sciences, the focus is on astronomy and physics.

HISTORICAL ROOTS

The relationships between physical science and monotheism have deep roots in the history of Western thought. The simple assumption that religion and science have been and remain in conflict is falsified by the historical data. Rather, more complex and interesting connections hold between religious faith and scientific understanding in at least three domains: individual scientists and scholars, social institutions, and worldviews. At the individual level, the facts are too complex for one simple view to be true all the time, or even in a majority of cases. At the institutional level, the record of religion is at best one of indifference, and at worst outright opposition to physical science. At the level of worldviews, in contrast, Western religion has helped to make modern physical science possible.

The regular pattern of astronomical events traced by ancient Babylonian astrologers and the understanding of the physical world in Greek natural philosophy and astronomy gave currency to the idea that there must be a supreme god of some sort behind the universal patterns of causes and motions in heaven and earth. As Plato argued in *The Laws*, "If the whole path and movement of heaven and all its contents are of like nature with the motion, revolution, and calculations of wisdom, and proceed after that kind, plainly we must say that it is the supremely good soul that takes forethought for the universe and guides it along that path" (bk. 10, 897c). Both Plato and Aristotle were philosophical monotheists, a view based in part on their understanding of the workings of nature.

The tradition of Greek natural philosophy continued to develop in the monotheistic traditions of Christian, Jewish, and Arabic scholarship by means of commentaries on the physical works of Aristotle. What these philosophers had in common was what we might call a *macrodesign* scientific worldview: God created the whole cosmos and sustains the principles and laws of nature that regulate physical interaction and motion. The purpose of natural philosophy (as physical science was then

called) was to investigate the primary and secondary causes sustained by the first cause. Natural philosophy did not discuss God per se as the first cause, nor did it appeal to God as an explanation for the natural phenomena of the world. God's nature was the province of theology. This division of labor aided the development of the rationality of early modern science in the European universities in the thirteenth century, the later Middle Ages, and the Renaissance.

Important to this development was the influx of the "new" Aristotelian science from Arabic sources. Combined with a Platonic-Pythagorean tradition of mathematics, this Aristotelian tradition of empirical study was assisted by voluntarism in theology and nominalism in metaphysics. This complex tradition of inquiry formed the background to the development of early modern science and made sense of a quest for empirical, mathematical laws of nature grounded in the will of the Creator. A good historical example of this combination is Jean Buridan (c. 1292–1358), a natural philosopher and one of the most honored intellectuals in Europe, who was twice elected rector of the University of Paris. In his commentary on Aristotle's *On the Heavens*, he wrote, "In natural philosophy we ought to accept actions and dependencies as if they always proceed in a natural way" (bk. 2, ques. 9; p. 423 f.). In the same question, Buridan went on to attribute the existence and design of the universe to God as first cause, but he did not appeal to God in natural philosophy.

The scientific revolution was a genuine revolution in human thought. Despite some continuity with the Middle Ages, a whole new way of seeing the world was born. The contributions of Nicolaus Copernicus, Galileo Galilei, Johannes Kepler, and Isaac Newton, for example, gave rise to a new understanding of the physical cosmos. While a macrodesign worldview did assist in the development of early modern science, there was tension at the institutional level. The Catholic Church continued to insist upon its right to judge theological truth, including the proper way to interpret the Scriptures. The Catholic astronomer Galileo Galilei (1564–1642) ran into trouble with the Congregation of the Holy Office (the Inquisition) over exactly this point. In his famous "Letter to the Grand Duchess Christina" (1615/1957), he argued as an individual scholar that the Scriptures should be interpreted in a manner consistent with the new Copernican astronomy. The Counter-Reformation authorities in Rome soon banned the work of Copernicus "until corrected," and got Galileo to agree not to publish his views except as purely hypothetical theories. When Galileo

broke this agreement by publishing his *Dialogue concerning the Two Chief World Systems*, he was suspected of heresy and forced to recant publicly. This became the most famous example of institutional religion suppressing the scientific quest for truth in the physical sciences.

For the most part the Christian churches have been unconcerned with science, focusing instead on spiritual truth and religious practices. Indeed, by creating the Western university and the hospital, the Church provided indirect support for scientific research.

METHODOLOGY

By way of contemporary issues of philosophical interest, the rise in the latter half of the twentieth century of theology-and-science debates has stimulated a number of methodological questions concerning both religion and science. The question of how we know in both disciplines has given rise to philosophical investigation into the nature and limits of knowledge in physical science and academic theology. Thomas Kuhn's *Structure of Scientific Revolutions* (1962), a revolutionary work in the philosophy of science, made a lasting contribution to the dialogue between theology and science. Science, according to Kuhn, is based on tradition and on "paradigms" of shared values, rationalities, and perspectives that gave shape to each of the scientific disciplines. It is thus based on epistemic values and metaphysical presuppositions that it owns but cannot justify. Far from being a complete worldview, science depends upon these larger perspectives for its working assumptions. This overarching view brought science into closer contact with philosophy and religion, since it was no longer the domain of purely objective, empirical fact derived from logic and evidence alone.

Investigations of the different methods of theology and science has also raised issues in the philosophy of language. How language is used in both physical science and theology has highlighted the importance of analogy and metaphor for both disciplines (Barbour 1974). This is especially true in subjects that study phenomena beyond human experience or full comprehension, for example, God and quantum reality. Yet both theology and quantum physics wish to make truth claims about their subjects, and this can only happen if we allow metaphorical truth and analogical predication.

MATHEMATICAL PERSPICUITY

Contemporary physical science, going back to the days of Galileo, constantly uses mathematics to model reality. Yet mathematics is a symbolic language that humans created

over centuries but never grounded in pure logic. Why should mathematics be such a powerful tool to describe physical reality? The physicist Eugene Wigner raised this question in his oft cited essay “The Unreasonable Effectiveness of Mathematics in the Natural Sciences” (1960). The structures of mathematics and the deep structure of the physical universe share a feature that makes physics possible. Especially in the area of quantum physics, the ability of mathematics to predict the outcome of difficult and complex experiments is a striking example of this aspect of the universe. For theoretical physicists, the beauty and elegance of the mathematical formulas of a theory has become a key indication of the truth of the theory. But why should this be so? Is there any a priori reason to believe that the structures of mathematics should describe and predict the nature of the cosmos so well? Religious faith, especially monotheism, provides an answer to this question. The rational mind that designed the cosmos set it on a mathematically well behaved path (macrodesign again). Whether this is *the* answer to the question is a matter of serious dispute. A possible naturalistic answer might point to the evolution of the brain. Human consciousness (including the ability to create mathematics) is the ultimate product of the very laws and principles of nature that we study—a fact that makes their harmony seem more reasonable, perhaps.

ASTRONOMY AND COSMOLOGY

From mathematics we now turn to astronomy. Three areas of this science have especially drawn the attention of philosophers and theologians: the age and size of the universe, big-bang cosmology, and the fine tuning of certain physical constants in a way that allows for the evolution of stars, planets, and people. This discussion requires the distinction between a universe and the cosmos. Here “universe” refers to our space-time domain. A universe is a spatially related collection of objects under a set of natural laws and principles. “Cosmos” refers to all the universes that have ever been or ever will be.

Our universe is expanding, and this implies that it had a beginning, when the volume of space was zero and physical time first began. Along with this discovery, astronomers in the twentieth century discovered how vast the universe really is. We are a very small part of a gigantic system of planets, stars, galaxies, and galactic clusters whose vast reaches boggle the mind. Just our galaxy alone consists of 100 million stars, and many of them may well have planets. How can we think of the Earth or our species as special in any way? Philosophers and scientists alike have embraced a kind of Stoic defiance against a

cold, dark, empty universe in which humanity has no special place. Somehow the vastness of space and time makes humans less significant, they argue. However, this ignores the fact that the God of traditional Western religion is both eternal and omnipresent. To an infinite, unbounded deity, what difference can it make how big or old the cosmos is? Any finite being will be the same relative to the creator, namely, of limited time and size. In biblical religion, the special status of human beings comes from their capacity for a personal relationship with God, not from how big, strong, or old they are. Still, the scientific conception of our universe has forced religious scholars to rethink the interpretation of the Scriptures and their understandings of the place of humans within creation. But nothing in the size and age of the universe actually falsifies the teachings of the great world religions.

The development of the concept of an initial singularity for the entire universe is one of the fascinating stories of twentieth-century physics. Suffice it to say that reluctantly, after several decades of debate, the physics community agreed that the general structure of space-time is dynamic. While such a conception of the beginning of the universe fits very poorly with the scientific materialism common in the physics community of the twentieth century, it does fit quite well with the older macrodesign view. The problem has to do with what caused the cosmos to come into existence. Even if space and time break down at the very earliest moments of space-time, we can still point to the first instances of time (which would not have any particular metric) and ask, Where did that come from? What caused it to be? Where do the structures and laws that allow such an event to take place come from? A macrodesign worldview has an answer to these questions—not a scientific one, but a religious one. The cosmos has a creator of some kind, who must be eternal, omnipotent, and omniscient (in fact, a necessary being). Note that this answer is not physical but metaphysical. It has implications for religion as well.

Philosophers who resist this implication, such as Quentin Smith and Adolf Grünbaum (2000), are forced to suggest either that (1) the earliest prematerial phase of the first quantum field that gave rise to the big bang sprang into being from nothing at all, or that (2) we can only ask questions about things that begin to exist when there is a space-time metric to measure temporality (Grünbaum), or that (3) the cosmos was just an accidental, random event in an infinite series of random events. None of these answers is especially cogent. First, a quantum field is, after all, a kind of order. Where did this order come from? If matter is structured energy, as quantum

theory teaches, the origin of structure is the key to the question of where matter comes from. The idea that all matter sprang out of an utter nothing at all—not simply no particles, but no laws, no fields, no energies of any kind—seems rather absurd. Second, to suggest that we can only think about why things come into being when there is a temporal metric to the time in question confuses physics and metaphysics. In metaphysics, it is still perfectly natural and rational to ask where the universe and its measurable temporal passage came from (and where it came from in the first place), even if there was no physical, measurable time prior to the first event of cosmic time. Finally, to suggest that the whole cosmos is purely random seems much more like an evasion of the problem than an attempt to answer the question. To postulate an infinite number of universes (or space-time domains) only to explain the design of this one is ad hoc and violates in the most extreme way Ockham's razor, or the principle of simplicity. We should not need to be reminded that this principle is important to the rationality of both physics and metaphysics. The existence and ultimate origin of the cosmos cry out for an explanation. This final issue, however, raises the question of design, and the possibility of a "multiverse," in the fundamental structures of physical reality.

FINE TUNING, DESIGN ARGUMENTS, AND THE MULTIVERSE HYPOTHESIS

In addition to the cosmological argument (the existence of the universe as evidence for the existence of God), in the 1990s there appeared a new and powerful version of the design argument that relies on certain fundamental constants in nature. It seems that for any intelligent life (including human life) to ever evolve anywhere in the universe, the exact values of some fundamental physical constants must be so precisely fine-tuned and balanced that it boggles the human imagination. For this reason John Barrow and Frank Tipler have called these physical constants "anthropic."

This quality of fine-tuning for anthropic purposes is widespread. Stephen Hawking, for example, estimates that the initial temperature of the universe at 10^{-43} second was fine-tuned to one part in a trillion. A tiny increase would have precluded galaxies from condensing out of the expanding matter; a tiny decrease would have resulted in the collapse of the universe. Such fine-tuning is also present in two constants in Einstein's equations for general relativity: the gravitational constant and the cosmological constant. It is also found in the fine-structure constant (which regulates electromagnetic interaction),

the proton-to-neutron mass ratio, the weak nuclear force, the strong force, and so forth. According to Barrow and Tipler, a 50 percent decrease in the strength of the strong force, to take another example, would make all elements necessary for life unstable.

The initial response to this problem was to develop a number of inflationary models of the big bang. According to such models (and there are many of them), matter in the very early universe (10^{-35} second) expanded faster than the speed of light but then slowed down, and this resulted in a nearly flat curvature of space and the isolation of our relatively homogeneous space-time within a larger cosmos. We should remember that these models are highly speculative and as yet have no empirical support (that is, they are mathematical and theoretical constructions). On the basis of some inflationary models, theoretical physicists have gone even farther and suggested that our cosmos may be a "multiverse." In such theories, which need much further investigation in both physics and metaphysics, our universe is one space-time domain in a vast cosmos that might contain a large number of other universes. No serious astronomer or physicist suggests that there are an infinite number of universes. But there could be an extremely large number of universes in the cosmos, and the number might be potentially infinite (that is, finite at any moment of time but open to an infinite future). If we assign laws and principles of nature randomly among all these universes in the cosmos, the fact that ours is so well fine-tuned for the evolution of intelligent life seems less surprising.

But is it less surprising? Stephen Barr (2003) has argued cogently that even if there are many, many universes in the cosmos, the fine-tuning needed across the whole range of principles and laws is so great that no finite number of universes would lower the "surprise" (the probability of our universe, against a background knowledge consisting only of the truths of reason). If Barr is even close to being right, then the multiverse hypothesis does very little to make our biologically friendly universe less surprising (or more probable). Perhaps some macrodesign scientific worldview is the most rational explanation of the order of the universe. Other options are possible, of course, for those uncomfortable with belief in some kind of creator. These options include the view that epistemic probabilities are purely subjective, and that the only real probabilities are physical ones, so that one simply cannot judge probabilities for the initial conditions of a universe. Another possibility is that our probability reasoning cannot apply to a whole universe: Any universe is just as improbable (and just as probable)

as the next one. We are extremely lucky that one universe in the cosmos of multiple space-time domains is capable of bearing life. Despite these options, or perhaps because of them, philosophers, scientists, and theologians continue to find the new fine-tuning arguments of great interest.

Alan G. Padgett (2005)

RELIGIOUS EXPERIENCE

Most of the philosophical work on "religious experience" that has appeared since 1960 has been devoted to its phenomenology and epistemic status. Two widely shared assumptions help account for this—that religious beliefs and practices are rooted in religious feelings and that whatever justification they have largely derives from them.

The majority of the discussions of the nature of religious experience are a reaction to Walter Stace, who believed that mysticism appears in two forms. Extrovertive mysticism is an experience of nature's unity and of one's identity with it. Introvertive mysticism is an experience of undifferentiated unity that is devoid of concepts and images; it appears to be identical with what others have called "pure consciousness"—a state in which one is conscious but conscious of nothing.

R. C. Zaehner argued that Stace's typology ignores love mysticism in India and the West. There are two types of introvertive mysticism—monistic (pure consciousness) and theistic. The latter is a form of mutual love that unites God and the mystic in an experience without images and with very little, if any, conceptual content. The most effective defense of a position of this sort is Nelson Pike's. Pike argues that the principal forms of mystical prayer in Christianity (quiet, rapture, and full union) are phenomenologically theistic. He defends his analysis against William Forge, who denies that the identification of the experience's object with God can be part of its phenomenological content.

Phenomenological analyses of religious consciousness presuppose that we can distinguish descriptions of religious experience from interpretations. Ninian Smart proposed two tests for distinguishing descriptions—that the accounts be autobiographical and that they be relatively free from doctrinal concepts. The question of crite-

ria remains vexed, however (see Wainwright, 1981, chap. 1).

Others have argued that, because religious experience is significantly constituted by the concepts, beliefs, expectations, and attitudes that the mystic brings to it, attempts to distinguish interpretation from description are misguided. For example, an influential article by Steven Katz contends that a mystic's experiences are largely shaped by his or her tradition. This has two consequences. First, there are no "pure" or "unmediated" mystical experiences and, second, there are as many types of mystical experiences as there are traditions.

Katz's "constructivism" has been attacked by Robert Forman and Anthony Perovitch among others. Since pure consciousness is devoid of content, it is difficult to see how it could be constituted by contents that the mystic brings to it. To argue that it must be mediated because all experience is mediated begs the question; on the face of it, pure consciousness is a counterexample to the thesis in question. Forman also argues that constructivism cannot adequately account for novelty—the fact that the mystic's experiences are often unlike what he or she expected.

Defenses of religious experience's cognitive validity have taken several forms. William Wainwright argues that mystical experiences are presumptively valid because they are significantly similar to sense experiences. Both experiences have what George Berkeley called "outness"—the subject has the impression of being immediately presented with something transcending his or her own consciousness. Corrigible and independently checkable claims about objective reality are spontaneously made on the basis of both types of experience. There are tests in each case both for determining the reality of the experience's apparent object and for determining the genuineness of apparent perceptions of it. The nature of the tests, however, is determined by the nature of the experiences' alleged objects. Since the apparent objects of religious experience and ordinary perceptual experience differ, so too will the tests for veridical experiences of those objects.

Richard Swinburne's defense of religious experience's cognitive validity is based on the principle of credulity, which roughly states that apparent cognitions are innocent until proven guilty. This is a basic principle of rationality; without it we would be unable to justify our reliance on memory, sense perception, and rational intuition. The principle implies that there is an initial presumption in favor of how things seem to us, although this presumption can be overridden. What is true of apparent cognitions in general is true of religious experiences. They too should be accepted in the absence of good

reasons for thinking them deceptive. Swinburne argues that there are none.

The most sustained defense of religious experience's epistemic credentials is William Alston's. Whereas Wainwright and Swinburne concentrate on perceptual (or perception-like) experiences, Alston focuses on perceptual practices. Doxastic (belief-forming) practices are basic when they provide our primary access to their subject matter. The reliability of a basic doxastic practice like memory cannot be established without circularity; any attempt to justify it relies on its own outputs. Alston argues that sense-perceptual practice and "Christian mystical practice" are epistemically on a par. Since both doxastic practices are basic, neither's reliability can be established without circularity. Both practices are socially established, internally consistent, and consistent with the outputs of other well-established practices. They are also self-supporting in the sense that they have the outputs we would expect them to have if they were reliable (successful predictions in the first case, for example, and moral and spiritual improvement in the second). Alston concludes that it is unreasonable to engage in sense-perceptual practice while rejecting the rationality of engaging in Christian mystical practice. The rationality at issue, however, is not epistemic. Neither practice can be shown to be epistemically rational, since it is impossible to establish their reliability without circularity. Alston intends to show only that it is practically or pragmatically rational to engage in them, although it should be noted that engaging in them involves accepting their outputs as true and therefore believing that they are reliable. Alston concedes that the existence of competing mystical practices weakens his case but denies that it destroys it. Critiques of Alston's work have tended to focus on this point (see, for example, Hasker, 1986).

The most significant attacks on religious experience's cognitive validity to have appeared since 1960 are Wayne Proudfoot's and Richard Gale's. Proudfoot argues that an experience's noetic quality should be identified with its embedded causal judgment (that the experience is caused by a tree, for example, or by God) and this judgment's affective resonance. The incorporated causal judgment has no intrinsic authority; it is merely one hypothesis among others and should be accepted only if it provides a better overall explanation of the experience than its competitors'. While the causal hypotheses embedded in religious experiences could be correct, they are in fact suspect; they appear to be artifacts of the subject's religious or cultural tradition and not products of nonnatural causes.

Proudfoot's identification of an experience's noetic quality with an incorporated causal judgment and its affective resonance is more plausible in some cases than others. Given my background knowledge, I believe that a certain sort of pain in one's tooth is caused by cavities. Believing this, and having a pain of that sort, I spontaneously form the belief that my pain is caused by a cavity. While my pain is not noetic, the experience as a whole is, since it incorporates a causal judgment. But the experience lacks "outness." It thus differs from sense perception, which (because of this quality) seems to have an intrinsic authority that noetic experiences like my toothache lack. Religious experiences are also diverse. Some, like my toothache, involve spontaneous causal attributions and nothing more. Others, however, are perception-like and have the same claim to intrinsic authority that sense perceptions do.

Richard Gale, on the other hand, argues that religious experience lacks the authority of sense experience. The only way of establishing religious experience's cognitiveness is by showing that the tests for it are similar to those for sense experience. Arguments for religious experience's cognitive validity fail because the dissimilarities are too great. Alston and Wainwright contend that these dissimilarities can be explained by differences in the experiences' apparent objects. Gale objects that explaining the disanalogies does not explain them away and that there is a "tension" or "inconsistency" in claiming that the tests are similar (as they must be if the defense of religious experience's cognitiveness is to be successful) and yet different in nature. The first point is dubious. Only relevant disanalogies count. The point of Wainwright's and Alston's explanations is to show that the disanalogies are not relevant—that is, that the features that tests for sense experiences have and tests for religious experiences lack are not ones we would expect the latter to have if religious experiences were veridical perceptions of their apparent objects.

Gale's most original (and controversial) contribution is his contention that veridical experiences of God are conceptually impossible. The argument is roughly this: Talk of veridical experiences is in place only where it makes sense to speak of their objects as existing "when not actually perceived" and as being "the common object of different" experiences of that type. Sense experiences exhibit this feature because their objects are "housed in a space and time that includes both the object and the perceiver." Religious experiences do not exhibit this feature because there are no "analogous dimensions to space and time" that house both God and the perceiver. Gale

attempts to establish this by refuting P. F. Strawson's claim that a "no space world ... of objective sounds" is conceptually possible. We could neither reidentify sounds in such a world nor distinguish between numerically distinct but qualitatively identical ones. It would make no sense, therefore, to speak of sounds as the common objects of distinct auditory experiences or as existing when unperceived. Talk of veridical experiences of objective sounds would thus be out of place. A fortiori, talk of veridical experiences would be out of place in a nonspatial and nontemporal world. Therefore, since no common space (and, on some accounts, no common time) houses God and the mystic, talk of veridical perceptions of God is inappropriate.

A few general observations about discussions of religious experience since 1960 are in order. First, most defenses of religious experience's cognitive validity have been offered by theists. Stace is one of the few who has attempted to establish the veridicality of pure consciousness and other nontheistic experiences that lack intentional structure. Second, philosophical discussions of religious experiences tend to abstract them from the way of life in which they occur and thereby impoverish our understanding of them. Whether this penchant for abstraction adversely affects the discussion of phenomenological and epistemological issues, however, is more doubtful. Finally, a philosopher's assessment of the cognitive value of religious experience is affected by his or her metaphysical predilections. For example, those who assign a low antecedent probability to theism will demand stronger arguments for theistic experiences' cognitive validity than those who do not. One's assessment of religious experience cannot be separated from one's general assessment of the relevant religious hypotheses.

William J. Wainwright (1996)

RELIGIOUS EXPERIENCE, ARGUMENT FOR THE EXISTENCE OF GOD

Arguments from Religious Experience show remarkable diversity, (a) in the sorts of experience taken as data for the argument, (b) in the structure of the inference itself, and (c) in the alleged conclusion, whether to a vague Presence, an Infinite Being, or the God of traditional Christianity.

The following exemplify some versions of the argument:

"At very different times and places great numbers of men have claimed to experience God; it would be unreasonable to suppose that they must all have been deluded."

"The real argument to God is the individual believer's sense of God's presence, the awareness of God's

will in tension and conflict with his own will, the peace that follows the acceptance of God's command."

"Experiences of meeting God are self-authenticating: They involve no precarious chain of inference, no sifting of rival hypotheses. They make unbelief logically absurd."

"In itself, religious experience is neither theistic nor pantheistic, Christian nor Buddhist. All these distinctions are *interpretations* of the experience. By itself, religious experience testifies to something far less definite but still infinitely valuable—the insufficiency of all materialisms and naturalisms."

If we compare any of these arguments with the Ontological, Cosmological, and Teleological arguments, important differences in their logic and history can readily be shown. Arguments from Religious Experience are clearly not a priori, like the Ontological Argument, and whereas the Cosmological and Teleological arguments work from premises that affirm highly general facts about the world (that it exists, that it is purposefully ordered), Arguments from Religious Experience rely on far more particularized and elusive premises than these. Not all men have (or are aware of having) distinctively religious experiences, and to those that do have them religious experiences are apt to be short-lived, fugitive sets of events that are not publicly observable.

Despite this slipperiness, the Argument from Religious Experience has attracted some theologians who have been skeptical about the more rationalistic "proofs." In the course of the eighteenth century these proofs received formidable criticism from Immanuel Kant and David Hume. The Ontological Argument was shown to be radically confused over the logic of "existence," and (in Kant's account) the Cosmological and Teleological arguments themselves presuppose the Ontological. Even more important, Kant and Hume together produced a general weakening of confidence that any survey of the observable cosmos (including "the starry heavens above") could yield premises powerful enough to argue to an infinite, unconditioned, all-good deity. Kant turned to "inner" experience, to our awareness of the moral law, and argued that the moral life is intelligible only if we postulate God and immortality.

Although a number of writers followed Kant in arguing from inner moral experience, many others, while accepting the shift from outer to inner, based their inference on a distinctive class of religious experiences. If we describe this shift, in general terms, as a move from objective to subjective, from surveying the world at large for evidences of God to focusing attention on the personal

and existential, it clearly was a shift of the greatest moment and one that still helps to determine our contemporary climate of theological thought. We human beings are not stars or electrons—the argument goes—and we cannot experience or guess the role of star or electron in the divine economy. But we are persons, and we are directly aware (or some of us are) of a meeting of person with Person in religious experience.

Thinking back, however, to the post-Humean, post-Kantian period, the centering upon inner experience can be seen as one aspect of the romantic movement's protest against the Enlightenment, the new concern for subjectivity, the life of the emotions and intuitions of the individual. The most important and most seminal single figure here is Friedrich Schleiermacher (1768–1834), with his bold insistence on the primacy of religious feeling—particularly the feeling of utter creaturely dependence—and his distaste for religious doctrines or arguments entertained in a purely intellectual manner, as mere ideas, lacking the life and authority of experience.

OBJECTIONS TO THE ARGUMENT

Prima facie it seemed a reasonable and empirically sound enterprise to establish arguments for God upon claims to have actually experienced him, to have “seen” him, “met” him, encountered him in a personal relation. But there are in fact several directions from which it can be challenged.

Orthodox and neoorthodox theologians tend to object that the content of religious experience is too indeterminate to yield clear knowledge of the God of Christianity. The case for Christianity must not be allowed to rest on the deceptive and elusive emotions of religious people. It rests on the revealed Word of God, on the Person of Jesus Christ as disclosed in the Scriptures, not as constructed out of the assorted emotions of the devout. The working of the Holy Spirit cannot be correlated with the experiencing of peculiar feelings, even uplifting ones.

A second familiar objection is that although we certainly do have religious experience, we cannot employ it as the premise of an argument to God. The relationship between man and God—an I-Thou (in Martin Buber's phrase), personal relationship—is maintained by faith alone. The conception of superseding faith through a proof of God's existence forgets the irreducibly personal nature of encounter between man and God.

The objector may be making a religious claim, that it is religiously improper to attempt to replace faith by rational argument, or his point may be a logical one, that

God—being “pure” person, having nothing bodily or thinglike in his nature—cannot be shown to exist in the way things can be shown to exist.

Suppose, again, we take the Argument from Religious Experience as an explanatory hypothesis; then a skeptical critic may deny that the existence of God is the likeliest, or simplest, or most intelligible, explanation of the experiences. We cannot be intellectually compelled to posit God if more economical and naturalistic explanations can be found—psychoanalytic accounts, it might be, or accounts in terms of individual suggestibility or the influence of religious expectations or tradition.

Last, a critic may concentrate on the conceptual difficulties in the idea of God, for if the argument as a whole is to be sound, its conclusion (“therefore God exists”) must be intelligible and free of inner contradictions. This objection may bewilder and disappoint the arguer-from-experience. To him one of the chief apparent advantages in the argument is that its direct appeal to experience bypasses logical or metaphysical complexities. But some element of interpretation, and therefore some application of concepts, must take place when an experience is taken to be an encounter with God. Wherever concepts are handled, they can also be mishandled. Inner contradictions in the claim to experience God could invalidate the interpretation of the experience.

NATURE OF RELIGIOUS EXPERIENCES

What, more exactly, are religious experiences? Descriptions of religious experiences can be heavily loaded with doctrinal, even sectarian, interpretation or can be almost entirely free of it. Their impact may fix one's attitudes and evaluations for a lifetime or for only a brief period. They may not only be benign and optimistic, as we have so far assumed, but can also—with no less intensity—be pessimistic and grim. They may involve conversions to a religious orthodoxy or conversions away from one. Consider the following experiences, neither of which is more than minimally interpreted, and both of which are certainly in an important sense religious. The first is from Lev Tolstoy's *War and Peace*, at the point where Prince Andrew has been wounded in the Battle of Austerlitz.

He opened his eyes, hoping to see how the struggle of the Frenchmen with the gunners ended.... But he saw nothing. Above him there was now nothing but the sky—the lofty sky, not clear yet still immeasurably lofty, with grey clouds gliding slowly across it. “How quiet, peaceful and solemn, not at all as I ran,” thought Prince Andrew—“not as we ran shouting and fight-

ing.... How was it I did not see that lofty sky before? And how happy I am to have found it at last! Yes! All is vanity, all falsehood except that infinite sky. There is nothing, nothing but that. But even it does not exist, there is nothing but quiet and peace. Thank God!”

The second is from Leonard Woolf’s autobiographical work, *Sowing* (1960). At the age of eight, the author was sitting in a garden enjoying the fresh air after a train journey. He watched two newts basking in the sun.

I forgot everything, including time, as I sat there with those strange, beautiful creatures, surrounded by blue sky, sunshine, and sparkling sea. I do not know how long I had sat there, when, all at once, I felt afraid. I looked up and saw that an enormous black thunder cloud had crept up and now covered more than half of the sky. It was just blotting out the sun, and, as it did so, the newts scuttled back into their hole.... I felt something more powerful than fear, once more that sense of profound, passive, cosmic despair, the melancholy of a human being eager for happiness and beauty, powerless in face of a hostile universe.

Turning to theistic types of experience, we can start from the very basic experience of wonderment, notably wonderment at there being any world at all. This may pass into the sense that the world owes its existence to, and is maintained in existence by, something “beyond,” “outside” the world itself, a Being whose nature is utterly remote from the world, yet whose activity and energy are perceptible within the world, as a disturbing, awesome, and thrilling presence. Rudolf Otto’s concept of the “numinous” gathers together these ingredients of mystery, dread, and fascination and emphasizes very properly the qualitative distinctiveness and elusiveness of such experience (*The Idea of the Holy*, passim). No set of categories can neatly contain it: The person who has never known it can barely understand the claims of the person who has.

Religious experiences can be generated by perceptions of individual objects (a grain of sand, a bird), by a train of events, by actions—for instance, the memorable account of Jesus setting his face to go to Jerusalem to his Passion. Even a passage of philosophical reasoning may do this, as when someone contemplates the incompleteness of all explanation, the intellectual opacity of space and time, and feels compelled—with a sense of mystery—to posit a divine completeness and unity.

Closer to the province of morality are experiences of divine discontent, interpreted as intimations of God’s existence and call to moral endeavor, the conviction of sin correlative to a sense of God’s own holiness, the sense of divine aid in the rectifying of one’s moral life, and, in Christian evangelical terms, a sense that one has been redeemed or saved by God’s action on man’s behalf.

The overall impression is of the immense diversity of religious experiences. They are indeed linked by complex webs of “family resemblances” (to use Ludwig Wittgenstein’s phrase)—resemblances of attitude, emotional tone, alleged content—but if we ask what all of them have in common, the answer must be meager in content: perhaps only a sense of momentous disclosure, the sense that the world is being apprehended and responded to according to its true colors. What is actually being observed or contemplated can never (logically) be the whole universe, yet the quality of religious experience is such that it does seem to imply something about the whole.

EPISTEMOLOGICAL STATUS OF RELIGIOUS EXPERIENCES

Our sampling of religious experiences may help to deliver us from the dangers of oversimplification, but it cannot by itself determine whether arguments to God based upon them are valid. Clearly, not all the experiences we have mentioned could yield data with which a theistic argument could start. Some, such as that of Woolf quoted earlier, are decidedly *antitheistic*. But there is a further set of differences among them that must be noted at this stage, differences of an epistemological kind.

When someone speaks of his religious experience, he may be using the word *experience* as it appears in such phrases as “business experience,” “driving or teaching, etc., experience.” He has found the religious pattern of life viable; he has interpreted a multiplicity of events in its categories, and these categories have proved durable. There is the suggestion that the person with religious experience in this sense has been confirming his faith by living it out over a substantial stretch of his life—furnishing data for a pragmatic proof of God’s existence.

In other cases the experiences are of much shorter duration, often judgments or quasi perceptions accompanied by certain religious emotions, alleged cognitive acts or intuitions in which the necessity of God’s existence is “seen” and an awesome emotive response is elicited simultaneously. Again, the language used may be nearer to that of perceiving—*seeing God* (not just seeing *that* God exists). There is a claim to knowledge of God by “acquaintance,” rather than “description.”

Some cases resemble the dawning of an aspect or interpretation, as when we recognize a person in a poor light or make out a pattern in what looked like a maze of lines. It can be like a sudden reading of the expression on a face, the face, as it were, of the universe, or like a realization of meaning, as when one sees the point of a poem with which one has long been verbally, but only verbally, familiar. In the light of this disclosure, a new orientation and purposeful organization of life may take place. Energies hitherto dissipated or in mutual conflict are rallied and integrated.

Feelings or emotions may predominate in religious experience, but even so, perception and judgment are almost always involved as well. Feelings are often “feelings *that ...*,” surmises, and in that sense feelings involve judgment, have an essential component of belief. Part of what it is to have an emotion is to see and appraise one’s situation in a particular way. (“I feel remorse for doing *x*,” for example, presupposes “I did *x* freely” and “*x* was morally wrong.”) It is only with twinges, frissons, aches, and such like that no appraisal of the situation need (logically) be made; these, in any case, could furnish only very weak premises for a theistic argument. Their occurrence can be due to a great variety of causes immanent in one’s own organism and one’s environment, and they can hardly, without supplementation, force one to posit a transcendent cause.

Obviously the structure (and maybe the validity) of an Argument to God from Religious Experience will vary enormously according to what epistemological type of experience is taken as the starting point, and in the literature this is often hard to discern.

VERIFIABILITY OF RELIGIOUS EXPERIENCE

If someone claims to have discovered, perceived, become aware of an ordinary sort of object, we usually know what to do about checking his claim. If we are told that there is a frog in the garden pond, we know what it will be like to confirm this or to find it untrue. We know how to investigate whether it was Smith we saw in the dim light, whether we did hit the right answer to a sum or cried “Eureka” too soon. But when someone claims to have direct awareness of God, to encounter, see, or intuit the divine, we are not able to suggest a test performance of an even remotely analogous kind. The more developed and theologically sophisticated the conception of deity is, the more it eludes and resists any such check.

This being so, some critics have pointed out a disturbing resemblance between claims to experience God

and a certain other range of statements that are not publicly testable—namely, psychological statements such as “I seem to hear a buzzing noise,” or “I seem to see a patch of purple.” If statements like these cannot be refuted, it is only because they make no assertions about what exists, beyond the experiences of the speaker at the moment he speaks. But the person who says he has direct and certain experience of God wishes to claim irrefutability and to affirm at the same time something momentous about what exists. Can this be done? Or would it take a far more elaborate and many-stranded apologetic to give effective backing to these claims—especially the claims to objectivity?

One might try to obtain this support by compiling records of numerous experiences of the same general kind and treating them as cumulative evidence for the truth of claims to experience God. Without doubt there is an impressive mass of such records within the Judeo-Christian tradition. Other religious traditions, however, can also produce their own very different records—of the various well-ordered phases in the quest for nirvana or for mystical union with a pantheistic object of worship.

Are these differences, however, real incompatibilities; do they correspond to genuinely different sorts of religious experience? Or are the experiences basically the same, though differently interpreted? On this it is extremely hard to give any confident answer. Part of the difficulty is that most of the developed religions contain several strands in their conceptions of the divine. Christianity, for instance, seeks to unite numinous and mystical views of God: God is “remote” and “other,” yet also mystically “near.” What can be said again is that any common elements must be very indeterminate in content and able to bear great variety of interpretation—to be taken, among other things, as the disclosure of a state or spiritual goal (nirvāṇa) or of a personal or suprapersonal God. We have seen how an experience may have a minimal—quite undoctinal—interpretation and yet be religious in a broad sense. But from such an experience alone one can hardly infer anything so definite as the God of theism. Unfortunately, the interpretations that supplement the experience are conceptually intricate and involve all the uncertainty and fallibility of philosophical and theological speculation. In this region we are far removed from the ideals of immediacy, directness, and self-evidence.

Yet a critic who claimed that the Argument from Religious Experience was thereby refuted would be missing the mark. The theist could insist that a much too crude notion of “interpretation” has so far been used, one

that suggests, falsely, that there is a merely external and almost arbitrary relation between having and interpreting an experience.

The full impressiveness of the theistic case appears only when we survey the historical development of religious experience in the direction of Christian monotheism. As the idea of deity evolves, from finite and local numen to infinite and omnipresent Lord, from the god of a tribe or nation to the Ruler of all nature, from the deity concealed in holy tent or temple to the one God beyond all phenomena whatever, religious experience is itself simultaneously transformed. It is transformed not haphazardly but so as to produce a crescendo of numinous intensity, a constant refining away of merely superstitious and idolatrous awe at objects unworthy of worship, and the arrival of a distinctive, lofty note of adoration. Experience and interpretation here advance in indissoluble unity. It is argued that this historical development provides material for a more adequate argument to God—one in which the risks of fantasy and subjectivism are much reduced.

Impressive this is, and it may well be the truth of the matter. We must notice, however, that we are now looking at a much more complex piece of argument than the claims of individuals to have direct experience of God. New logical problems appear at several points. Can we be confident, for instance, that an intensification of numinous experience is necessarily a sign that we have a more adequate disclosure of God and not simply that we have constructed a more adequate and awesome idea of God? (This is the question that also calls in doubt any purely pragmatic philosophy of religion.) Again, sometimes an artist, or a school of artists, succeeds in progressively clarifying and intensifying an original vision or the expression of some distinctive emotion. But success in this (“now he has brought the theme to full explicitness,” for example) is not necessarily correlated with a progress in discovery about the world. Can we be sure that the development of numinous awareness is different in this vital respect?

The person with theistic religious experience is assured that it is different. But the sense of assurance, the “Aha!” experience, the penny dropping, the light dawning—these are very unreliable guides to truth, validity, or value. Not the most tempestuous sense of poetic inspiration can guarantee that a good poem is being brought to birth, nor can any of these conviction-experiences by itself authenticate its related judgments. It is enough to recall how often incompatible judgments are made with equal assurance on each side. Yet it is not easy to formu-

late a version of the Argument from Religious Experience that does not rely crucially on a sense of conviction. Even when appeal is made to the pattern of development toward theism, and thus to a far wider range of phenomena than in any argument from the experience of an individual, still the issue of objectivity—that we are coming to know God, not simply an idea of God—seems to hang upon the fallible, illusion-prone assurance of the subjects. On the other hand, to point this out is to draw attention only to the risk, not to the certainty, of being wrong. A religious person may realize, and be prepared to accept, this measure of risk.

Could we escape the uncertainty, by claiming that genuine experience of God is necessarily followed by a godly life, whereas illusory experiences betray themselves by the absence of any practical fruits? Hardly; there might well be a positive correlation between genuine experiences and godliness, but in fact they are not necessarily related. Lapses, moral failures, are always open to human beings, and one cannot rule out by definition the possibility of a man’s being both morally remarkable and atheistic.

But, one might argue, is the situation vis-à-vis God any worse in principle than the situation vis-à-vis material objects, such as tables and chairs? Our traffic with these consists in having actual experiences (visual, tactual, etc.) and ordered expectations of future and possible experiences. Where our experience has this sort of structure and can thus be the subject of intelligible discourse, we confer on it the status of objectivity without more ado. But theistic experience certainly occurs, and it too has its structure of expectations.

If we can bring out the difference between these cases (and the peculiar difficulty of the religious case), we shall be showing more clearly than hitherto that the Argument from Religious Experience is most intimately involved in problems of logic and meaning—problems that at first seem alien to its empirical appearance. With a material object (say, a cube) there are quite intricate but intelligible ways in which we come to see it as a single object out-in-the-world. It is given unity most obviously by possession of perceptible limits and boundaries and by the manner in which its several surfaces can be seen and felt to connect with one another. Moreover, we have mastered the laws of perspective and so can anticipate and understand variations in our perceptions of the object, owing to our own variable positions as observers. Such variations do not, therefore, impugn the assertion that the object exists in the world external to us.

With God, who is not a finite material object, there can be no inspecting of boundaries or surfaces. And if part of what we mean by “God” is “an infinitely and eternally loving Being,” no conceivable experience or finite set of experiences could by itself entitle us to claim that we had experienced such a being. We might well report experiencing “a sense of immense benevolence toward us,” “a sense of complete safety and well-being,” but from their intensity alone one could not rigorously conclude, “Therefore I am in touch with an infinitely and eternally loving God.” From the intensity of a human love one cannot infer, “This love will endure,” and without bringing in a supplementary doctrine of God’s attributes (not derived from experience) one could no more legitimately do so in the religious case.

Material objects, of course, are sometimes observed in unfavorable perceptual conditions—at a great distance, half-concealed, and so on. Imagination must “fill in” the perceptual gaps as best it can, until conditions improve. Analogous thought models are indeed employed in theological discourse, but they are peculiarly difficult to assess. The Christian theologian is normally most ready to admit that we can neither perceive nor imagine how the various attributes of God unite in a single being (if he is to be called “a being” at all). A fair measure of agnosticism here is compatible with full Christian belief. But it may not be compatible with a reliance upon an Argument to God from Religious Experience, if this is one’s chief apologetic instrument. Unless the principles that confer unity and objectivity are able to be collected from the experiences themselves (which seems not to be possible), we have to look elsewhere for them, and the argument is in this respect shown to be inadequate. But it is not, on that account, proved useless, for if it cannot demonstrate the existence of God unaided, it might still function as a necessary auxiliary of other arguments—for example, the Cosmological Argument.

One might be forced to a deeper agnosticism than that to which we have just alluded—deeper in that it dares to affirm scarcely anything at all about the focus (or focuses) of religious experience, whether personal or impersonal. Yet with a minimal ontological commitment it might still set great value on certain religious experiences and seek after them. The attempt to work out a coherent and systematic theological interpretation would be quite abandoned.

This would save something, but assessing just how much to expect from a religious agnosticism like this would be a difficult task. The bigger the area of agnosticism, the smaller the area of legitimate religious expecta-

tions, such as that of ultimately seeing God “face to face” or of being received by him into glory. As we have more than once observed, the relation between experience and what the experience is taken to be is a most intimate one; the experiences of a Christian and those of a religious agnostic could both be valuable but could not be identical.

PSYCHOLOGICAL EXPLANATIONS

Is it not more enlightened, however, to deny that these experiences really disclose anything about the world? Psychoanalytic research has, after all, revealed many situations in which interior mental events are projected upon the world and are furnished with all the assurance of objectivity, the full sense of “givenness.” One does not have to accept the entire Freudian account of religion to see plausibility in its central claim that early parent-child relations of “creaturely” dependence and reverence, with their tensions between love and fear, can yield the unconscious material from which experiences of God-man relations are fashioned. To accept this claim is not necessarily to reduce all religion to neurosis or worse. For it is absurd to class together the person who attains a stable religious solution to his conflicts and the person who retreats to genuine neurosis, developing, say, obsessions, compulsions, or delusions of persecution. Sigmund Freud certainly went further in his naturalistic explanation of religious experience, being prepared to reduce God to an illusory parent substitute. It may be possible, however, to invert the Freudian account of religious experience and, instead of seeing God as a father substitute, to see human fathers as God substitutes and the human experience of love as training for loving God. The close psychological relation between love of man and love of God would thus have its skeptical sting removed. It may be argued, again, that naturalistic and Christian explanations are compatible: God may elicit from us an effective response to his existence without making use of anything but our natural human equipment of senses, desires, emotions. Even mechanisms of projection can be involved and the projected image of deity be yet a trustworthy symbol of a God who does in fact exist. It is clear from all this that depth psychology does not provide a self-sufficient, decisive refutation of theism.

Nonetheless, depth psychology troubles and disturbs the Arguments from Religious Experience, and so do the very attempts to reconcile it with Christian belief. These virtually admit that the religious experiences might occur much as they actually do occur—without there being a God—in other words, that naturalistic explanations are

possible. There seems no way, at the experiential level, of settling the really urgent questions, most of all the following: Do we have in theistic experience mere projection? Or do we have a projection matched by an objectively existing God?

Bibliography

WORKS ON THE PSYCHOLOGY OF RELIGION

The following works have important implications for the Argument from Religious Experience:

- Freud, Sigmund. *The Future of an Illusion* (1927). Translated by W. D. Robson-Scott. London: Hogarth Press, 1928; paperback ed., Garden City, NY, 1957.
- Freud, Sigmund. "Obsessive Acts and Religious Practices" (1907). In *The Standard Edition of the Complete Psychological Works of Sigmund Freud*, translated by James Strachey, ed., in collaboration with Anna Freud. 24 vols. New York: Macmillan, 1953–1963.
- Freud, Sigmund. *Totem and Taboo* (1913). Translated by A. A. Brill. New York: New Republic, 1927. Also translated by James Strachey. New York: Norton, 1952.
- James, William. *Varieties of Religious Experience*. London: Longman, 1902.
- Jung, C. G. *Psychology and Religion*. New Haven, CT: Yale University Press, 1938; paperback ed., 1960.
- Philp, H. L. *Freud and Religious Belief*. London: Rockliff, 1956.
- Thouless, R. H. *An Introduction to the Psychology of Religion*. Cambridge, U.K.: Cambridge University Press, 1923; reprinted, 1936.

RELEVANT THEOLOGICAL WORKS

- Raven, C. E. *Natural Religion and Christian Theology*. Vol. II. Cambridge, U.K.: Cambridge University Press, 1953.
- Schleiermacher, Friedrich. *Der christliche Glaube*. Berlin, 1821–1822. 2nd ed. translated by H. R. Mackintosh and J. S. Stewart as *Christian Faith*. Edinburgh: T. and T. Clark, 1928.
- Schleiermacher, Friedrich. *Die Religion. Reden an die Gebildeten unter ihren Verächtern*. Berlin, 1799. Translated by John Oman as *On Religion: Speeches to Its Cultured Despisers*. London: K. Paul, Trench, Trubner, 1893; reprinted, Gloucester, MA, 1958; paperback ed., New York: Harper, 1958.
- Tennant, F. R. *Philosophical Theology*. Vol. I. Cambridge, U.K.: Cambridge University Press, 1928.

PHILOSOPHICAL STUDIES

The following works explore the relation between religious experience and religious belief or contain relevant ideas and arguments:

- Buber, Martin. *Ich und Du*. Leipzig, 1923. Translated by R. Gregor Smith as *I and Thou*. Edinburgh, 1937.
- Campbell, C. A. *On Selfhood and Godhood*. London: Allen and Unwin, 1957. On Rudolf Otto see Lecture 16.
- Hick, John, ed. *Faith and the Philosophers*. New York: St. Martin's Press, 1964.
- Holland, R. F., and J. M. Cameron. "Religious Discourse and Theological Discourse." *Australasian Journal of Philosophy* 34 (1956): 147–163, 203–207.
- Hook, Sidney, ed. *Religious Experience and Truth*. New York: New York University Press, 1961.
- Lewis, H. D. *Our Experience of God*. London: Allen and Unwin, 1959.
- Lewis, H. D., and C. H. Whiteley. "The Cognitive Factor in Religious Experience." *PAS*, Supp. 29 (1955): 59–92.
- Martin, C. B. *Religious Belief*. Ithaca, NY: Cornell University Press, 1959.
- Otto, Rudolf. *Das Heilige*. Breslau: Trewendt and Granier, 1917. Translated by John W. Harvey as *The Idea of the Holy*, 2nd ed. London, 1950.
- Smart, Ninian. *Reasons and Faiths*. London: Routledge and Paul, 1958.
- Smith, N. Kemp. "Is Divine Existence Credible?" *Proceedings of the British Academy* 17 (1931).

RELIGIOUS INSTINCT

See *Common Consent Arguments for the Existence of God*

RELIGIOUS LANGUAGE

Utterances made in religious contexts are of many sorts. In the performance of public and private worship men engage in acts of praise, petition, thanks, confession, and exhortation. In sacred writings we find historical records, dramatic narratives, proclamations of law, predictions, admonitions, evaluations, cosmological speculations, and theological pronouncements. In devotional literature there are rules of conduct, biographical narratives, and introspective descriptions of religious experience. Philosophical discussions of religious language have concentrated on a restricted segment of this enormous diversity, namely, theological statements, that is, assertions of the existence, nature, and doings of supernatural personal beings.

There are two reasons for this emphasis. First, the crucial problems about religious language appear in their purest form in theological statements. If we consider a petitionary prayer or a confession, what is puzzling about it is not the act of petition or confession, but the idea of addressing it to God, and God answering it. It is the concept of communication with a supernatural incorporeal person that seems unclear. And this lack of clarity is most apparent in the statement that there exists a God who communicates with men in various ways. We may say that the difficulties in understanding other forms of religious language all stem from obscurities in statements about God.

The second reason for philosophical concentration on theological statements lies in the fact that the philosophy of religion is primarily concerned with questions of justifiability, significance, and value. And it has generally been supposed that whether religion is a justifiable form of human activity largely depends on whether there are sufficient grounds for accepting the theological statements on which it is based. Christianity is a justifiable

institution if and only if we are warranted in accepting the proposition that the world is created and governed by an omnipotent, perfectly good personal deity who has revealed himself to men in the Bible. Thus the philosophy of religion is largely taken up with examining the grounds of religious statements. And it is when we do this that we become most acutely aware of the puzzling aspects of religious language. When we make a determined effort to decide whether it is true that God created the physical universe, it is difficult to avoid realizing how unclear what we are saying is, what implications it has, what it logically excludes, and what would count for or against it. Thus the philosophical investigation of religious language focuses on those indeterminacies in theological statements that hamper attempts to find rational grounds for acceptance or rejection.

MEANING OF THEOLOGICAL PREDICATES

Most philosophers who have concerned themselves with the problem have located the difficulties of religious language in the predicates of theological statements. (What does “good” mean in “God is good”?) It may seem that we should start with the subject of the statement, with the concept of God. But there is really no alternative to starting with the predicates. For the only way to make clear what one means by “God” is to provide an identifying description, such as “the creator of the universe”; and to understand that phrase one must understand the predicate “created the universe” as applied to God. Theological predicates can be divided into negative (infinite, nontemporal, incorporeal) and positive. The positive predicates can be concerned either with attributes (good, wise, omniscient) or with actions (makes, forgives, speaks, watches over). Negative predicates present no special difficulty, but in themselves they are clearly insufficient to give any positive conception of the deity. Of the positive attributes we shall concentrate on attributions of action, partly because action terms pose more severe problems, partly because other attributes are dependent on them. (To say that God is wise is to say that he acts wisely; if we cannot understand what it is for him to perform one or another action, we cannot understand the attribution of wisdom to him.)

DERIVATION AND APPLICATION. When one reflects on the use of predicates in theological statements one comes to realize two fundamental facts: (1) this use is necessarily derivative from the application of the predicates to human beings and other observable entities; (2)

the theological use of predicates is markedly different from the application of predicates to human beings.

Theological predicates are derivative primarily because it is impossible to teach theological language from scratch. How would one teach a child what it means to say "God has spoken to me" without first making sure that the child knows what it is for a human being to speak to him? In order to do so one would have to have some reliable way of determining *when* God was speaking to him, so that when this happens one could say to him, "*That* is what it is for God to speak to you." And even if we admit that God does speak to people from time to time, there is no way for one person to tell when God is speaking to another person unless the other person tells him, which would require that the other person have already mastered the theological use of language. Hence there is no alternative to the usual procedure of teaching the theological use of terms by extension from their application to empirically observable objects.

As for the difference in the use of predicates as applied to God and to human beings, there are many ways of seeing that the terms cannot have quite the same meaning in both cases. If, as in classical Christian theology, God is conceived of as not in time, then it is clear that God's performance of actions like speaking, making, or comforting is something radically different from the temporally sequential performance of actions by human beings. St. Thomas Aquinas in his famous discussion of this problem based the distinction between the application of predicates to human beings and the application of predicates to God on the principle that God is an absolute unity and that, therefore, various attributes and activities are not distinguishable in God as they are in men. But even if we allow God to be temporal and straightforwardly multifaceted, we are left with the corporeal-incorporeal difference. If God does not have a body, it is clear that speaking, making, or comforting cannot be the same thing for God as for man.

This leaves us with a serious problem. We must show how the theological use of these terms is derived from their nontheological use. Until we do, it will be unclear just what we are saying about God in such utterances. The usual way of dealing with this problem is by cutting out the inapplicable portions of the original meaning of the terms, leaving the remainder for theology. Thus, since God is incorporeal, his speaking cannot involve producing sounds by expelling air over vocal cords. What is left is that God does something that results in the addressee having an experience of the sort he would have if some human being were speaking to him. The nature of the

"something" is deliberately left vague. Since God is a pure spirit, it will presumably be some conscious mental act; perhaps an act of will to the effect that the addressee shall have the experience of being told such-and-such. More generally, to attribute any interpersonal action to God is to attribute to him a purely mental act that has as its intended result a certain experience, like the one that would result from such an action on the part of a human being.

This account may throw some light on the content of statements about God, but religious thinkers have become increasingly dissatisfied with it. For one thing, it represents theological statements as metaphysical speculations and does little to illuminate the ways they fit into religious activity. Having postulated a pure immaterial substance performing mental acts that, miraculously, have effects in human experience, how do we go about getting into communication with this immaterial substance? Why should it be worshiped at all, and if it should, why in one way rather than another? Moreover, this line of reasoning is not helpful in our efforts to verify theological statements. It offers no hints on how we might determine whether our statements are true, or even whether there is such a being that performs the actions in question.

VERIFIABILITY OF THEOLOGICAL STATEMENTS

Recent discussions have concentrated on the problem of verifiability. In the last few decades a great many philosophers have come to accept some form of the "verifiability theory of meaning," according to which one is making a genuine factual assertion, a real claim as to the way the world is, only if it is possible to conceive of some way in which what he is saying can be shown to be true or false by empirical observation. Applying this theory to theology, it has been argued that since an empirical test is in principle impossible to carry out for statements about a supernatural incorporeal personal deity, these statements cannot be regarded as straightforward factual assertions, but must be interpreted in some other way.

John Wisdom in his influential essay, "Gods," analogizes the function of theology to the following situation. Two people return to a long-neglected garden and find some of the old flowers still surviving among the weeds. One suggests that some gardener has been caring for the plot, and the other expresses doubt about this. On investigation, it turns out that no one in the vicinity has ever noticed anyone working on the garden. Moreover they discover that gardens left to their own devices often take

this form. But the first man does not abandon his hypothesis. Instead he expresses his belief that someone who is not discernible by the senses comes and cares for the garden, carrying out designs he and his companion do not fully grasp. At this point the first man has modified his “gardener” hypothesis to the point at which it is no longer susceptible to empirical confirmation or refutation. No matter what is or is not discovered empirically, he will continue to hold it. In this case it seems plausible to say that he is no longer expressing a belief about actual objective events. If he were, he would be able to imagine, however inadequately, some way in which the existence or nonexistence of these events would be revealed to our experience. He is, rather, expressing a “picture preference.” It is rewarding to him to think of the situation as if a gardener were coming to take care of the flowers. If beliefs about God are equally refractory to empirical test, it would seem to follow that they too must be interpreted otherwise than as straightforward matters of fact. (Wisdom, however, does not commit himself to this conclusion.)

In considering the “verificationist” challenge to theology, we must scrutinize both premises of the argument: (1) theological statements are not susceptible to empirical test; (2) if they are not empirically testable they cannot be construed as factual assertions that can be assessed as true or false.

ARE THEY EMPIRICALLY TESTABLE? The question of whether theological statements are subject to empirical test is quite complicated. If we rule out mystical experience as a means of observation, then it is clear that statements about God cannot be tested directly. But science is full of hypotheses about unobservable entities—electromagnetic fields, social structures, instincts—which verificationists accept as meaningful because they can be tested indirectly. That is, from these hypotheses we can draw implications that can themselves be tested by observation. The question is whether directly testable consequences can be drawn from theological statements. We can phrase this question as follows: Would we expect any possible observations to differ according to whether there is or is not a God? It would clearly be unreasonable to require of the theologian that he specify a set of observations that would conclusively prove or disprove his assertions. Few, if any, scientific hypotheses could meet that requirement. The most that could reasonably be demanded is that he specify some observable states of affairs that would count for or against his assertions.

One thing that makes this problem difficult is the fact that on this point religious belief differs at different times and places. Supernatural deities have often been thought of as dealing in a fairly predictable way with contingencies in the natural world and human society. Thus in many primitive religions it is believed that the gods will bring abundant crops or victory in battle if they are approached in certain ways through prayer and ritual. Even in as advanced a religious tradition as the Judeo-Christian, it is believed that God has certain fixed intentions that will result in prayers being answered (when made in the right spirit and under proper conditions) and will result in the final victory of the church on earth.

It would seem that such expectations provide a basis for empirical test. Insofar as they are fulfilled, the theology is confirmed; insofar as they are frustrated it is disproved. However, things are not that simple. Even in primitive communities such tests are rarely allowed to be decisive; the empirical implications are hedged around with a variety of escape clauses. If the ritual dances are held and still the crops fail, there are several alternatives to abandoning traditional beliefs about the gods. Perhaps there was an unnoticed slip somewhere in the ritual; perhaps devils were conducting counterrituals. More sophisticated explanations are employed in the more advanced religions. For example, God will answer prayers, but only when doing so would be for the true good of the supplicant.

Moreover, as science develops, religion comes to be more concerned with the personal life of the worshiper and less concerned with prediction and control of the course of events. Among religious intellectuals today such predictions as are still made are clearly not testable in practice, because of their lack of specificity (“all things will work together for the good for those who love God”), their enormous scope (“everything in the world contributes to the development of moral personality”), or their inaccessibility (“after death we shall see God face to face”). Nevertheless, it seems that within religion there are strong barriers to completely divorcing belief in God from the expectation of one event rather than another; and so long as there is some connection of belief with testable predictions, however tenuous, it would be a mistake to think of religious statements as absolutely unverifiable in principle.

ARE THEY ASSERTIONS OF FACT? As to whether a statement that cannot be empirically tested must not be construed as an assertion of fact, a theologian might well challenge the application of the verifiability theory to the-

ology. If God is supernatural, we should not expect his behavior to be governed by any laws or regularities we could hope to discover. But then we could never be certain that, for example, the statement that God loves his creatures would ever imply that a war should have one outcome rather than another. This would mean that, according to the verifiability theory, it would be impossible for us to make any statements, even false ones, about such a being. But a theory that would prevent us from recognizing the existence of a certain kind of entity, if it did exist, would be an unreasonable theory.

NONASSERTIVE INTERPRETATIONS

Be that as it may, a number of philosophers have been so impressed by these difficulties over verifiability that they have tried to construe theological utterances as something other than straightforward factual assertions. Attachment to the verifiability theory is not the only motivation behind the development of such theories. There are those, like George Santayana, who, without holding that theological sentences are factually meaningless, are convinced that as factual assertions they are false, but still are unwilling to abandon traditional religious discourse. They feel that somehow it has a valuable function in human life, and in order to preserve it they are forced to reinterpret it so that the unwarranted factual claims are expunged. Still another motivation is the hope that this will contribute to the resolution of the problem mentioned earlier, that of specifying the way predicates are used when they are applied to God. As we saw, attempts to give an illuminating definition of theological predicates have not been wholly successful, and this can be taken to indicate that a different sort of approach is needed.

One such line of investigation takes sentences as its units rather than words. It focuses on the kind of linguistic act performed when theological sentences are uttered, rather than on the meaning of words in theological contexts. Instead of asking what “forgives” means when applied to God, we ask what linguistic action is performed when one uses the sentence “God forgives the sins of those who truly turn unto him.” It is this sort of question one is asking when one wonders whether theological sentences make factual assertions and, if not, what they are used to do. If we could answer this question we would have made sufficiently clear how words are being used in theological sentences without having to define special senses for constituent words.

Nonassertive interpretations can be divided into four groups. Statements about God have been interpreted as

(1) expressions of feelings of various sorts; (2) symbolic presentations of a variety of vital aspects of experience, from natural facts to moral ideals; (3) integral elements in ritualistic worship; (4) a unique kind of “mythical” or “symbolic” expression, not reducible to any other use of language.

EXPRESSIONS OF FEELING. Theological utterances have been interpreted as expressions of feelings that arise in connection with religious belief and activity. Thus we might think of “God made the heavens and the earth” as an expression of the sense of awe and mystery evoked by grandeur of nature; of “God has predestined every man to salvation or damnation” as an expression of a pervasive sense of helplessness; and of “God watches over the affairs of men” as an expression of a sense of peace, security, at-homeness in the world. This is “poetic” expression rather than expression by expletives. It is like expressing a sense of futility by saying “life’s a walking shadow” rather than like expressing futility by saying “Ah, me.” That is, the feeling is expressed by depicting a situation that might naturally evoke it; a sense of security, for instance, is evoked by some powerful person looking after one.

SYMBOLIC PRESENTATIONS. Symbolic interpretations of religious doctrines have been common for a long time. The story of Noah and the Flood has been regarded by many Christian thinkers not as an account of actual historical occurrences, but rather as a symbolic way of presenting certain religiously important points—that God will punish the wicked, but will also, under certain conditions, show mercy. Many of the traditional ways of speaking about God have to be taken as symbolic. God cannot literally be a shepherd or a rock. The shepherd functions as a symbol of providence and the rock as a symbol for God’s role as a refuge and protection in time of trouble. A symbol in this sense is some (relatively) concrete object, situation, or activity that can be taken to stand for the ultimate object of discourse through some kind of association, usually on the basis of similarity. We speak symbolically when what we literally refer to is something that functions as a symbol.

In the traditional use of symbolic interpretation it is, necessarily, only a part of theological discourse that is taken as symbolic. For if we are to hold that the symbolic utterances are symbolizing facts about God, we will have to have some way of saying what those facts are; and we cannot make that specification in symbolic terms, on pain of an infinite regress. But we are now considering views according to which all theological discourse is symbolic, which means that if we are to say what is being

symbolized it will have to be something in the natural world that can be specified in nontheological terms. The most common version of such a view is that theological utterances are symbolic presentations of moral ideals, attitudes, or values. This position has been set forth most fully and persuasively by George Santayana, and in a more up-to-date form by R. B. Braithwaite. According to Santayana every religious doctrine involves two components: a kernel of moral or valuational insight, and a poetic or pictorial rendering of it. Thus the doctrine that the physical universe is the creation of a supremely good personal deity is a pictorial rendering of the insight that everything in the world is potentially usable for the enrichment of human life. The Christian story of the incarnation, sacrificial death, and resurrection of Jesus Christ is a way of making the point that self-sacrifice for others is of supreme moral value. It is worthwhile embodying these moral insights in theological doctrine because this vivid presentation, together with the systematic cultivation of feelings and attitudes that accompanies it, provides a more effective way of getting across the insights than would a bald statement.

The way in which interpretations of the first two kinds throw light on the theological use of predicates is analogous to the way in which one explicates the use of words in poetic metaphors. If we consider the metaphor in “sleep that knits up the raveled sleeve of care,” it is clear that “knit” is not used simply to refer to a certain kind of physical operation. This utterance has quite different kinds of implications from “she knit me a sweater,” in which *knit* does have its usual sense. In the metaphoric statement, *knit* is used in its usual sense to depict a certain kind of situation that, as a whole, is presented as an analogue of the effect of sleep on care. The only way of effectively getting at the function of the word *knit* is by seeing how the whole phrase “knits up the raveled sleeve” is used to say something indirectly about sleep.

In the first two of the four kinds of nonassertive interpretation we are examining, theological statements are essentially metaphors. And if they are correctly so regarded, we get nowhere if we extract the word *made* from the sentence “God made the heavens and the earth” and try to say what it means by itself. What we have to do is take the picture presented by the whole sentence and see how it functions as a way of expressing a feeling of security, or as a way of presenting the insight that everything in the world can be used to enrich human life.

RITUALISTIC INTERPRETATION. The ritualistic interpretation of theological discourse can best be introduced

by citing the reply of an intellectually sophisticated high-church Anglican to a question from an agnostic friend. The question was, “How can you go to church and say all those things in the creed?” The reply: “I don’t say them; I sing them.” In the view under consideration, the corporate practice of worship is the native soil from which talk about God springs. Talk about the attributes, doings, and intentions of a supernatural personal being has meaning as a part of the practice of worship and is puzzling only when it is separated from that context. If we think of an utterance like “God made the heavens and the earth” as the expression of a belief about the way things in fact originated and then wonder whether it is true or false, we will be at a loss. To understand it we have to put it back into the setting where it (or rather a second-person correlate, such as “Thou, who hast made the heavens and the earth”) does its work. In that setting, these words are not being used to explain anything, but to do something quite different.

Unfortunately, proponents of this view have never been very clear about what this “something different” is. The clearest suggestion they give is that the talk about God serves to provide an imaginative framework for the conduct of worship. It articulates one’s sense that something important is going on, and it helps to indicate the appropriateness of one response rather than another. In speaking of the sacrament of communion as the reenactment of the self-sacrifice of an omnipotent personal deity who took on human form, and in conceiving of it as a cleansing and renewing incorporation of the substance of such a deity, one provides for the activity a pictorial framework that records and nurtures the felt solemnity of the occasion and the attitudes and aspirations kindled by the ceremony. This position presupposes, contrary to the usual view, that ritual worship has an autonomous value, apart from any theological foundation. It is generally supposed that a given ritual has a point only if certain theological doctrines are objectively true. But in the ritualistic interpretation, theological doctrines are not regarded as statements about which questions of truth or falsity are properly raised. Since these doctrines depend for their significance on the ritual, it is supposed that the ritual has some intrinsic value in forming and giving expression to valuable sentiments, feelings, and attitudes.

MYTHS. Ernst Cassirer has developed the notion that the basis of religious discourse lies in a unique “symbolic form” that he terms “mythical.” He maintains that it is found in purest form in the myths of primitive peoples and is based on a way of perceiving and thinking about the world that is radically different from our accustomed

mode. In the “mythical consciousness” there is no sharp distinction between the subjective and the objective. No clear line is drawn between symbol and object, between wish and fulfillment, between perception and fantasy. Again, no sharp distinction is made between the object itself and the emotional reaction it evokes; emotional response is taken to be an integral part of the environment. As a result none of our familiar standards of truth or objectivity are applicable. What is most real is what arouses the greatest intensity of emotional response and, particularly, what is felt as most sacred. (The sacred-profane distinction is the fundamental contrast.) The mythical consciousness carries its own special organizations of space and time. For example, there is no distinction made between a position and what occupies it; every spatial position is endowed with a qualitative character and exerts influence as such.

It is the view of Cassirer, and of followers such as Susanne Langer, that sophisticated theology represents an uneasy compromise between mythical and scientific modes of thought, and as such cannot be understood without seeing how it has developed from its origins. It is basically a mythical view of the world, given a “secondary elaboration” in a vain attempt to make it acceptable to the rationalistic consciousness; judged by rationalistic standards it is not only groundless, but meaningless.

Mysticism. Philosophers and theologians in the mystical tradition have put forward versions of this fourth kind of interpretation that do not regard theology as a manifestation of cultural lag. To the mystic the only way to communicate with God is through mystical experience, and this experience reveals God to be an ineffable unity. He can be directly intuited in mystical experience, but since there are no distinctions within the absolute unity of his being, and since any statement we can make predicates of him one thing rather than another, for example, wisdom as distinguishable from power, no statement can be true of him. The most we can do in language is to direct our hearers to the mode of experience that constitutes the sole means of access. Proponents of this view sometimes speak of theological language as “symbolic,” but this differs from our second type of theory in that here there is no way to make explicit what it is that the theological utterances symbolize, and it is therefore questionable whether we should use the term *symbol*. A symbol is always a symbol of something. In fact it is difficult to make clear just what, on this view, religious utterances are supposed to be doing. They are said to “point to,” “adumbrate,” or “indicate” the ineffable divine reality, but all too often these expressions remain uninterpreted.

In recent years two interesting attempts have been made to develop this position further. W. T. Stace, in his book *Time and Eternity* (1952), considers the chief function of religious language to be the evocation of mystical experience, or faint echoes thereof. This seems at first to be a subjectivist account, with the deity omitted, but, as Stace correctly points out, it is an axiom in the mystical tradition that no difference can be found in mystical experience between subject and object, and on these grounds Stace refuses to make the distinction. Although Stace goes along with the mystical tradition in regarding mystical experience as ineffable, he departs from this official position to the extent of giving some indications of the aspects of this experience that different theological utterances evoke. “God is truth” evokes the sense of revelatoriness, “God is infinite” the sense of all-inclusiveness, “God is love” the blissful, rapturous character of the experience, and “God is one” the absolute unity of the experience and the sense of the dissolution of all distinctions.

Paul Tillich, although not squarely in the mystical tradition, is faced with similar problems in the interpretation of religious language. He holds that theological doctrines “symbolize” an ultimate reality, “being-itself,” about which nothing can be said literally except that it is metaphysically ultimate. In attempting to clarify the function of religious language, Tillich develops the notion that it is an expression of “ultimate concern,” a complex of devotion, commitment, and orientation, focused on something nonultimate—a human being, a nation, or a supernatural deity. Religious statements, which literally refer to such relatively concrete focuses of ultimate concern, express the sense of the sacredness such objects have as “manifestations” of being-itself. But just what it is for such an object to be taken as a “manifestation” or “symbol” of being-itself, Tillich never makes clear.

The basic weakness in these mythical and mystical interpretations is the failure to present any clear hypothesis concerning the function of religious language. Even Cassirer’s ideas on “mythical thought” have never been developed to the point of clarifying what contemporary religious believers mean when they talk about God. The other positions are more intelligible, and they all base themselves on important aspects of the use of language in religion. But it seems that each, by inflating its chosen aspect to sole authority, has killed the goose that lays the golden eggs. There is no doubt that in talking about God, religious people express feelings of various sorts, present moral ideals, and articulate what is going on in ritual. But it is not at all clear that they would be using this kind of

language if they were not convinced of the truth of the statements they make. Why should I express a feeling of security by saying “God made the heavens and the earth” unless I believe, or at least have some tendency to believe, that as a matter of objective fact the physical universe owes its existence to the creative activity of a supernatural personal deity? Still more, why should I take on the complex of attitudes and activities that goes along with this assertion unless I believe it to be true?

The statement-making function is the cornerstone on which all the other functions depend. And if one is convinced that theological statements are either false or meaningless and still wants to hold to traditional religious formulations, one may *propose* a reinterpretation of theological utterances as expressions of feeling or symbolizations of natural facts. But a proposal for adopting a certain interpretation must be distinguished from a claim that the proposed interpretation correctly reflects the way doctrines are commonly understood.

It would seem that talk about God is much more complex than is recognized by any of the existing theories. The brief discussion given above of empirically testable implications illustrates this point. Theological sentences perform a great many closely interrelated linguistic functions. In saying “God, who created the world, watches over the affairs of men,” the believer is committing himself to a certain general view of the ultimate basis of the world, giving voice to certain, perhaps very indefinitely specified, expectations as to how things will ultimately turn out, expressing a basic sense of security in life, committing himself to approach God in prayer and ritual in one way rather than another. And these functions are intimately dependent on each other. What is needed is a description of the relationships among these functions, one sufficiently complex to match the complexity of the subject matter.

Bibliography

St. Thomas Aquinas’s historically important discussion of the “analogical” character of theological terms is found in Question XIII of Part I of the *Summa Theologiae*. For further discussions in the Thomist tradition see Cajetan, *The Analogy of Names*, translated by E. A. Bushinski and H. J. Koren (Pittsburgh: Duquesne University, 1953), and E. L.

Mascall, *Existence and Analogy* (London, 1949). Recent discussions by practitioners of analytical philosophy are to be found in Antony Flew and Alasdair MacIntyre, eds., *New Essays in Philosophical Theology* (New York: Macmillan, 1964), and in Basil Mitchell, ed., *Faith and Logic* (London: Allen and Unwin, 1957). See also Alasdair MacIntyre, “The Logical Status of Religious Belief,” in *Metaphysical Beliefs* (London: SCM Press, 1957); John Wisdom, “Gods,” in *Essays in Logic and Language*, edited by Antony Flew, first series (Oxford, 1951); C. B. Martin, *Religious Belief* (Ithaca, NY: Cornell University Press, 1959); and I. T. Ramsey, *Religious Language* (London: SCM Press, 1957). Various kinds of symbolic interpretations of religious statements are presented in George Santayana, *Reason in Religion* (New York: Scribners, 1905); R. B. Braithwaite, *An Empiricist’s View of the Nature of Religious Belief* (Cambridge, U.K., 1955); W. M. Urban, *Language and Reality* (New York, 1939); Edwin Bevan, *Symbolism and Belief* (Boston: Beacon Press, 1957); and Philip Wheelwright, *The Burning Fountain* (Bloomington: Indiana University Press, 1954). Ernst Cassirer’s views on mythical language are set forth most completely in Vol. II of *Philosophie der symbolischen Formen*, 3 vols. (Berlin: Cassirer, 1923, 1925, 1929), translated as *The Philosophy of Symbolic Forms* by Ralph Manheim (New Haven, CT: Yale University Press, 1952, 1955, 1957); and in more concentrated form in *Sprache und Mythos* (Leipzig: Teubner, 1925), translated as *Language and Myth* by S. K. Langer (New York: Harper, 1946). For other versions of the view that religious language constitutes an autonomous mode of discourse, see W. T. Stace’s *Time and Eternity* (Princeton, NJ: Princeton University Press, 1952) and Paul Tillich’s *Systematic Theology* (Chicago: University of Chicago Press, 1951–1963) and *Dynamics of Faith* (New York: Harper, 1957).

William P. Alston (1967)

RELIGIOUS LANGUAGE [ADDENDUM]

Two significant contributions to recent discussions of religious language are offered by Janet Soskice and William P. Alston. In *Metaphor and Religious Language* (1985) Soskice offers as a working definition “metaphor is that figure of speech whereby we speak about one thing in terms which are seen to be suggestive of another” (p.15). The minimum unit in which a metaphor is established is semantic. A satisfactory theory of metaphors “should regard metaphors neither as a simple substitution for literal speech nor as strictly emotive. Metaphors should be treated as fully cognitive and capable of saying that which may be said in no other way. It should explain how metaphor gives us “two ideas for one,” yet do so without lapsing into a comparison theory” (p.44). Noncognitive accounts of metaphor are rejected because “we cannot conceive of emotive ‘import’ apart from a

cognitive content which elicits it” (p. 27). The “two ideas for one” feature involves a metaphor having a “unity of subject matter” that “draws upon two (or more) sets of associations, ... characteristically, by involving the consideration of a model or models” (p. 49). A model is “an object or a state of affairs ... viewed in terms of its resemblance, real or hypothetical, to some other object or state of affairs” (p. 100).

Models come in two types: paramorphic (the source and subject differ, as in billiard ball movement serving as a model for the properties of gases); or homeomorphic, where the subject is the source (e.g., a dummy used to teach lifesaving skills). Models, in both theology and science, are essential to theories because they carry their explanatory force. “The fertility of a theory lies in its ability to suggest possibilities of explanation which, while not inconsistent with, are more than simply the logical extensions of mathematical formulas ... this suggestive capacity ... constitutes the fruitfulness of a theory, and gives the theory the predictive nature which is its *raison d’être*” (p. 114). We do not describe God but point to God through effects, and beyond them to him. We refer without defining. “This is the fine edge at which negative theology and positive theology meet, for the apophatic insight that we say nothing of God, but only point to Him ... this separation of referring and defining is at the very heart of metaphorical speaking...” (p. 140).

Nothing in Soskice’s account of metaphor entails that language about God must be nonliteral. The claim *All language about God is metaphorical* is not metaphorical. The idea that no metaphor can be translated into or replaced by literal terms is false. Consider Soskice’s example of an expression of hope that a soldier will be pardoned eliciting, “That’s blowing on cold coals.” “There’s no chance of that” is a literal translation. “God is a rock” seems replaceable by “God is utterly reliable.” If it is not, this is a matter of the associations of “rock” in biblical and theistic literature being multiple. It does not follow that any of the things that “rock” suggests are nonliteral. It just suggests that there are a variety of possibilities, more perhaps than we can list, each of which may be perfectly expressible without remainder in literal fashion.

A basic assumption is that no literal description can be true of God. As is typical, we are referred to certain ideas: We cannot comprehend (know all there is to know) about God; descriptions of God based on religious experience are defeasible; certainty about claims concerning God is unattainable; and it is always possible that we will have to modify our concept of God. But there are an infinite number of truths concerning a golden retriever, see-

ing the golden is defeasible, certainty about it is unavailable, and we may have to revise our concept thereof. But it is not beyond literal description. Further, God can be misdescribed (e.g., “God is a cantaloupe”), which even the most deluded of empiricist positivists presumably will recognize as false. But then what, in principle, precludes God from being correctly described?

William P. Alston’s major essays concerning religious language are collected in *Divine Nature and Human Language* (1989). In “Irreducible Metaphors in Theology” he says that “in the typical metaphorical statement the speaker is ‘building on’ the relevant meaning of the predicate term in two ways ... he is presenting the thing to which the term literally applies as a model of the subject [and] ... he has in mind one or more resemblances between model and subject and he abstracts from these resemblances what he means to be attributing to the subject” (1989, p. 23). The resemblance may be either general or specific. Everything resembles everything else in some way. Any metaphor based on this fact corresponds to a literal way of expressing the similarity. Regarding metaphors intended to express truths, he writes: “Though irreducible metaphors seem to promise a way of combining the denial of predication in theology with the preservation of significant theological truth claims, this fair promise dissipates on scrutiny like mist before the morning sun. Either the panmetaphoricist abandons the aspiration to significant truth claims or he revokes the ban on literal predication” (p. 37).

“Can We Speak Literally of God?” considers predicates that apply to personal agents (“P-predicates”) in their application to God. These include mental and action predicates. These have been understood on a private paradigm model (one knows what “depression” means by being depressed) and functionally (“being depressed” refers to a state that functions efficaciously in a causal system to yield a distinctive range of behavior). The idea of basic actions that involve no bodily movements, and of nonbasic actions that involve only mental actions that bring about effects, are both intelligible and applicable to incorporeal beings. “Literal” does not mean “empirical.”

“Functionalism and Theological Language” and “Divine and Human Action” consider functional accounts of mental concepts to argue that these concepts can apply to God. We can “form the conception of a being (a ‘system’) in which some factors depend on their relations to others for being what they are, even though there are no temporally successive processes for formation of any subjection to laws. More specifically, we are to think

of God as realizing a complex structure of attitudes, knowledge, tendencies, executive intentions, and volitions in the ‘eternal now’ ...” (p. 99). The stability of this system is to be understood, not by way of there being laws that hold regarding it, but by way of essential properties of the system. But this gives us only a description of God as a system of items that bear various dependence or causal relationships, not of a personal agent. Insofar as the relevant concepts are strictly functionalist, they do not entail even consciousness. When we turn to religious discourse about God, the functionalist account is not nearly enough: “For the religious life, we need to go beyond that in ways that launch us into the still not sufficiently charted seas of the figurative and the symbolic” (p. 103).

“Referring to God” distinguishes between direct reference and reference by description. Reference by description offers a description that is true only of the referent; direct reference names an object of one’s experience. Direct reference to God can occur only if someone experiences God (Alston takes it that some people do). Others who do not themselves experience God can then refer to the being that others have referred to; reference thus spreads throughout a religious community. Direct reference is more basic than descriptive, because if one refers to a being both descriptively and directly, and one learns that the description is false of the being directly referred to, it is the latter that determines what was the actual object of reference. Nonetheless, Alston admits that “reference could always take place via a description” (p. 107). A consequence is that it is possible that someone who thinks of God as an omnipotent, omniscient spirit, and one who thinks of God as an impersonal force, may refer to the same being. Alston says that it may be that both are “worshiping the one true God” (p. 116). If so, worship does not require much by way of actual knowledge of God.

There was never any reason to think that a causal theory of reference wedded to a functionalist account of P-predicates would yield significantly positive results regarding description of God. It seems fair to say that in spite of the sophisticated and helpful discussions provided by Soskice and Alston, accounts of religious language that are philosophically articulate and allow for seriously realistic accounts in theology remain more matters on the agenda than they are accomplishments of current work in the field.

Keith E. Yandell (2005)

RELIGIOUS PLURALISM

The fact that there is a plurality of religions is significant in different ways from different points of view. From a skeptical point of view their different and often incompatible beliefs confirm the understanding of religion as delusion. Thus, Bertrand Russell wrote that “It is evident as a matter of logic that, since [the great religions of the world] disagree, not more than one of them can be true” (1957, xi). From the point of view of an exclusive and unqualified commitment to any one religion the fact of religious plurality is readily coped with by holding that all religions other than one’s own are false, or false insofar as their belief systems differ from one’s own. But from a point of view that sees religion as a worldwide phenomenon that is not to be dismissed in toto as delusion but as the human response to a divine/transcendent/ultimate reality, the fact of plurality poses a major philosophical problem. On the one hand, the “great world religions” seem—to many impartial observers, at any rate—to affect human life for both good and ill to more or less the same extent. But on the other hand their respective belief systems, although having important similarities, also include starkly incompatible elements. According to some the Real (a term at home in the Judeo-Christian tradition and corresponding to the Sanskrit *sat* and the Arabic *al-Haqq*) is personal but according to others not personal. And within each group of religions there are wide differences. Is the ultimate Person the Christian Trinity or the Qur’anic Allah, or the Adonai of Judaism, or Vishnu, or Shiva? Is the nonpersonal Ultimate the Brahman of advaitic Hinduism, or the Dao, or the Dharmakaya or Void or Nirvāṇa of the Buddhist traditions? And how could the Real be all of these at once? The logic of religious difference here is in fact very complex, as is shown by William Christian’s analysis (1987).

The problem is particularly acute for a major form of religious apologetic that became prominent in the 1980s and 1990s. This holds that the basic empiricist principle that it is rational, in the absence of specific overriding

considerations, to base beliefs on experience should be applied impartially to all forms of putatively cognitive experience, including religious experience—unless, again, there are specific overriding considerations to the contrary. This has been argued directly by William Alston (1991) and others and indirectly by Alvin Plantinga (in Plantinga and Wolterstorff 1983), whose defense of the rationality of holding “properly basic” religious beliefs presupposes religious experience as their ground.

Most of the philosophers who employ this kind of apologetic have applied it only to specifically Christian beliefs. But it is evident that precisely the same argument is available for the belief systems of other religions. If Christian religious experience renders it epistemically justifiable (subject to the possibility of specific reasons to the contrary) to hold Christian beliefs, then Buddhist religious experience renders it epistemically justifiable, with the same qualification, to hold Buddhist beliefs, Muslim religious experience to hold Muslim beliefs, and so on. Thus, anyone who maintains that the Christian belief system is true, but that the belief systems of Buddhists, Muslims, and so on are false insofar as they differ from it, has implicitly reversed the original apologetic and is presenting Christian religious experience as the sole exception to the general rule that religious experience gives rise to false beliefs!

Alston, recognizing the challenge posed by the fact of religious diversity to the experiential apologetic, has responded by saying that in this situation it is proper for the Christian to continue within her own belief system, despite the existence of other equally well-justified alternatives, while, however, she seeks “a way to show in a non-circular way which of the contenders is correct” (1991, p. 278).

An alternative use of the experiential apologetic rejects the assumption that only one of the different religious belief systems can be true. This approach (Hick 1989) distinguishes between, on the one hand, the ultimate religious reality, the Real, beyond the scope of our (other than purely formal) human conceptualities, and, on the other hand, the range of ways in which that reality is humanly conceived, and therefore humanly experienced, and therefore humanly responded to within the different religiocultural ways of being human. The epistemology operating here is one that, in the Kantian tradition, recognizes an important contribution by the perceiver to the form a reality is perceived to have. As Thomas Aquinas wrote, “Things known are in the knower according to the mode of the knower” (*Summa Theologiae*, II/II, 1, 2). And in religious knowing the mode of the

knower differs from religion to religion. From this point of view the fact of religious diversity does not constitute a challenge to the experiential apologetic but rather a series of examples of its valid application.

Other philosophical responses to the fact of religious plurality, not specifically related to the experiential apologetic, include the “perennial philosophy” (e.g. Schuon 1975, Smith 1976), which distinguishes between the essence (or esoteric core) of religion and its accidental (or exoteric) historical forms. In their esoteric essence all the great traditions converge in a transcendental unity, the Absolute Unity that is called God. Experientially, this sees the mystics of the different religions as participating in an identical experience, although they articulate it in the different ways provided by their traditions. This view is opposed by those (e.g., Katz 1978) who hold that all experience is concept laden and that mystical experience accordingly takes different forms within the different traditions.

There is also the view of John Cobb (in Kellenberger 1993) that the religions are directed toward different ultimates, particularly the personal reality worshiped in the theistic religions and the nonpersonal process of the universe experienced in Buddhism. Yet other constructive suggestions include those of Joseph Runzo (1986), James Kellenberger (1989), and the authors included in the symposium *Inter-Religious Models and Criteria* (Kellenberger 1993).

RENAISSANCE

“Renaissance” is the term customarily employed to designate a cultural movement that began in Italy in the middle of the fourteenth century and spread throughout the rest of Europe. Although the term is well established in the writings of historians, its usefulness has been challenged. Indeed, there has grown up around the concept of the Renaissance an extensive controversy that sometimes threatens completely to divert the attention of scholars from the historical facts. In part, this controversy is simply an acute form of the general problem of periodization in history. The concept of the Renaissance, however, arouses particularly strong opposition because it involves a disparagement of the preceding period, the Middle Ages (*medium aevum*), from which culture presumably had to be awakened.

The idea of a rebirth of literature or of the arts originated in the period itself. Petrarch in the fourteenth century hoped to see an awakening of culture, and many later writers expressed their conviction that they were actually witnessing such an awakening in their own time. Latin was generally the language used by cultivated men to discuss such matters, but no single Latin term or phrase became the standard name for the whole cultural epoch. One of the earliest historians of philosophy in the modern sense, Johann Jakob Brucker, in 1743 referred to the Renaissance only as the “restoration of letters” (*restauratio literarum*), and wrote of the “recovery of philosophy” (*restitutio philosophiae*): Even in an earlier German work he used such Latin phrases. Scholars who wrote in Latin

never used *rinascencia* as the name for the cultural epoch as a whole. It was the French word *renaissance* that finally acquired this status and was then adopted or adapted into other languages. During the seventeenth century, and fitfully before, French scholars used the phrase *renaissance des lettres* for the humanists’ *restitutio bonarum literarum*, taking over in the process the humanist periodization of history. Other writers translated the Latin phrase or phrases into their own vernacular: Edward Gibbon (1787) spoke of the “restoration of the Greek letters in Italy,” while Heinrich Ritter, in his history of philosophy (1850), remarked that the *Wiederherstellung der Wissenschaften* derived its name from philology.

Various French authors used the term *renaissance* in titles of their works before Jules Michelet devoted one of his volumes on sixteenth-century France to *la Renaissance* (1855). However, Michelet gave only the sketchiest characterization of the period, and hardly deserves to be credited (if indeed any one person can be) with having “invented” the concept of the Renaissance. Michelet did coin one memorable phrase: He remarked that two things especially distinguished the Renaissance from previous periods—“the discovery of the world, the discovery of man.” This phrase was also used by the Swiss cultural historian Jakob Burckhardt for the title of a chapter in his famous work, *The Culture of the Renaissance in Italy* (1860). At his hands, the concept of the Renaissance received what was to become its classic formulation; all subsequent discussion of the concept invariably focuses upon Burckhardt’s description of the essential features of life during the Renaissance. Burckhardt, taking the term in its narrow sense of a literary revival of antiquity, conceded that there had been earlier “renaissances” in Europe; but he insisted that a renaissance in this sense would never have conquered the Western world had it not been united with the “already-existing spirit of the Italian people” (*italienischen Volksgeist*). Not until the time of Petrarch, so Burckhardt held, did the European spirit awake from the slumber of the Middle Ages, when the world and man lay “undiscovered.”

The relation of the Renaissance to the era that preceded it has been much studied because defenders of medieval culture quickly came to the rescue of their period, stressing its continuity with, or even its superiority to, the Renaissance. However, little has been done to clarify the relation of the Renaissance to the Enlightenment. This is rather surprising, for there was an issue that ran straight through the thought of both these eras: “Can we modern men hope to equal or even excel the achievements of antiquity?” This issue is known to literary histo-

rians as the “quarrel of the ancients and moderns.” We think of Bernard Le Bovier de Fontenelle in the seventeenth century as the main champion of the moderns, who had science and truth on their side, as against those writers, with their inflexible rules, who favored the ancients. However, much the same attitude as Fontenelle’s is found in the *De Disciplinis* of the Renaissance humanist Juan Luis Vives, who wrote in the early sixteenth century. The Renaissance itself had championed the moderns even before modern science had arisen to prove their case. Renaissance confidence in men’s powers was based on art and literature rather than on science, but it was strong nevertheless. Men could respect classical excellence and yet strive to outdo the ancients in every field, including vernacular literature.

CHRONOLOGICAL LIMITS

Various events have been taken as marking the beginning of the Renaissance: the crowning of Petrarch as poet laureate of Rome in 1341; the short-lived triumph of Cola di Rienzi in setting up a republican Rome in 1347, an attempt to revive Rome’s former greatness; the arrival in Italy of Greek *émigrés* (which actually antedated by a few years the much publicized fall of Constantinople in 1453); the opening up of new trade routes to the East. Each choice represents the selection of a particular field as central in the history of the period: art, architecture, religion, politics, economics, trade, or learning. In certain fields it is hard to maintain any sharp break between conditions in, let us say, 1300 and those in 1350. However, few students of the history of art or of literature are prepared to deny completely the start of new trends in the fourteenth century (at least in Italy). In literature, Petrarch’s enthusiasm for Greek antiquity must surely be accepted as inaugurating, in the eyes of men in the fourteenth century, a fresh start. In painting, there is little hesitation about ascribing a similar place to Petrarch’s contemporary, Giotto; this ascription dates from the earliest attempt at a history of art, that of Giorgio Vasari (1550). No such figures can plausibly be singled out to mark new beginnings in economic or political history.

Difficulties also surround the choice of an event to mark the end of the Renaissance: the sacking of Rome in 1527, the hardening of the Counter-Reformation via the Council of Trent in 1545, the burning of Giordano Bruno in 1600, or Galileo Galilei’s setting of experimental physics on its true path around 1600—any of these might be selected. Once again, however, a periodization that is useful in one field may prove useless in another field. Generally speaking, the era from 1350 to 1600 will

include most of the developments commonly dealt with under the heading “Renaissance.”

GEOGRAPHICAL LIMITS

The shifting locale of the Renaissance presents problems similar to those of its chronological limits. Burckhardt’s description focused exclusively on Italy; he implied that the Renaissance, after it had been taken over by the Italian *Volksgeist*, moved on to the rest of Europe. The movement to France is usually said to have resulted from the French invasion of Italy in 1515, which gave the French nobility their first glimpse of the glories of the Italian Renaissance. No comparable event can be singled out for the bringing of the Italian Renaissance to England, unless it be the return from Italy to their native land of the classical scholars William Grocyn, Thomas Linacre, and John Colet in the last decade of the fifteenth century, or perhaps Desiderius Erasmus’s arrival there about the same time. Clearly England did enjoy a renaissance, but it is not easy to fix its dates: English literary historians prefer to discuss the Elizabethan age or the age of the Tudors, thus sidestepping the question of the relation of the English Renaissance to that of the Continent. Still less clear is the coming of the Renaissance to the German lands: German historians treat the sixteenth century as the “time of the Reformation,” and tend to discuss the Renaissance chiefly in terms of its impact upon individual reformers.

The Renaissance is sometimes called the “age of adventure.” It is not at all clear, however, that the spirit behind men’s daring and adventurous actions was entirely new: The two chief incentives toward voyages of discovery, for instance, were commercial acquisitiveness and religious zeal—attitudes by no means foreign to medieval men. It was the shutting off of Venetian trade routes through the Mediterranean by the Turks that forced Europeans to search for new routes to the East, not a new desire for scientific knowledge of geography. The Spanish *conquistadores* may have thirsted for glory, but such a thirst was characteristic of medieval knights as well as of Renaissance humanists. The motives of the Franciscan missionaries were clearly religious and medieval in spirit. Moreover, in the field of domestic trade, the resurgence of economic activity in the fifteenth century that formed the basis for the cultural developments of the Renaissance was less a matter of suddenly effective acquisitiveness than of normal recovery from the slump brought about by the Black Death in 1348.

THE NEW LEARNING

Historians may without hesitation ascribe a rebirth of classical knowledge to the Renaissance period. The discovery of old manuscripts and the invention of printing combined to make the heritage of ancient Greece and Rome available to a far wider audience. The humanists of the fourteenth and fifteenth centuries discovered and preserved many ancient texts that had been neglected for centuries. Of these perhaps the most significant from a philosophical point of view was Lucretius's *De Rerum Natura*, but many other newly discovered texts helped to enrich men's general familiarity with antiquity and to present in full view the setting in which Greek and Roman philosophy originated.

The collecting of manuscripts could be indulged in only by noblemen or well-to-do scholars, but the invention of printing made possible a broader social base for intellectual interests. With the production of vast numbers of newly discovered texts, self-education became a real possibility, as did institutional education on a broad scale. Peter Ramus in France and Philipp Melanchthon in Germany urged the educating of the people, chiefly with the idea of promoting intelligent Christian piety.

SCIENCE

Developments in technology and science indirectly provided material for philosophical reflection. The increased use of firearms and cannon in war, for example, made necessary the mathematical study of ballistics; and the scientific work of Benedetti and Galileo drew upon the practical experience of foundries and arsenals. However, Renaissance philosophy of science still took its cue largely from Aristotle: Francis Bacon, dissatisfied with Aristotelian logic and methodology of science, found a replacement not in the actual practices of mechanics and craftsmen but in the rhetorical method derived from Aristotle and applied to the questioning of Nature.

The most spectacular and far-reaching scientific development during the Renaissance was the heliocentric theory advanced by Nicolas Copernicus, who found hints about Pythagorean cosmology in ancient works. The Copernican theory was surely the most significant revolution ever to take place in science. Far less conspicuous, but still important, were the developments in pure and applied mathematics. Modern notation (such as the use of the "equals" sign) began to be adopted, bringing with it the possibility of greater attention to logical form.

SOCIAL VALUES

There have been many attempts, beginning with Michelet and Burckhardt, to capture *the* mind or spirit of Renaissance man. All such attempts seem doomed to failure, for they are bound to oversimplify complex social facts. We may, however, single out four sets of social ideals that were characteristic of various groups during the Renaissance.

The ideals of the feudal nobility, medieval in origin, persisted through the Renaissance among the ruling class, although they underwent considerable refinement. The rude military virtues of camp and field gave way to the graces of the court, which were set forth most admirably in Baldassare Castiglione's book *The Courtier* (1528), one of the most influential treatises on manners ever written. In Castiglione's ideal courtier we may recognize the ancestor of our "gentleman." Works of this sort are presumably also the source of the "universal man," a concept closely associated in modern minds with the Renaissance. In the heroic life idealized by the feudal tradition, love of glory and concern for one's reputation were strong social motives. The humanists' thirst for glory, which Burckhardt emphasized, merely continues this concern but applies it to the achievements of a nonwarrior class, the "knights of the pen." The urban middle class chose, as usual, to emulate the style of life of their superiors: the modern gospel of work as a *raison d'être*, shaping the whole of life, hardly existed during the Renaissance. Few social theorists extolled the virtues of commercial activity until Martin Luther stressed the sanctity of all callings, provided they benefited one's fellow men.

Religion provided the second set of ideals, which centered upon moral salvation and involved a willingness to relinquish the world and all its goods. This mood, exacerbated in some individuals by the terror of imminent death or of eternal damnation, continued unabated throughout the Renaissance; and the entire Reformation movement has been called the "last great wave of medieval mysticism." Although such a religious concern is usually associated by modern secular critics with contempt for this world and with pessimism, it is equally compatible with a cheerful resignation in the face of unavoidable misfortunes and gratefulness for such morally harmless pleasures as life affords. A genuine tension often resulted from the opposing pulls of these religious values and of secular attitudes and this-worldliness: Aristotelian philosophers as well as humanists felt this tension during the Renaissance.

A third set of ideals, that of the ancient sage (Platonic or Stoic), was consciously adopted by Renaissance

humanists as an adjunct to Christian exhortation, for many of them felt that Christians could learn much from pagan expounders of virtue. Rarely, if ever, did a humanist attempt to replace the Christian ideal altogether: Burckhardt undoubtedly overstressed the “paganism” of the humanists.

Finally, there was the ideal of a return to nature, a flight from the complexities of sophisticated urban life to pastoral pleasures. This theme has ancient antecedents in the poetry of Theocritus and Vergil, but it emerges into new prominence with Petrarch, who also stressed the benefits of solitude. Passive delight in the beauties of nature can hardly ever be totally lacking in human beings, of course, but during the Renaissance we find an interest in such activities as gardening, the collecting of strange plants and animals, and strolling through woods and fields. Petrarch’s famous excursion to the summit of Mont Ventoux turned into an occasion for Christian self-reproach, to be sure, but his letters also abound in references to his gardening and to lone promenades in the countryside near Vaucluse.

HUMANISM

A major role in the culture of the Renaissance was played by the humanists. All sorts of people call themselves “humanists” today, but in the early days of the Renaissance the name had a clear occupational meaning. During the fourteenth century, the traditional subjects of grammar, rhetoric, and poetry had begun to be called, after a phrase of Cicero, the *studio humanitatis*. The term *umanista* was coined (on the analogy of *artista*, also a product of university slang) to designate a teacher of these subjects in Italian universities. Such studies were by no means new in the fourteenth century; in fact, the humanists were the heirs of a less ambitious but old and respectable medieval profession, that of the *dictator* or teacher of the art of letter-writing (*ars dictaminis*). The Renaissance teachers of “humanities” placed a greater emphasis on ancient models than had the *dictatores*, but their teaching had much the same; objective. Their students often became official letter-writers or speech-makers for popes and princes. Coluccio Salutati and Leonardo Bruni, two of the most influential humanists of the fifteenth century, were chancellors of Florence. The study of Greek philosophy owes much to these two men.

Renaissance humanists did not propound a distinct philosophy but took over from Cicero and Aulus Gellius the ancient ideal of a civilized and urbane way of life that could be formed through acquaintance with Greek literature. With such a program in mind, the humanists began

to concern themselves with moral and political philosophy, and this brought them into conflict with the philosophers who taught ethics or politics in the universities. The humanists regarded the Aristotelian Schoolmen as derelict in the performance of their duties, since their teaching (so the humanists claimed) made no differences in the lives of students. The scholastic teachers, in return, regarded the humanists as dilettantes and upstarts, meddling in subjects beyond their depth. The feud of humanists with philosophers began with Petrarch’s invective against the secular Aristotelians, the so-called Averroists of his day, and continued through the seventeenth century.

We still tend to see Renaissance Aristotelianism (and medieval Scholasticism as well) through the eyes of these Renaissance humanists. Their bias has crept into most histories of philosophy, largely because the first writers of histories of philosophy shared some of the humanist attitudes. One such early historian was Brucker, whose *Critical History of Philosophy* (1742–1744) has already been mentioned. Brucker presented the Renaissance as a time when human thought emerged slowly into the light (a standard metaphor) from the tiresome labyrinths of medieval Scholasticism. He divided his treatment into various sections, dealing with schools of Greek philosophy that were “restored” during the Renaissance. In spite of his scorn for “more recent Aristotelian-scholastic philosophers,” Brucker had great respect for the philosophers who followed the “genuine philosophy of Aristotle”: Pietro Pomponazzi, Simon Porta, Jacopo Zabarella, and others. Few modern historians of philosophy pay much attention to these writers. They do, however, characteristically devote lengthy sections to Paracelsus, Jakob Boehme, Robert Fludd, and other “theosophers.” According to Brucker, these theosophers “condemn all use of reason in understanding the nature of things,” and hence do not belong to the history of philosophy; he includes them only because they have commented incidentally on philosophical matters.

Whatever his own philosophical competence may have been, Brucker had one clear advantage over most later historians: He had actually read the Renaissance writers he discussed. Much of Renaissance philosophy still awaits reevaluation based upon such actual reading of texts.

The general framework of Brucker’s treatment of Renaissance philosophy remains a useful way of dealing with most of the thought of the period. The various sects of Greek philosophy were indeed “reborn” during the Renaissance; few of them escaped some sort of revival.

There was even what might be called a genuine rebirth of Aristotle, if we mean by this what Brucker probably meant: an Aristotelianism based directly upon the Greek texts rather than upon Latin or Arabic commentators.

ARISTOTELIANISM. It cannot be too strongly emphasized that the main stream of philosophical inquiry during the Renaissance continued to be Aristotelian. The terms employed in philosophical discussion, the problems posed, and the characteristic solutions remain, in basic outline, Aristotelian. Almost all Renaissance philosophers show the influence of their Aristotelian school training, even when they are trying most strenuously to break the shackles of that tradition. The technical terms of philosophy (such as *propositio*, *entitas*, *realis*, *materia*, *forma*, *essentia* and many others) originated or became naturalized in the Aristotelian school-tradition, and persisted even in the writings of the most daring innovators, such as Bruno. The Aristotelian tradition, for reasons already in part suggested, remains the least known and most maligned of all Renaissance schools. Elements of the critical spirit of later medieval philosophy (Scotist and Ockhamist) formed part of the school philosophy of the Spaniard Francisco Suárez and of the Scotsman John Major.

PLATONISM. Platonism took on new life during the Renaissance, after having been known for centuries chiefly through Aristotle's attacks on it. There was more acquaintance with Plato during the medieval period than is generally recognized, but it is still true that Marsilio Ficino's translations into Latin (first published in 1484) gave the main impetus to the spread of Plato's doctrines. Later editions of Plato often contained Ficino's translations of Proclus and Porphyry, together with his own commentaries, which were strongly colored by his Neoplatonism. Hence, the Platonism that emerged during the Renaissance cannot be distinguished easily from Neoplatonism, for it tends to be otherworldly and religious in tone. The cultural influence of Florentine Platonism emanated from the famous academy founded by Ficino in direct imitation of Plato's school. The society that grouped itself around Ficino aimed at moral improvement and resembled in character certain lay religious societies common in Italy at that time. The whole movement of natural religion was set in motion by Florentine Platonism, as was the renewed study of Pauline theology by such men as John Colet.

Florentine Platonism is well known, by name at least, to most students of the Renaissance. Much less well known is a tradition of reconciling Plato with Aristotle,

which also found expression during the period. Byzantine scholars had brought with them to Italy an old battle over the superiority of Plato or Aristotle. During the late Renaissance this battle resolved itself into a truce, with many books written to show that Plato and Aristotle agreed on fundamentals and differed only on words or nonessentials.

STOICISM. Only a few late Renaissance thinkers, such as Justus Lipsius and Guillaume du Vair, committed themselves explicitly to Stoicism, but the influence of Stoic philosophy may be seen at work directly and indirectly (largely via Cicero, Seneca, and the Greek commentators on Aristotle) even during the early Renaissance. Pomponazzi's rigorous moral doctrine, for example, is strongly tinged with Stoic attitudes.

EPICUREANISM. Rejected with horror by medieval thinkers, who saw him through the eyes of the Church Fathers, Epicurus began to be more sympathetically known as a result of humanist activity in the fifteenth century. Previous to this time, anyone who believed that the soul perished with the body was called an Epicurean, whether he held to any other Epicurean tenet or not. Now it was no longer possible to apply this label so casually. Lucretius's great poem won immediate favor because of its sturdy poetic qualities, but, until Pierre Gassendi in the seventeenth century, no one adopted the system of Epicurus in its entirety. Nevertheless, Epicurean influence prior to Gassendi's time did foster a climate less hostile to the concepts of pleasure and utility.

SKEPTICISM. The direct influence of philosophical skepticism in a technical sense began with the first publication of Sextus Empiricus in 1562, from which time skepticism exercised an important influence upon European thought and literature. The religious factionalism or warfare of the sixteenth century had brought about a widespread distrust of dogmatism and fanaticism on the part of such sophisticated minds as Erasmus and Michel Eyquem de Montaigne, whose writings may have contributed to the growth of that spirit of toleration usually associated with the Enlightenment.

THE OCCULT TRADITION. The Renaissance was immensely receptive (perhaps more so than the Middle Ages) to occult and secret lore of all kinds, especially if it claimed to come from the most ancient times and to incorporate the wisdom of the Egyptians, Chaldeans, and Hebrews. When the fashion for reviving ancient thought was at its height, the spurious treatises of "thrice-great

Hermes,” the so-called Hermetic writings, enjoyed great prestige and blended easily with various other secret teachings, such as that of the Jewish Kabbalah.

Toward the end of the Renaissance, the vogue for reviving past philosophies began to subside: Instead, there began to appear “new” philosophies and “new” systems of thought proudly announced as such, for instance, the *Nova de Universis Philosophia* offered by Francesco Patrizzi or the *Great Instauration* (explicitly opposed to a “restoration”) of Francis Bacon. However, most of these efforts at original creation clearly bear the stamp of some ancient sect or sects of philosophy. Even Nicholas of Cusa, the most original systematic mind of the Renaissance, could be called (and indeed once called himself) a Pythagorean. Philosophers hardly ever make a complete break with the past, even when they most loudly claim to be doing so. The great merit of the Renaissance was that thinkers learned what they could from the school of Athens and brought what they learned to bear with fresh vigor upon the problems of human life.

CARDANO

No individual completely typifies his age, yet it may be useful to focus for a moment on the way in which the various philosophical traditions converged in a single person. As a case history of this sort, we may take the thought of Girolamo Cardano (1501–1576), an Italian medical man and mathematician. Cardano lived in the late, mature stage of the Renaissance, when the dialogues of Plato and the works of Aristotle were known in their entirety, as were Galen and Hippocrates. The Greek commentators on Aristotle were just being recovered and translated. These works were well known at the universities where Cardano studied: Pavia, a stronghold of humanist learning, and Padua, a center of science and medicine. At Padua the biological and logical aspects of Aristotle’s thought were stressed in connection with medical training. Cardano studied under Joannes Montescio, a Spaniard, whom he mentions in his writings. There were quite a few such Iberian philosophers studying and teaching in Italy at this time. Aristotelian philosophy was clearly a common European heritage and knew no national boundaries.

A considerable number of Renaissance philosophers were, like Cardano, medical men, and of these quite a few dabbled in mathematics (Galen had urged them to study mathematics for the sake of the training it gave them in sound demonstration). Cardano was, of course, far more successful than most in mathematics: No matter what the true story of his relations with Niccolò Tartaglia may be,

there can be no questioning of Cardano’s grasp of algebra, as shown by his solution of cubic equations. Cardano wrote works on medicine, astrology, and mathematics, but his philosophical reputation must rest primarily on two works in natural philosophy: *De Subtilitate Libri XXI* (On subtlety; 1550) and its sequel, *De Rerum Varietate* (On the variety of things; 1557). *De Subtilitate* attempted a total reconstruction of natural philosophy.

Since other philosophers of the period were inspired to embark on similar projects, it is clear that there was widespread dissatisfaction with Aristotle’s philosophy of nature even before the attacks of Galileo or René Descartes. Aristotle’s physical system was to be threatened dramatically by Copernican heliocentrism, which upset the conceptual scheme on which Aristotle’s analysis of motion was based. This threat was not explicitly posed, however, until the next century, with Galileo’s *Two Chief World Systems*. A Renaissance philosopher such as Cardano did not specifically base his criticisms of Aristotle on the findings of Copernicus or Vesalius: Instead, he reproached Aristotle in a general way for having built up “certain general propositions that experiment teaches to be false.” Cardano presumably intended to remedy this defect, although it must be confessed that his empiricism is not worked out in philosophical detail. This observation would apply with equal force to most Renaissance nature philosophers, few of whom gave more than perfunctory attention to epistemology.

In developing his own system, Cardano started out by taking as his central category something called “subtlety,” which he described as “a certain reason by which sensibilia are with difficulty comprehended by the sense, and intelligibilia by the intellect.” Cardano soon abandons this unpromising concept in favor of a revised Aristotelian terminology in which matter, form, soul, principle, and element play roles somewhat analogous to those they play in Aristotle’s philosophy. For example, Cardano retains the notion of elements but reduces their number from the traditional Aristotelian four to three by eliminating fire, which he classifies as an “accident.” Matter and motion—those central concepts of mechanism—are regarded by Cardano as principles, but they must share this status with form, place, and soul. The last addition puts Cardano into the class of hylozoists, those who believe that all matter is somehow animated, a rather characteristic Renaissance doctrine borrowed largely from Neoplatonism.

Cardano’s writings must have appealed to his Renaissance readers: They are lively, detailed, and full of medical and factual information and misinformation. His style

contrasts sharply with the dry, logically structured argument of the medievals, which can still be found early in the century in the work of a man such as John Major. Cardano obviously delighted in mathematics and in machinery, in this respect, at least, anticipating Galileo in the generation that followed. The amount of superstitious nonsense incorporated in Cardano's work, however, is still distressingly high, and one can easily understand the impatience of later figures such as Gassendi, Thomas Hobbes, and Galileo with their Renaissance predecessors. Cardano wrote a painfully candid autobiography, which appeared in Paris with an evaluation by the French writer Gabriel Naudé (1643). Naudé's judgment on Cardano's character is quite severe. This illustrates a general trend in scholarship: The information current today about many Renaissance thinkers, especially the Italians, comes to us by way of generally hostile French writers of the seventeenth century (Pierre Bayle is exceptional in his lack of polemical intent). If we approach Cardano with the distaste of a Naudé, for example, we too might be inclined to dismiss his work *On Consolation* (1542) as a piece of moralizing cant, when in fact a more humane scholar might consider it a noble document in the light of Cardano's wretched life. Or again, Cardano's passion for gambling could be presented as a despicable and mercenary motive for his interest in games of chance.

But a less censorious approach, such as that of Oystein Ore in his *Cardano, the Gambling Scholar* (Princeton, NJ, 1953), will give Cardano the credit he deserves for anticipating the modern conception of probability as the proportion of favorable outcomes to total possible outcomes. Finally, the mere fact that there was enough interest in Cardano's thought still lingering in seventeenth-century France to justify the publication of his entire work (*Opera Omnia*, 10 vols., Lyons, 1663), shows that Naudé's attitude was by no means universal. This comment could also be made of many other Renaissance philosophers who continued to be read in the seventeenth century, even if not all students of that century were as receptive to Renaissance thought as was Gottfried Wilhelm Leibniz.

See also Florentine Academy; Hermeticism; Humanism.

Bibliography

Everyone interested in the Renaissance should begin by reading two masterpieces of historical writing: Jacob Burckhardt, *Civilization of the Renaissance in Italy* (1st German ed., Basel, 1860), and Johan Huizinga, *The Waning of the Middle Ages* (1st Dutch ed., Haarlem, 1919), both available in various English editions. These works

complement each other: Huizinga deals with France and the Low Countries; Burckhardt deals only with Italy and apologizes for having even mentioned Rabelais. No works of comparable standing in cultural history exist for the Renaissance as it affected England, the German lands, or other European countries.

On the concept of the Renaissance, see Wallace K. Ferguson, *The Renaissance in Historical Thought* (Boston: Houghton Mifflin, 1948), and Franco Simone, *Il rinascimento francese* (Turin: Società Editrice Internazionale, 1961), which adds new evidence for the seventeenth century in France. Invaluable evidence is contained in Herbert Weisinger's articles, especially "The Self-Awareness of the Renaissance," in *Papers of the Michigan Academy of Science, Arts, and Letters* 29 (1944): 561–567. See also Augusto Campana, "The Origin of the Word 'Humanist,'" in *Journal of the Warburg and Courtauld Institutes* 9 (1946): 60–73, and Hans Baron, "The *Querelle* of the Ancients and the Moderns as a Problem for Renaissance Scholarship," in *Journal of the History of Ideas* 20 (1959): 3–22. See also Federico Chabod, "The Concept of the Renaissance," in *Machiavelli and the Renaissance* (New York: Harper Torchbooks, 1965).

For general historical background, Edward M. Hulme, *The Renaissance, the Protestant Revolution, and the Catholic Reformation in Continental Europe* (New York: Century, 1914), is convenient. Excellent summaries may be found in *The New Cambridge Modern History*, Vol. I, *The Renaissance, 1493–1520* (Cambridge, U.K.: Cambridge University Press, 1957).

On humanism, two older works are still basic: Georg Voigt, *Die Wiederbelebung des classischen Alterthums*, 2 vols., 3rd ed. (Berlin, 1893), and J. E. Sandys, *A History of Classical Scholarship*, 3 vols. (Cambridge, U.K.: Cambridge University Press, 1903–1938). All can profit from reading Erwin Panofsky, *Renaissance and Renascences in Western Art* (Stockholm: Almqvist and Wiksell, 1960).

Coming more particularly to philosophy, a useful guide is Paul O. Kristeller and J. H. Randall Jr., "The Study of the Philosophies of the Renaissance," in *Journal of the History of Ideas* 2 (1941): 449–496. Two leading mid-twentieth-century historians of Renaissance philosophy are Paul O. Kristeller and Eugenio Garin. Kristeller's major books are *The Classics and Renaissance Thought* (Cambridge, MA: Oberlin College by Harvard University Press, 1955), revised and enlarged in *Renaissance Thought* (New York, 1961); *Studies in Renaissance Thought and Letters* (Rome: Edizioni di Storia e Letteratura, 1956), which brings together many valuable articles; and *The Philosophy of Marsilio Ficino* (New York: Columbia University Press, 1943). Kristeller's work is solidly based on careful reading of the sources. Garin has dealt with philosophers of the Italian Renaissance extensively in his *La filosofia*, 2 vols. (Milan, 1947), and has compiled useful anthologies, including *Filosofi italiani del quattrocento* (Florence, 1942) and *Il rinascimento italiano* (Milan, 1941). An invaluable anthology, edited by Ernst Cassirer, Kristeller, and Randall, is *The Renaissance Philosophy of Man* (Chicago: University of Chicago Press, 1948).

For French thought during the Renaissance, see Augustin Renaudet, *Préréforme et humanisme à Paris pendant les premières guerres d'Italie (1494–1517)*, 2nd ed. (Paris: Librairie d'Argences, 1953). For Germany, see Peter Petersen, *Geschichte der Aristotelischen Philosophie im*

protestantischen Deutschland (Leipzig: Meiner, 1921), and Max Wundt, *Die deutsche Schulmetaphysik des 17. Jahrhunderts* (Tübingen, 1939). On Spain see Carlo Giacon, *La seconda scolastica*, 3 vols. (Milan: Fratelli Bocca, 1944–1950). On Italy, besides Garin's works, see Giuseppe Saitta, *Il pensiero italiano nell'umanesimo e nel rinascimento*, 3 vols., 2nd ed. (Florence: Sansoni, 1961), and Hans Baron, *The Crisis of the Early Italian Renaissance*, 2 vols. (Princeton, NJ: Princeton University Press, 1955). Important studies are those of Ernst Cassirer, especially *The Individual and the Cosmos in Renaissance Philosophy*, translated by Mario Domandi (New York: Harper, 1964).

The Renaissance is a favorite topic for symposia, and the results are sometimes useful: See Tinsley Helton, ed., *The Renaissance* (Madison: University of Wisconsin Press, 1961), with contributions by various authorities. Two specialized studies are Carlo Angelieri, *Il problema religiosa del rinascimento* (Florence, 1952), and Georg Weise, *L'ideale eroico del rinascimento e le sue premesse umanistiche* (Naples: Edizioni Scientifiche Italiane, 1961). Useful articles appear in *Renaissance Studies* and in *Bibliothèque d'humanisme et de renaissance*.

RENAN, JOSEPH ERNEST (1823–1892)

Joseph Ernest Renan, the French critic and historian, was born in Tréguier, Brittany. He studied for the priesthood at seminaries in Paris but left the seminary of Saint-Sulpice in 1845 to devote himself to secular teaching and writing. He contributed to the *Revue des deux mondes* from 1851 and the *Journal des débats* from 1853. He received a *docteur ès lettres* in 1852, was elected a member of the Académie des Inscriptions in 1856, and was elected to the Académie Française in 1878. He was appointed professor of Hebrew at the Collège de France in 1862, but the course was then immediately suspended until 1870. In 1884 he became administrator of the Collège de France.

Renan's abandonment of his priestly calling was largely determined by the doubts engendered by his philological study of the Bible. After leaving the seminary, he was strongly influenced by Marcelin Berthelot, the chemist, with whom he maintained a lifelong friendship. Another major influence was German idealism, particularly that of G. W. F. Hegel.

In one sense Renan's life's work can be seen as an attempt to expand the horizons of scientific rationalism by incorporating into it what was valid in idealist philosophy—principally the theme of development, particularly the theme of spontaneous evolution of the human mind. It was the historical aspect and the historical emphasis of Hegel's thought that appealed to Renan, for the cast of his own mind was fundamentally historical, not philosophical. Philosophy for him is not a discipline in its own right, and it is history, not philosophy, that should dominate science; "History is the necessary form of the science of the future." It is evident that Renan used the word *science* in the original sense of "knowledge"; "science" is not to be equated with the natural sciences. On the other hand, his philological and historical method is rationalistic and critical. He was interested, above all, in the evolution of languages and religions as manifestations of the development of the human mind, which is in turn the key to the universe. These manifestations and the universe itself, however, are concrete realities to be discovered through observation, experiment, criticism, and disciplined imagination. They are susceptible to this approach because they are the products of the interplay of natural causes according to constant laws. Renan denied in principle that there is any mystery in the world; what seemed mysterious would yield before the advancing frontiers of knowledge. This is the case in the human no less than in the natural

sciences. Renan, in contact with working scientists, rejected the simplistic notions of natural science characteristic of the positivism of Auguste Comte. He maintained that progress in the natural as well as in the human sciences depends on human judgments of the balance of probabilities on the evidence. He further maintained that all reality is in some degree historical, that the natural sciences (paleontology, for example) reveal the remote parts of history, and that the human and natural sciences can and must therefore be of mutual help.

Just as he banished all traditional metaphysics from philosophy, Renan rejected any supernatural content in religion. The true religion of humankind, in the sense of “a belief accompanied by enthusiasm which crowns conviction with devotion and faith with sacrifice,” is that of science (that is, knowledge). Renan’s argument runs as follows: The universe is characterized by change according to “laws of progress” under which the human mind becomes increasingly conscious of itself and the ideal is increasingly manifested amid the real: “The goal of the world is the development of mind.” At the end of the process God, in the sense not of a creative providence but of an immanent ideal, will be realized. Since this ideal consists in the complete development of consciousness and in the attainment by that consciousness of the full measure of beauty and morality of which it is capable, science must be the great task of humankind. This task must be approached in the spirit neither of mere curiosity nor of mere utilitarianism but in the true religious spirit, seeking revelation of the divine.

The above sketch of Renan’s thought is based mainly on his youthful work, *L’avenir de la science*, written in 1848 but first published in 1890. In his later philosophical writing he modified, but did not abandon, the fundamental position adopted there. Political and social events in France, in particular, damped his optimism and strengthened his skeptical and ironical streak. He began to have doubts about the “religion of science” to which he had turned when he abandoned Roman Catholicism. He became less sure that men had the capacity to attain adequate knowledge, and some of his own writing became tentative, cast at times in the form of dialogue. In his professional historical work, however, which always remained his chief concern, he stood fast by his views on the development of rationality out of instinct and on the progressive realization of God on Earth. Even in the new preface that he added to *L’avenir de la science* on its publication late in his life, Renan declared that his religion was still “the progress of reason, that is to say, of science.” He had been too sanguine, too anthropocentric, and not

entirely emancipated from Catholicism; the growth of knowledge had not, in fact, clarified human destiny. He confessed that he did not see how humankind could maintain its ideals if deprived of its illusions, but he retained his faith in knowledge as the supreme pursuit.

RENOUVIER, CHARLES BERNARD (1815–1903)

The French critical philosopher Charles Bernard Renouvier was born in Montpellier and was educated at the École Polytechnique, where he specialized in mathematics and natural science. At the school he came under the influence of the work of Antoine Cournot and of Auguste Comte, who at that time was an instructor (*répétiteur*) in higher mathematics there. In 1848 Renouvier published in Paris his *Manuel républicain de l’homme et du citoyen*, a volume addressed to schoolteachers, which urged the

preaching of socialism. But his political views were frustrated by the coup d'état of Louis Napoleon, and he retired from active participation in politics to write philosophy. Renouvier never held an academic position but worked as a private individual, producing one of the longest series of philosophical works in French history. In 1867 he began the publication, with his friend and collaborator François Pillon, of *L'année philosophique*, a monthly that propagated Renouvier's philosophical doctrines. These doctrines were chiefly expounded in a series of books, constantly revised by Renouvier, the *Essais de critique générale*, the final edition of which appeared in 1897. He continued writing up to the time of his death, his last work being *Le personalisme* (1903). Though his pluralism and his personalism anticipated some philosophical doctrines of the early twentieth century, his main influence was upon his French contemporaries.

NEOCRITISM

Renouvier's general position is called neocriticism, because it took the method of Immanuel Kant's critical philosophy as its starting point. But though Renouvier started with Kant's method, he did not accept Kant's conclusions but used them rather as a basis from which to launch a set of ideas often critical of Kant.

Renouvier laid down as an integral part of his philosophy what he called the "law of numbers," according to which every cardinal number is an ultimate individual, finite and irreducible. Mathematics is the paradigm of thinking, and the law of contradiction is more clearly manifested in mathematical operations than anywhere else. But the term *mathematics*, as Renouvier used it, was restricted to arithmetic, and he derived the nature of numbers exclusively from the cardinal numbers. This led him to deny the existence of any infinite, for he maintained—unable to anticipate the work of Georg Cantor—that an infinite number was a contradiction in terms. Renouvier extended his criticism of the notion of infinity beyond numbers to deny the infinity of space and time as well.

Renouvier recognized that knowledge is relative to its premises and to the person who laid down the premises; nevertheless he could not accept the relativity of logical processes. There is a distinction involved here between logic and the psychology of thought. Just as each number is a distinct and separate entity, so is each human being. And just as the characteristics of each number—duality, triplicity, and so on—can never be reduced to, or "reconciled" with, the characteristics of any other number, so each human being is not exactly like any other and can-

not be merged into a general group-consciousness or absorbed into an absolute mind. Knowledge is always the property of individual knowers, and the distinction between knowledge and belief disappears. What an individual knows is what seems reasonable to him, and his contribution to knowledge can never be subtracted. The subtraction can be made verbally, to be sure, but to do so is to alter the character of cognition, which is essentially judgment.

PHENOMENA

Renouvier also differed from Kant in his doctrine of phenomena. Phenomena are not the appearances of anything other than themselves. They are neither illusions nor purely subjective beings. They are *sui generis*, being whatever we perceive or whatever we make judgments about. He granted that the name is unfortunate except insofar as it indicates appearances. Because there are no things-in-themselves, Renouvier criticized Kant's antinomies, which hold good only if there are noumena. His attack on the first antinomy, for example, was based on its use of the concept of infinity. Since infinity is an inherently inconsistent idea, Renouvier asserted that the world must have had a beginning in time and that space is limited. The domination of the number concept as a conceptual model appears here in full force. For Renouvier, the numbers begin with one, since zero and negative numbers are not really numbers, and spaces are the spaces of individual discrete beings, there being no such entity as number-in-itself or space-in-itself.

There exists within the number series the category of relation. For the numbers are ordered, and order is a kind of relation. All other categories are, for Renouvier, forms of relation, but of relation as discovered within the framework of an individual's consciousness. There turn out to be nine categories—relation, number, position, succession, quality, becoming (*devenir*), causality, purposiveness, and personality. Each has its thesis, antithesis, and synthesis; and all are rooted in the phenomenal world as judged by us. It is uncertain whether Renouvier attempted to derive his categories in the manner of Maine de Biran from personality—our acting as a cause, our seeking ends, our sensory discriminations (which might produce the separateness of quantity and quality), spatial positions, moments in time, and the intervals between them—or whether his assertion that personality is one of the categories is derived from his premise of the law of numbers. In any event, just as each number has its own distinctive quality, its own position in the numeral order, and its many relations to other numbers, determined not

only by its own character but also by that of the other numbers, so the human being has his own personality and displays the other categories not only as a distinct entity but also as a perceptive consciousness.

The parallelism between the ways in which a man judges, perceives, and knows and the ways in which he as a person differs from other beings pervades Renouvier's writings. Thus, because one acts to achieve one's purposes, it follows that both causality and purposiveness exist within the human being and must likewise be combined in the phenomenal world. A cause determines the path of an event, but the direction of that event is determined by that which participates in it.

Since no two events are exactly alike, the deterministic factor in nature is mitigated by chance. Renouvier probably got this argument from Cournot, who also insisted upon the probabilistic element in nature. To frame a law or a generalized description depends upon our ability to discover absolutely homogeneous phenomena or groups of phenomena. If this is impossible, then generalizations are at most only probable. But at the same time, each individual phenomenon contributes something to the events of which it is a part, and that contribution in the very nature of things cannot be predicted.

INDETERMINISM

The problem of causation arises with regard to human beings in the form of the antithesis between free will and determinism. Since every act of consciousness is a relation between a perceiving subject and that which is perceptible, then as soon as a conscious act is formulated and made clear to the perceiving mind, it will be organized in terms of the categories. But there is a choice among the various categories to be applied, for we are not forced either to quantify or qualify, to count or to locate, to assign a date or to recognize a cause. The categories limit the possibilities of judgment but have no inherent order of predominance. In other words, Renouvier held that when we see a phenomenon, for example, a tree, we are not forced first to judge it as green, then as distant, old, fan-shaped, simple, or what you will. The order of judgment is determined by us, and we are free, within the range of possible categories, to judge it as we will. The selection of a category or group of categories depends on our free choice in accordance with our interests at the moment of judging.

Freedom cannot be proved, nor can determinism. Both are assumptions utilized in view of their consequences. These consequences may be purely intellectual or may be moral or practical. But freedom itself rests

upon the inherent individuality of the human will, an individuality which cannot be completely absorbed into any larger class of beings. Insofar as any being is unique, to that extent it is undetermined or self-determined. And insofar as it is identical with other beings, to that extent the homogeneity of its class accounts for the regularity of its behavior. In short, individuality and freedom are synonymous terms, and Renouvier even called freedom the principle of individuation. The consequence is that just as the personal equation enters into all judgments, so the only certainty we have is the certainty of our judgments. Renouvier put it as follows:

Certitude is not and cannot be absolute. It is a condition and act of man—not an act and a condition in which he grasps immediately that which could not be immediate, i.e., facts and laws external and superior to present experience, but rather one in which he posits his awareness as it exists and as he maintains it. Strictly speaking, there is no certitude; there are only men who are certain. (*Traité de psychologie rationnelle*, Paris, 1912, Vol. I, p. 366)

But indeterminism is not limited to human judgments. It extends also to history. For since history is in part made up of human behavior, human decisions must be included in its scope, and there is no way of eliminating them. One can, of course, describe the environment of human life, its stability, and its mutability; but if it remains stable, that is because human beings have not changed it, and if it changes, that is due to human acts as much as to natural disasters. People modify their living conditions, not as a group acting as one person, but as a collection of individuals. Their reasons for doing so may vary, as is inevitable, and of course they are not able to modify their conditions completely. But Renouvier emphasized the importance of human decisions for the way in which individuals will live, since the ability of human beings to make choices makes it impossible to lay down either a law of universal progress toward the good or one of constant degeneration. Hence Renouvier rejected historical laws, such as those of Comte and G. W. F. Hegel, though he was attracted to meliorism.

ETHICS

If there is no historical law dooming humankind to move in any predetermined direction and if history only records actual change, the question arises of the relation of history to ethics. People make moral judgments and act so as to achieve what they believe to be right. Morals, then, are not the result of history, though what happens

in history reflects our moral judgments. Morals are rather the source of historical changes, and if we are to appraise historical events, we shall have to do so in moral terms. This clearly requires a definition of good and evil, and in view of the radical individualism of Renouvier this might seem an insurmountable task. But he identified evil with conflict, conflict both between persons and between groups of persons. For warfare is in essence the prevention by one or more persons of the fulfillment of the volitions of others. Hence tyranny, slavery, and conquest are to be condemned. This assumes that it is possible for a group of enlightened people to respect the individuality of their fellows and for all to live in peace.

In his fictional account of what history might have been, *Uchronie* (1876), Renouvier claimed that the secret of human happiness lies in our recognition of the individual's freedom. If at any epoch people had accepted individual freedom wholeheartedly, he argued, universal peace and harmony would have prevailed. Religious, economic, and national wars would have ended at once; for everyone would have taken it for granted that each person has a right to his own religious views, to the satisfaction of his own economic interests, and to his own national loyalties. Renouvier held that education alone could bring this about, though he had no illusions that proper education was ever likely to be instituted. The dogma of historical determinism has had too firm a hold on human will power and has brought about acquiescence, sloth, injustice, and ignorance.

The basic premises of Renouvier's *Science de la morale* (1869) are that human nature is rational and that people believe themselves to be free. Their belief in freedom leads individuals to act for what they judge to be better, and their rationality guides them in their choice of ends. To act morally is to act rationally. By doing so we rise above the beasts; we recognize the humanity in our fellows and respect it. For this reason Renouvier became a bitter opponent of the Catholic Church and of monarchy and urged his readers to turn to Protestantism as the religion of individual conscience. To him Protestantism was the religion of a personal God—not an absolute and unchanging Being, omniscient and omnipotent, but finite, limited, free, and the guarantor of our freedom. God's existence is not proved, but it is a reasonable hypothesis drawn from the existence of our moral objectives. Running through Renouvier's many works are the premises that the plurality of existing things is irreducible; that chance is real and is reproduced in individual freedom of choice; that time and novelty really exist; and that no absolutes or infinities exist.

RENSI, GIUSEPPE (1870–1941)

Giuseppe Rensi was an Italian skeptical philosopher and professor of philosophy at the universities of Messina and

Genoa. Rensi first upheld a religiously or theistically oriented idealistic philosophy, defending it in a number of essays and fostering it through his translations of the works of Josiah Royce. He contrasted his theistic “constructive idealism” with the “immanentistic idealism” of Benedetto Croce and Giovanni Gentile; he regarded the latter as a temporary position that, if developed coherently, would have led to constructive idealism. According to Rensi, an idealism that does not arrive at God subtracts reality both from the external world, which then becomes a set of ideas, and from the human spirit, which is then resolved into a set of ideas without a subject.

After World War I, regarded by Rensi as proof of the fundamental irrationality of the world, he began to defend a radical skepticism based on the multiplicity, irreducibility, and irreconcilability of opinions, the reasons used to justify them, and some aesthetic tastes and moral ideas. Rensi held that the traditional objection to skepticism—that it contradicts itself by asserting that there is no truth while dogmatically asserting its own truth—was a purely verbal objection, because the skeptic holds his position against any doctrine taken in itself by showing the contradictions and shortcomings of that doctrine. Therefore the skeptic does not assert that there is no truth but instead that a particular doctrine that claims to possess truth does not and cannot possess truth. Skepticism, in other words, shows the disagreement of reason with itself both within the views of one man and between the views of different individuals. War, the conflict of rights and of political powers, and the contradictory character of philosophies are, according to Rensi, proofs of the intrinsic contradiction in reason. Skepticism does not exclude faith but stems from the preservation of faith. The skeptic is skeptical not because he does not believe but because others believe differently than he; that is, they believe that which he considers absurd.

Rensi had been a socialist in his youth but later came to defend authority. He wished to give to power (and even violence) the function of helping man escape from the chaos of opinions and contrasting interests and of forming a people into an economic, political, and spiritual unity. Authority need not base itself on reason, because it creates for itself the reason of all that it wishes. Although these ideas seem close to those of fascism, Rensi quickly declared himself opposed to fascism and remained so until his death.

According to Rensi, skepticism implies atheism in the field of religion. The refinement of religion that leads to regarding God as inaccessible to the senses and to human powers makes God a nonbeing, the pure and sim-

ple negation of every reality accessible to man. From this point of view, both negative theology and mysticism demonstrate atheism. Atheism is still a religion because it is an answer—even if a negative one—to the problem of supreme reality. Unlike other religions, atheism is absolutely disinterested because it contains no egoistic motive and because it places man before the mystery of the All without his being able to expect from the All any help for his own needs.

After 1922, when the absolute idealism of Croce and Gentile assumed the status of an official or semiofficial philosophy in Italy, Rensi accentuated his polemic against it and affirmed the theses most opposed to those of idealism: materialism and pessimism. The Kantian system, considered to be idealistic by the idealists, seemed to Rensi to justify materialism because the Kantian forms of intuition and of thought that condition phenomena, and therefore the totality of nature, are not created by the self but constitute “consciousness in general,” which is the intelligibility of the things themselves. According to Rensi, the Kantian doctrine is, therefore, that nature gives reality and knowability to natural things, that things generate of themselves, and of themselves are spatial, temporal, perceptible, and representable; in one word, they are material.

Rensi held that materialism implies pessimism because a material nature deprived of any finality offers man no guarantee and necessarily includes evil, error, and conflicts. For a man who lives in such a nature, morality, when not based on an egoistic calculus or subjected to an imposed code, is a disinterested recognition of evil and a protest against it. It is therefore pure folly. Nevertheless, all of Rensi’s works contain a mystical and religious strain, a sense of mystery and of a force that, the triumph of evil in nature and in history notwithstanding, reveals itself in the interiority of man. Rensi condensed this feeling into the phrase “Atoms and the void—and the divine in me.”

REPUBLICANISM

Republicanism is one of the great traditions of Western political thought. To say that republicanism is a “tradition” of political thought is to say that distinctively republican ideas about politics have been championed by a number of authors in the history of political theorizing, and that many of the later authors who championed those ideas consciously drew on and developed the work of earlier ones. This continuity of reference and influence makes it possible to trace a republican strand in Western political writing. But what ideas about politics are distinctively republican? What ideas define the republican tradition?

The republican tradition is often associated with the claims that citizens can only be free in a free society, that the opposite of freedom is a state of dependence akin to slavery, that societies are most likely to enjoy freedom and to realize their common good when they are governed by politically engaged citizens who act from the civic virtues, and that the pursuit of the common good is undermined when citizens’ virtues are corrupted by selfishness, luxury, and ambition. These claims turn up consistently in the writings which make up the republican tradition from Rome at least through the eighteenth century.

The classic texts of the republican tradition were produced in political circumstances very different than those of the early twenty-first century. These texts commend ways of life, such as a life of politically active citizenship, that are open to relatively few citizens of large, modern societies such as England and the United States. The political threats in the face of which these texts were

produced were quite different than the threats to liberty and equality posed by the modern states of late capitalism. Republicans’ emphasis on civic virtues raises the possibility that republican politics would be difficult to sustain under conditions of moral pluralism. It is therefore not immediately clear that republicanism can provide guidance to modern politics. Even if republican ideas can provide some guidance, it is far from clear that republicanism alone can provide sufficient guidance. Perhaps republican ideas about politics are most useful as supplements to political theories that belong to other traditions of political thought and that are explicitly framed for current conditions.

Republicanism has enjoyed a revival in legal and political philosophy since the 1980s. Those who have revived republicanism in these disciplines have tried to apply the insights and arguments of the tradition to contemporary politics. But some participants in the revival themselves seem to raise questions about the sufficiency and distinctiveness of republicanism. They move easily between republicanism and democratic liberalism and seem content to describe themselves as both republicans and liberals. The fact that they do so raises questions about whether any version of republicanism that is of more than historical interest is faithful to ideas that have distinguished the republican tradition. It also raises questions about whether versions of republicanism that bear on contemporary politics are part of a strand that ought to remain distinct from other movements of political thought. Perhaps the insights of republicanism are best absorbed into liberalism, a tradition which has its origins in the early modern period.

Late twentieth-century work on republican views of liberty has, however, changed the way historians and political theorists think about republicanism. It has already shed new light on some of the classic texts in the republican tradition. It promises to show how some of the claims characteristic of republican writing can be systematically united and given a theoretical basis. And it promises to illuminate deep and interesting differences between republicanism and liberalism. If these promises can be made good, then republicanism’s claim to be a distinctive family of political thought—and one of continuing relevance—can be vindicated.

ROMAN REPUBLICANISM

The origins of the republican tradition lie in the writings of Roman political thinkers, such as Cicero and Sallust, who lamented and analyzed Rome’s transformation into an empire just before the beginning of the common era.

They came to be called “republicans” in part because the form of government they favored was that of pre-imperial Rome—a regime for which Cicero popularized the name “the republic.” They are also called “republicans” because of the features of that government that they seized upon when arguing that rule by the republic’s government was superior to imperial rule. The words “republic” and “republicanism” derive from the Latin phrase *res publica*, which means “public matter.”

According to these thinkers, the republic was better suited to advance the common good of the Roman people than the empire was because, unlike the empire, its government was participatory. It was governed by public-spirited citizens—in particular, public-spirited citizens serving in the Roman senate—who devoted themselves to the pursuit of public matters rather than to the pursuit of their own wealth and ambition. In the “Dream of Scipio,” Cicero famously claimed that those who dedicate themselves to the preservation of the republic would enjoy an eternal reward. Such devotion to the republic, he thought, required civic virtue. Republican writers claimed that the Roman republic was subverted by corruption. It was subverted, they said, by those who sought and used political power to further their own ends rather than the common good of the Roman people.

RENAISSANCE AND EARLY MODERN REPUBLICANISM

Republicanism had little impact on the political thought of the Middle Ages, though some of the writings of Cicero were certainly known to such great medieval philosophers as Augustine and Thomas Aquinas. But the writings of the Roman republicans were important sources for political thinkers in Renaissance Italy who wanted to maintain the freedom of city-states against internal and external threats. They were also important sources for thinkers in seventeenth-century England who opposed the absolutist tendencies of the Crown. These writers located themselves in the tradition of Roman republicanism. They drew on republican claims about the importance of political participation, the need for a virtuous citizenry and the threats posed by corruption and self-interest, even as they adapted those claims to their own situations.

Among Italian thinkers, the greatest was undoubtedly Machiavelli, especially the Machiavelli who wrote *The Discourses*. Machiavelli believed that the citizens could only enjoy freedom if their city was free. One of the most significant threats to a city’s freedom, he argued, was an internal threat: the threat posed to a city’s good

government by factions that would pursue their own interests once in power. Inspired by the political ideas of the humanist tradition and the writings of Roman republicans, Machiavelli argued that the dangers of factionalism could best be averted by a government of citizens committed to the common goods of civic wealth, glory, and independence.

English republicans such as John Milton and James Harrington were less concerned with the threat of faction than they were with what they regarded as the absolutist tendencies of the monarchy. They maintained that absolute power corrupted, but it did not corrupt only the monarch. A powerful court, they thought, was one that corrupted courtiers and politicians by encouraging their dependence upon royal favor. English republicans stressed the importance of the civic virtues, among which they numbered independence and frugality. They held up as models of good government the republics of Renaissance Italy, and the Roman republic. Historians sometimes call them “commonwealth men” because of their support for the Puritan commonwealth.

THE REPUBLICAN REVIVAL

The last third of the twentieth century saw a resurgence of scholarly interest in republicanism, primarily but not exclusively in the English-speaking world. The resurgence of interest among American Constitutional lawyers in the 1980s and 1990s came to be known as the “republican revival.” That term can be stretched to encompass the contemporaneous revival of interest in republicanism among political philosophers. The republican revival among lawyers and philosophers was preceded by and drew upon work by historians of Renaissance political thought and by historians of the American founding. Indeed it was because of the resurgence of interest among historians that so much has been learned about early modern republicanism. It is useful to begin a survey of the republican revival with a look at some of the historical work that preceded and influenced legal philosophers responsible for the revival.

In the 1950s Louis Hartz articulated what was for a time the received orthodoxy about the intellectual foundations of the American Revolution and founding. According to Hartz, the revolutionaries and founders owed their greatest intellectual debts to the classical liberalism Hartz ascribed to John Locke. In the 1960s historians of the American founding and its intellectual antecedents, notably Bernard Bailyn and Gordon Wood, raised serious challenges to this orthodoxy. Bailyn and Wood argued powerfully that the intellectual underpin-

nings of the revolution and the founding period were in large part republican, drawn from the English commonwealth tradition of the previous century. John Pocock, who traced the origins of the commonwealth thought to Renaissance Italy, provided an even longer genealogy for American republicanism.

Bailyn and Wood mined the pamphlets and popular literature of early America for evidence of republican political thinking. The expressions of republicanism they found there included pervasive emphasis on the need for citizens to dedicate themselves to the common good and on the deleterious effect of faction and the elevation of private over public interest, concern with the corrupting effects of various forms of dependence upon Britain (including dependence on its monied and manufacturing interests), and the description of American dependence as a condition of slavery. Pocock, Bailyn, and Wood all maintained that the republicanism of the American founding was only gradually eclipsed by other forms of political thought in the years or decades that followed.

The question of whether and to what extent the American founders were republicans is a question of some importance for legal philosophy. The founding period of the United States was the period in which the body of the American Constitution and the Bill of Rights were written. The conclusion that the founders owed deep intellectual debts to republicanism arguably has profound implications for how the Constitution and the Bill of Rights should be read and applied. The argument that it has such implications seemed especially pressing to legal scholars at a time when some were defending originalist canons of Constitutional interpretation. In the 1980s Constitutional scholars began to draw on the historical work of Pocock, Bailyn, Wood, and others, and initiated the republican revival in legal scholarship.

The leading figures of this revival, such as Cass Sunstein and Frank Michelman, emphasized the participatory strain of republicanism. Republican government, according to these thinkers, is government by citizens who participate in politics. The politics in which they are to participate is to be deliberative: citizens of a republican regime are to participate in collective deliberations about public matters. Such public deliberation, they argued, promises to combat the factionalism and self-interest that republicans had traditionally seen as undermining good government. It does so because the process of deliberating with others is not one of bargaining in which parties try to satisfy the preferences they have formed before public deliberation begins. Rather, it is to be a process of reasoning with others about how to advance the common

good. When citizens reason together about the common good, they are forced to rethink whatever self- and group-interested preferences they may bring into public deliberation.

Republican accounts of politics had previously been addressed to societies much smaller than the democracies of the late twentieth century. Framing a version of republicanism adequate for such large societies required imagining institutional forms through which republican government could be exercised within them. The leaders of the republican revival in the law offered republican readings of the American constitution and drew out the implications of those readings for a host of questions in public law, from environmental law to campaign finance reform.

The republicanism offered by republican revivalists in the legal academy—like the republicanism uncovered by historians of the American founding—emphasized the value of political participation, the importance of their commitment to the common good and the threat posed by citizens' unregulated pursuit of self- and group-interested preferences. Because of these emphases, republicanism seemed to offer a healthy corrective to the individualism, self-interest, acquisitiveness, and withdrawal from public life that some thinkers, such as Michael Sandel, have alleged that liberalism encourages. Yet the republicans in the legal academy saw significant continuities between their own views and some forms of liberalism, particularly between their own views and the version of liberalism developed and refined by John Rawls from the 1960s until his death in 2003. By a decade after the republican revival began in American law schools, some of its leading figures had ceased to insist that there was anything distinctively republican about their views. Even some who continued to describe themselves as republicans, such as Sunstein, also described themselves as liberals and “deliberative democrats” as well. The development of a republicanism that was explicitly contrasted with liberalism had to await the republican revival in constructive political philosophy.

According to some leading republican political philosophers, the differences between republicanism and liberalism lie, not in the former's emphasis on political participation and civic virtue or in the latter's emphasis on individual rights, but in the very different conceptions of political freedom associated with each. Liberalism, as its name suggests, is a political philosophy that values liberty. The liberty that liberals are sometimes said to value is what has come to be called “negative liberty.” Someone enjoys negative liberty to the extent that she can act as she

likes, without external impediments. Political liberty is the freedom citizens enjoy in political society. Those who identify political liberty with negative liberty must think that even the best law is an external impediment to action, and so interferes with citizens' political liberty. If they also think, as liberals do, that it is the job of government to promote and secure political liberty, then they must also think government should rely as little on these impediments as possible. It should secure as much negative liberty for citizens as is compatible with the enforcement of laws needed to maintain public order.

Some of the most prominent republicans who have contrasted their views with liberalism have contrasted them with versions of liberalism which equate political liberty with negative liberty. They have introduced another kind of freedom, which they call "freedom as nondomination." They have argued either that political liberty includes both negative liberty and liberty as nondomination, or that it consists in liberty as nondomination alone. To appreciate the differences these republicans see between liberalism and their own views, it is necessary to see what it is for one agent to dominate another.

One agent dominates another just in case the former is in a position to interfere arbitrarily with the choices of the latter. An agent is in a position to interfere arbitrarily with another's choices just in case that agent is able to interfere with the other's choices without having to take the latter's interests into account. This way of characterizing domination implies that there are two important differences between liberal views which identify political liberty with negative liberty and republican views which either equate political liberty with liberty as nondomination, or which claim that political liberty includes liberty as nondomination.

One difference is that, according to the latter, not all laws restrict citizens' freedom. When political authorities take account of the interests of citizens in the enactment and enforcement of law, they do not dominate citizens. They do not dominate them because, though the laws may interfere with citizens' freedom of action, they do not do so arbitrarily. Therefore, though these authorities compromise citizens' freedom on liberal accounts which equate liberty with negative liberty, they do not do so on republican accounts.

The other difference is that republicans think one person can restrict another's liberty just by being in a position to interfere with him arbitrarily, even if she never actually interferes with him at all. Thus a political authority who can exercise power without accountability, but who chooses to enact laws which further the common

good, still dominates citizens. These citizens therefore lack political freedom on republican accounts but not on liberal ones.

The account of liberty as nondomination has been stated and defended most notably by Philip Pettit, beginning in the mid-1990s. Pettit labels that account of freedom a "republican" account because he claims that it is found in the seminal texts of the republican tradition. He argues quite convincingly that, by taking freedom understood as nondomination as the supreme political value, he can account for why republicans have valued political participation and why they have maintained that citizens are free only in free societies. Quentin Skinner, the historian of Renaissance republicanism, also has claimed to have found a distinctive conception of liberty in the republican tradition. In response to Pettit's work, Skinner has argued that republican political liberty includes both negative liberty and liberty as nondomination. Whether Pettit's or Skinner's view of political liberty is more faithful to the texts remains a matter of scholarly debate. What is beyond debate is that Pettit's conceptual work on republican liberty has greatly influenced historical work on republicanism, and that Pettit and Skinner have taken the republican revival to a new level of philosophical sophistication. Questions remain, however, about exactly where their versions of republicanism differ from prominent forms of liberalism which do not equate political liberty with negative liberty.

The liberalism developed by Rawls in the last third of the twentieth century has been enormously influential. Rawls argued for principles of justice which, he maintained, would be agreed to in what he called "the original position." The original position is, like the state of nature in Locke's work, a condition appropriate for writing a social contract. Thus the principles of justice Rawls defends are principles citizens would choose for themselves under the conditions appropriate for such a choice. Rawls calls a society which is regulated by those principles a "well-ordered society." When citizens live in a well-ordered society and when their own plans are in accord with the principles of justice, they live under and act from principles they would give to themselves. To be autonomous is, literally, to give oneself a law. Citizens who live in a well-ordered society and act from principles they would give themselves therefore enjoy an important form of autonomy, which Rawls calls "political autonomy."

One question republicans need to answer is how their view of political liberty differs from a view of political liberty like Rawls's, according to which political lib-

erty includes political autonomy as an important ingredient. Another is whether they think Rawls's well-ordered society would include injustices or obstacles to freedom—for example, instances of domination—that a republican regime would not. This question will require a complicated answer because, while Rawls thinks that political freedom includes political autonomy, he does not equate the two. He insists that, in a well-ordered society, the liberties exercised in political participation will have what he calls “fair value.” Citizens' possession of political liberties which have fair value may be required by their political autonomy, but it seems to be distinct form of political freedom. Moreover, it is at least arguable that when citizens enjoy this form of political freedom—when these liberties have fair value—much of the political domination that concerns republicans will be eliminated. Finally, republicans need to ask whether a republican society would allow injustices that a well-ordered society would eliminate.

Republicanism has undoubtedly been a philosophically interesting tradition of thought which exercised great influence at important points in Western political history. Since the late twentieth century it has been revived with brilliance and ingenuity. But until contemporary republicans answer these questions, it will be difficult for them to maintain that republicanism is superior to all forms of liberalism. Until they answer them, it will also be unclear whether republicanism can stand on its own as a theory of contemporary interest, or whether the insights that have been systematized by its most sophisticated exponents are better incorporated into some version of liberal theory.

Paul Weithman (2005)

RESCHER, NICHOLAS

(1928–)

Born in Hagen, Germany, where his father had established a law practice after serving as a German army officer in the First World War (1939–1945), Rescher's family emigrated to the United States in 1938, and he was educated there, receiving his PhD from Princeton University in 1951 at the age of 22. Since 1961 he has taught at the University of Pittsburgh, where he serves as University Professor of Philosophy and also as vice chairman of the Center for the Philosophy of Science. He has published more than 300 articles in scholarly journals, has contributed to many encyclopedias and reference works, and has written more than 100 books in various areas of philosophy, including epistemology, metaphysics, value theory and social philosophy, logic, the philosophy of science, and the history of logic.

In various publications Rescher has developed a detailed and systematic theory on the nature and limits of human knowledge along with its central implications for metaphysics and for the theory of values and ethics broadly conceived. Best viewed as an analytic pragmatist, Rescher has sought primarily in many books and essays to revive and refurbish the idealistic tradition in epistemology and metaphysics. Although he has written extensively on metaethics and issues of value and justice, his primary

efforts in epistemology and metaphysics constitute the central focus, and his approach to philosophy is comprehensively expressed in a trilogy titled *A System of Pragmatic Idealism*.

Generally, Rescher affirms the centrality of the natural sciences as the privileged source of understanding the nature of the empirical world and as directing our actions within it. He emphasizes, however, that the presuppositions of the natural sciences cannot be directly defended in natural science without circularity; such presuppositions, therefore, fall into the realm of metaphysics and are to be defended philosophically, philosophy being distinct from, but inextricably dependent on the deliverances of, natural science.

Rescher also sees the scientific method(s) as the product of an evolutionary process of rational selection, which leaves us with only those methods that have been proven to work by way of providing reasonably precise predictions of our sensory experience. In short, the methods of natural science, as well as their presuppositions, find their justification ultimately in the fact that we have a deep need for the products of natural science and epistemology, thereby underscoring the deeply practical or pragmatic nature of the whole of the cognitive enterprise, and whatever theoretical conclusions we reach therein (Rescher 1992–1994, 2001).

Regarding foundational beliefs or basic knowledge, Rescher affirms that basic beliefs, like all factual beliefs, are fallible and hence subject to revision in the light of ongoing evidence. Such beliefs begin as working presumptions about how things generally are, and are accepted as true until experience requires their rejection, but until experience forces such rejection they qualify for acceptance as items of human knowledge and serve as evidence for other beliefs, nonbasic beliefs. On the question of nonbasic knowledge, or scientific knowledge, he has consistently argued in *Methodological Pragmatism* and elsewhere that while particular scientific theses established by the inductive methods of science may be false (although we must presume them to be true when strongly confirmed), rationality requires us to use such a method because they generally tend to produce more effectively supplementable beliefs about the physical world than any other methods available.

Rescher construes truth in terms of any classical formulation of the correspondence theory of truth satisfying Alfred Tarski (1902–1983) biconditionals, and he argues that the criterion for it is fully warranted, assertible belief. The satisfaction of this criterion in any given case, however, does not entail logically that the proposition is true

rather than our best estimate of, or approximation to, truth; and it would be irrational to ask (as skeptics do) for anything more in the pursuit of truth, for nothing more can be had (Rescher 2003).

At no time, then, can we be sure of having the truth, rather than a reliable, but fallible, estimate of how things are, and it is this essentially fallibilistic conclusion that leads to Rescher's antirealistic view that we cannot be sure at any given time whether science actually succeeds in correctly describing an external world, although indeed we have good reason in this fallibilism to suppose that there is an external world. And this same fallibilism leads, with the support of various arguments, to the essential incompleteness of our knowledge of the world (Rescher 1978, 1999, 2000a, 2001, 2003). His idealism is consciously not an idealism affirming that all properties are linguistic in nature, but it does emphasize the fact that all systems of knowledge are the products of pervasive and profound human cognitive construction (Rescher 2001).

By way of philosophical methodology Rescher adopts a view he calls philosophical standardism. He thinks, for example, that human knowledge is fundamentally and standardly a matter of justified true belief. Prevalent counterexamples to the classical definition of knowledge as justified true belief are maximally distortive of the fact that philosophical explanations are based on limited generalizations that are subject to revision and we seek what is normally and typically the case rather than what is unexceptionally and necessarily the case (Rescher 1994, 2003). For Rescher, then, traditional philosophy is too much given over to abstract necessities of general principle that do not capture our understanding of the world as it is actually experienced, and the price we pay for his more modest construal of philosophical generalizations is to acknowledge the essential open-endedness of our philosophically relevant concepts.

By way of compensation for this less demanding view of philosophical methodology, Rescher urges that we can resolve a host of philosophical problems, such as the Gettier problem that have lingered too long because of the mistaken and pervasive belief that philosophical generalizations will be adequate only if they do not admit of exception in any context (Rescher 1994, 2003). Rescher argues, then, for a different view of conceptual analysis, a view allowing us to resolve the Gettier problem as well as the problem about the concept of meaningfulness in empiricism. For example, he argues that the classical definition of knowledge in terms of justified true belief has led to a hopeless set of counterexamples and counter-definitions simply because people think mistakenly that

counterexamples refute a concept defined, and this mistaken belief roots in a faulty concept of analysis that is traditional and aprioristic.

Rescher's proposal is that we construe the relationship between knowledge and justified true belief not as a definition, but as a merely standardistic or generalized linkage under which "Standardly, knowledge is justified true belief" is a perfectly acceptable generalization, not only plausible but largely unproblematic. For Rescher, in the context of an epistemological standardism, interpreting such generalizations in a standardistic way does not allow the definition to be annihilated by counterexample. After all, as he says, knowledge is pretty standardly justified true belief. This same approach he applies to the empiricist criterion of meaning.

Although Rescher ascribes a certain primacy to induction and the methods of natural science because they are the products of the evolutionary process, he has not argued that the only legitimately answerable questions are those that admit of answer under the methods of science. He in fact has argued against that view when, among other arguments, he defends metaphysics as that philosophical venture seeking to examine and criticize the presuppositions of natural science, which natural science cannot do without viciously circular reasoning. He also has claimed that such presuppositions find their ultimate justification in the ultimate consequences, formal and material, of accepting them and their capacity to satisfy human needs for practical adaption.

On the question of scientific progress Rescher has aggressively argued in various places that unto eternity science is progressive and revolutionary, meaning thereby that there will never be a time when we would be justified in believing that we had answered all answerable questions about the world. Owing to an inevitable exponential decay in our economic capacity to fund scientific technology, scientific progress will accordingly slow, without stopping, to increasingly infrequent theoretical and factual advances. But it will always be an open-ended and unfinishable affair (Rescher 1978, 2000a, 2000b, 2003).

With regard to scientific realism, Rescher advances a cautious form of scientific instrumentalism without endorsing instrumentalism as a whole on the issue of factual knowledge. For Rescher, commonsense beliefs (those beliefs so obviously true that we cannot even imagine factual conditions under which they would be false) do succeed in standardly describing the physical world because such beliefs are not in any way likely to suffer truth value revision (Rescher 2003). Scientific beliefs, however, have no such property and must, for that reason, be regarded

as instrumentally reliable beliefs that we can plausibly presume true when strongly confirmed.

Otherwise, Rescher's fundamental metaphysical view on the question of reality originates in what he calls his *pragmatic idealism*, which he also sees as an antirealist implication of fallibilism and is an idealism only to the extent that it emphasizes the constructive role of cognitive processes in structuring our beliefs about an external and independent world about which we have knowledge in terms of our capacity to estimate the truth in the light of available evidence and in terms of what we can reasonably ascertain as typically and generally the case. But, it is not an idealism denying the existence of an external world. That such a world exists fundamentally roots in the essentially fallibilistic limitations and incompleteness of our knowledge of the world, as has been demonstrated time and again in the history of science and elsewhere (Rescher 1992–1994, 2000a, 2001, 2003).

In several cases philosophers have associated Rescher's name with a particular concept or principle broadly discussed, most notably in *Rescher's Law of Logarithmic Returns*, *The Rescher Quantifier*, *Rescher's Effective Average Standard* in the theory of distributive justice, *The Dienes-Rescher Inference Engine* in nonstandard logic, and *The Rescher–Manor Mechanism* in non-monotonic reasoning theory.

RESPECT

The ideas that people should be treated with respect and that individuals should respect themselves are important elements of everyday morality and moral philosophy. Some theories treat respect for persons as the basis of morality or the hallmark of a just society, while self-respect is often viewed as a core moral duty or something that social institutions must support. There is disagreement, however, about whether things other than persons, such as animals or the environment, are appropriate objects of respect.

Most generally, respect is acknowledgement of an object as having importance, worth, authority, status, or power. As its Latin root *respicere* (to look back) indicates, to respect something is to pay attention or give consideration to it. As the etymology also suggests, respect is responsive: the object is regarded as due, deserving, or rightly claiming acknowledgement. Respect can be an unmediated emotional response, but it typically involves a conception of certain forms of acknowledgement as appropriate in virtue of some feature of or fact about the object, which is the basis of respect. Respect thus differs from attitudes such as liking, which are based in the agent's interests. Respect also typically involves behaving in ways that show regard for the object or refraining from certain conduct out of respect for it. We can respect rules by obeying them, dangerous things by taking precautions, and authorities by deferring to them; but respect is commonly thought to involve appreciating the value of the object. Valuing respect can be akin to admiration, awe, or honor, but contrasts with valuing modes such as maximizing and using. We can respect things we do not approve of, but regarding something as worthless or irrelevant is incompatible with respecting it.

There are many types of respect. Consider the well-mannered respect children should show parents and teachers, the great respect one might have for accomplished or morally exemplary individuals, the just respect people demand for their rights, the wary respect a prudent hiker has for rugged backcountry, the pro forma respect of standing for the judge entering a courtroom, and the basic respect many believe we owe people simply as people. These can be understood in terms of Stephen Darwall's (1977) now-standard distinction between two

fundamentally different kinds of respect: recognition respect and appraisal respect.

Recognition respect is a disposition to take something appropriately into account in deliberations about action. A diversity of things, including laws, rights, hazards, opinions, social institutions and positions, nature, and people can be objects of different forms of recognition respect. What recognition respect involves in various cases depends on the reasons why objects of that sort should be taken into account. Recognition respect is a moral attitude if the object is regarded from a moral point of view, for example, as having moral worth or as morally constraining actions. By contrast, we have appraisal respect (which some call evaluative respect) only for people, either as persons or in some role or activity, or for their qualities or achievements. Like esteem, it is based on a positive assessment of an individual's merits and admits of degree; but whereas any valued feature can be a basis of esteem, appraisal/evaluative respect concerns the moral quality of an individual's character. In addition, some philosophers regard the feeling of reverential respect as a distinct third kind of respect.

Whereas everyday discourse tends to use "respect" in the evaluative sense, as thinking highly of someone, philosophical attention focuses chiefly on moral recognition respect for persons. Individuals can be owed recognition respect in virtue of their social position (for example, as an elder or judge); such respect involves conforming to conventions for appropriate behavior. However, respect for persons commonly means recognition respect that all persons are morally owed solely because they are persons, regardless of social positions or individual qualities.

The moral philosophy of Immanuel Kant contains the most influential discussions of respect for persons. Kant holds that all and only persons, by virtue of their rational autonomy, are "ends in themselves" and have a special, unconditional worth called "dignity." Respect is the only fitting response to dignity; consequently, we have a fundamental and absolutely binding moral obligation to respect persons as ends in themselves. Moreover, all persons are equal in dignity and moral status with other persons, so each has a right to respect from all as well as a duty to respect themselves. Kant expresses this idea in *Groundwork of the Metaphysics of Morals* (1785) in one version of the categorical imperative, which is the supreme principle of morality: "Act so that you treat humanity, whether in your own person or the person of any other, never simply as a means but always at the same time as an end." In *The Metaphysics of Morals* (1797) Kant

explicates specific ethical duties of respect for others and self-respect.

Kant's account prompts numerous questions. Is rational autonomy indeed what gives persons the unconditional claim to moral recognition respect? Some thinkers argue that this is too thin a view of what matters morally about persons. Are all humans owed respect? What about those who lack rationality, such as profoundly mentally disabled individuals or human fetuses and embryos? Must persons always be respected regardless of moral merit, or can recognition respect be forfeited, for example, by evildoing? Some contend that remorseless evildoers warrant no respect; others hold that while they deserve punishment, they must still be respected as persons. What attitudes and conduct express respect or disrespect for persons? Humiliation, coercion, and enslavement are quintessential forms of disrespect; what positive measures (e.g., helping others pursue their ends, listening to their points of view) does respect require? What does respect imply for issues such as assisted suicide, pornography, poverty, and political rights for cultural minorities? Theorists also ask whether respect for persons is the foundation of all other moral duties and rights or simply one important moral consideration among others, and whether non-Kantian ethical approaches such as utilitarianism can accommodate the idea that persons are unconditionally owed respect.

A rich debate concerns whether things other than persons, such as other living things or the natural environment, which are often valued merely as means serving human interests, have a moral status that demands respect. Some thinkers argue that the basis of morally required respect is wider than rationality and can be possessed by nonpersons. Others hold that there are levels of respect such that while persons are owed maximal respect, other things may be due a lower level of respect that nevertheless rules out certain treatment, such as destroying them for trivial reasons. Widespread acknowledgment of duties of respect to nonpersons could entail significant changes in many human activities, such as eating, land and energy use, and biomedical research.

Self-respect, important in its own right, involves due appreciation of one's morally significant worth: worth one has either as a person or in some position or activity (recognition self-respect), or worth earned through the quality of one's character and conduct (evaluative self-respect). Both kinds of self-respect include an engaged understanding of the implications of having worth for directing one's life and interacting with others. Respecting oneself contrasts with, among other things, servility,

acquiescence to disrespect, shamelessness, chronic irresponsibility, self-destruction, and self-contempt. Evaluative self-respect is distinguishable from self-esteem. The former involves regarding one's character and conduct as coming up to scratch; it is lost if one comes to regard oneself as morally intolerable. The latter is enhanced or diminished through believing that one has or lacks any highly prized quality.

Self-respect is regarded both as morally required and as essential to the individual's well-being. It is thus strong criticism to say that a person does what no self-respecting person would do or that a social institution undermines people's self-respect. For Kant, individuals have a moral duty to respect their equal dignity as persons and to do nothing that would degrade or disavow it. In *A Theory of Justice* (1971) John Rawls maintains that because the ability of individuals to respect themselves is significantly affected by their social and political circumstances and because self-respect is vital to individual well-being, justice requires that sociopolitical institutions support self-respect. Connections between self-respect and, for example, responsibility, self-identity, forgiveness, prostitution, oppression, and education are also of philosophical interest.

RESPONSE-DEPENDENCE THEORIES

The term *response-dependent* was introduced by Mark Johnston (1989) for concepts, such as *red*, that support an a priori biconditional on roughly the following lines: “X is red if, and only if, X is such that it would look red under normal conditions.” Any concept of the intended kind will apply to something just in case the object has a property in virtue of which it would elicit a relevant response, on a par with the appearance of redness, under relevantly favorable conditions; it will be akin to the concept of a secondary quality, traditionally conceived. The response to be elicited will involve a cognitive impression, so that the object looks, seems, or presents itself in a certain manner. And the conditions under which that response is guaranteed will have to be capable of independent specification; they cannot be defined just as whatever conditions will provide the guarantee.

Response-dependent concepts in this sense are meant to contrast with response-independent concepts whose application to an object depends solely on the nature of that thing in itself, not on the cognitive impression that the object makes on human beings. As Crispin Wright (1992) has emphasized in ongoing reflections around the theme, there must be a sense in which the object is of the conceptualized kind because it elicits that response, and not (or not just) the other way around; there must be a sense in which an object is red because it normally looks red.

The interest of the notion of response-dependence lies in the prospect of illuminating the character of a variety of concepts: for example, concepts of an evaluative, affective, or aesthetic kind; concepts associated with practices such as praise and blame or intervening causally in the world; concepts that are anthropocentric in any such manner; or perhaps all concepts that are mastered ostensively, without reliance on prior definition.

There are two very different theories of response-dependence in the literature. The biconditional associated with response-dependence, so all sides assume, does not hold because people’s relevant cognitive impressions never miss or misrepresent anything. So what makes certain concepts response-dependent, assuming that some concepts are indeed of this kind? What underpins the truth of the biconditional that governs them? The two theories diverge on that question.

One theory, explored by Johnston himself, would say that certain concepts are response-dependent because the

properties they designate are dispositions in things to evoke the relevant responses. Under this account we use a term like *red* to apply to those things that are such as to look red in suitable conditions; we think of the property of redness as the higher-order property of things that have a lower-order property, maybe this, maybe that, which makes them look red in suitable conditions. According to this theory, the concepts are response-dependent because the properties are defined by reference to responses; the a priori biconditionals hold, because they reflect the character of the properties conceptualized.

This theory has the disadvantage that, as Johnston (1993, 1998) himself has argued, few of our concepts are response-dispositional in this sense. With concepts such as *red*, we want to say that something looks red because it is red, where this is a causal explanation. But it is not clear that that claim remains available if redness is construed as a disposition; looking red will be a manifestation of the disposition, not a contingent effect. The issue has been a focus of controversy (Menzies and Petit 1993, Miller 2001).

The alternative theory of response-dependence would avoid this difficulty (Jackson and Petit 2002, Petit 2002). While allowing that there may be response-dispositional concepts, it says that other concepts may be governed by an a priori biconditional, too (or, being partly response-dependent, by at least an “only if” conditional). That will not be because they are paired with anthropocentric dispositions, but because the explanation of why they are paired with their particular, response-independent referents is that those properties have certain anthropocentric effects. On this account *red* may refer, not to the disposition to look red, but to a perfectly physical property, such as a certain profile of surface spectral reflectances. The reason why it will refer to that property is that it is the one that elicits the appearances on which speakers rely in learning to use the term. And so a connection will remain in place between the presence of the property and the looks-red response. Response-dependence will become salient, not at the level of semantics where we pair off terms with items in the world but, to invoke a distinction made by Robert Stalnaker (2004), at the level of meta-semantics where we try to explain the pairings that obtain between words and world.

Suppose that people generally rely on appearances in using the term *red*. Suppose that they intend to refer to a common, objective property in using the term; they are not content to go their idiosyncratic ways. And suppose

that because of that intention they seek to coordinate their usage, discounting some of the appearances of redness on which they divide. If this enterprise of coordination is to have objective significance, then there must be an objective reason for speakers to discount some appearances and not others; equivalently, there must be an objective reason to treat certain factors as perturbing or limiting influences on appearances. Why should speakers indict some influences as perturbing or limiting, then, but not others? According to this approach, it will be right to indict factors such that by privileging situations of usage where they are absent—by treating those conditions as favorable—speakers can optimally satisfy their joint intention to pick out the same objective property in things (Pettit 2002); the associated practice will do best in helping them to triangulate on a common, presumptively objective feature.

This approach will make it a priori, for any property such as redness that is available to be named in our language, that X counts as red if, and only if, it is such that it would look red under favorable conditions, with *favorable* defined by reference to the practice of discounting. The basis of the response-dependence will now lie, not in the nature of the property, but in the requirements that must be fulfilled for the property to deserve the name of *red*; that is why the biconditional is restricted to properties available to be named.

This theory of response-dependence allows us to say that while things may be conceptualized as red because of the associated appearances, still their redness is causally responsible for such appearances. It can mark out certain concepts as special, on a par with the concept of redness, particularly if the concepts are ineradicably response-dependent. And yet it can allow us at the same time to be realists about redness and similar properties, even holding that a term like *red* refers rigidly to an actual-world property (Haukioja 2001). If one wants to espouse response-dependence without too deep a revision of common sense, this is the way to go. If one aspires to be revisionary, the other theory of response-dependence is the better option.

Philip Pettit (2005)

RESPONSIBILITY, MORAL AND LEGAL

The term *responsibility* or one of its variants figures in moral discussion in many different ways. Philosophers have traditionally been especially interested in the concept of moral or personal responsibility. It is with the problems connected with this notion that the following discussion is primarily concerned.

JUDGMENTS OF PERSONAL RESPONSIBILITY

F. H. Bradley once claimed that "for practical purposes we need make no distinction between responsibility and liability to punishment." Although it is true that discussions of responsibility have often turned quickly to discussions of blameworthiness and liability to punishment, there is little justification for Bradley's claim. For responsibility is equally relevant to many other forms of social treatment—among others, praise, reward (including special honors such as honorary degrees or titles), legal punishment, legal liability. And, of course, the topic is intimately related to the theological issue of salvation, the allocation of divine rewards and punishments.

Judgments of personal responsibility pertain to this range of practices in a very special way. Unless a person is judged personally responsible for some act or outcome, he would not normally be thought to deserve blame, praise, reward, punishment, and so on. Personal responsibility is generally regarded as a necessary condition of the justice of a person's receiving what he deserves. Yet

Bradley's error is repeated in many contemporary discussions of "freedom and responsibility" that start with some unilluminating remarks about "responsibility," then move swiftly to examination of blame or punishment. Discussion of responsibility is theoretically fundamental, not ancillary, to accounts of such practices.

MEANING OF "MORAL RESPONSIBILITY"

Persons are normally judged morally responsible for their actions. But they may be judged responsible for almost anything—events, processes, their own psychological characteristics. Thus, a person may be judged morally responsible for his firm's loss of a contract, the Napoleonic wars, his bad temper, a technique for maintaining the fertility of land, or his friend's divorce. Under what conditions is a person responsible for one of his acts or for some other occurrence? If we can state the necessary and sufficient conditions for judgments of moral responsibility, we shall, in the process, be assigning a sense to the expression. "Moral responsibility," like so many other terms of moral discourse, is inevitably defined persuasively, for one is bound to be influenced in defining it by convictions about the requirements for deserved blame, praise, and so on. That is, one is bound to be influenced by convictions, explicit or implicit, about the requirements of justice in such matters.

Most persons, however, would accept the following form of definition, although those with different moral outlooks would complete it differently: A person is regarded as morally responsible for some act or occurrence *x* if and only if he is believed (1) to have done *x*, or to have brought *x* about; and (2) to have done it or brought it about freely. The completion of this formulation depends on what is meant by a human action; what would count as bringing some outcome about; and, above all, in what sense the terms *free*, *freely*, or *freedom* are employed. All these conceptions are problematic in ways that lead to very different theories of responsibility. Philosophers have too often supposed that the concept of "freedom" essential to moral responsibility can be fixed independently of what it is to be responsible, and that only after the meaning of *freedom* is specified can we determine whether, and under what conditions, a person is responsible. But in fact what a person means by *free*, *freely*, or *freedom* will reflect his moral convictions, and especially his views about justice, in the same way and for the same reasons that his conception of "moral responsibility" will reflect these views. As Harald Ofstad put it, "Ethical systems may determine the sense of 'freedom' we

select as relevant" (*Freedom of Decision*, p. 279). One need add only that they not only may, they do.

FREEDOM AND MORAL RESPONSIBILITY

In his *Nicomachean Ethics*, Aristotle tried to analyze the concept of "voluntary action." Nowhere in his discussion did he clearly take account of the problems that arise if all our decisions and actions are determined by circumstances beyond our control. But he did claim that actions are compulsory "when the cause is in the external circumstances and the agent contributes nothing." It is difficult to say whether, in this and other passages, Aristotle intended to claim that the fact that the cause of action is external implies that the agent contributes nothing and is therefore not free in the sense relevant to responsibility. But from the beginning of the Christian era, the view that if decisions and actions are so determined, then persons are not free in the relevant sense, has been forcefully advanced and denied by countless numbers of theologians and philosophers.

The earliest form of the controversy arose in the context of Christian doctrine. In particular the fourth-century Christian theologian Pelagius argued that the doctrines of original sin and grace, and of divine omnipotence and foreknowledge, led to morally repugnant conclusions, primarily the conclusion that although a person's tendencies, decisions, and actions are in no way the fault of the agent, he is nevertheless morally culpable for his actions and, in consequence, justly suffers the torments of hell. If these doctrines are true, Pelagius argued, God is not just. But as God is certainly just, these doctrines must be false. Pelagius insisted that man is possessed of free will in that he has the power of "contrary choice." This power makes it possible for men to sin. In the fifth century St. Augustine countered Pelagius's attack on orthodox doctrine with the claim that though God knows and wills all, he grants to each person who has faith freedom of choice. Though God knows what a man will do, he wills only hypothetical claims, of the form "If this man sins, then he *shall* be punished." Divine decrees of this kind are consistent with freedom of the will. But what about the possession of faith—is this in a man's power? St. Augustine insisted that it was; for to have faith is to believe, and "belief is simply consenting to the truth of what is said, and consent is necessarily an act of will. It follows that faith must be in our power."

Although the terms are often different, the issues generated by this exchange persist. The doctrine of scientific determinism, and not the doctrine of divine

omnipotence, is today more commonly thought to pose the chief difficulties. Scientific determinists maintain that external conditions specified in scientific laws are sufficient to produce each human choice and action. But the nature of free choice, the nature of human power and ability, the relevance of necessity to freedom, the role of choice and deliberation, the very possibility of human choice, and many other issues suggested by or actually crystallized in the debate between Pelagius and Augustine are still vigorously debated.

DILEMMA OF MORAL RESPONSIBILITY

Efforts to solve the problem of freedom of the will are conveniently considered against the background of the following dilemma.

If determinism is true, then all events, including any person's decisions and actions, are fully determined by circumstances that are ultimately beyond that person's control. If this is so, then that person could not have decided or acted differently. Hence the person was not free.

If determinism is false, then there are at least some events that are not fully determined by antecedent circumstances. To the extent that human decisions and actions are among those events which are not fully determined, those decisions and actions occur by pure chance. But what occurs by pure chance is not within a person's control. Therefore, to the extent that decision and action are not determined, the person is unfree.

But determinism is either true or false. Hence a person is never free with respect to decisions, actions, or the results of actions.

But, it is claimed, a person is morally responsible for an action or occurrence only if he is free in that respect.

Therefore, no one is ever morally responsible for any decision, action, or outcome.

FREEDOM AS THE LACK OF CONSTRAINT. Some philosophers have argued that determinism does not imply that a person's actions are beyond the person's control. They argue that there is a perfectly clear, ordinary sense to "being able" or "being free" to do something that is compatible with determinism. As Jonathan Edwards, the great American theologian, put it in *Freedom of the Will*, the most sustained, penetrating defense of this position: "Let the person come by his volition or choice how he will, yet, if he is able, and there is nothing in the way to

hinder his pursuing and executing his will, the man is fully and perfectly free, according to the primary and common notion of freedom" (Paul Ramsey, ed., 1957, p. 164). The central assumption of Edwards's argument is that the ordinary sense of statements like "Eisenhower could have ordered his troops to take Berlin before the Russians arrived" and "Kennedy was able to call off the invasion of Cuba, but he decided not to do so" is such that these statements are perfectly consistent with determinism. In David Hume's terms, there is an important distinction between an action being caused or determined by antecedent circumstances, and its being constrained or compelled or coerced by antecedent circumstances. Only when an action that is determined is also in some way constrained or compelled is the actor not morally responsible for that act.

Other philosophers have found this position unacceptable for a variety of reasons. Some have argued that the ordinary use of such expressions as "was free to," "could have," and "was able to" involves more than lack of constraint. They argue that careful analysis reveals that determinism is indeed inconsistent with statements of the form "X could have done such-and-such." Others have argued that freedom of the will depends upon freedom of decision, not freedom of action; and that if decisions are determined then it surely cannot be the case that one could have decided other than he did. Still others have claimed that there is no reason to accept the authority of common sense or ordinary language in these matters; that it is the philosopher's job to subject our common opinions to the test of careful, reasoned scrutiny, in the manner of Socrates.

MORAL JUDGMENTS AND RESPONSIBILITY. Among those who reject common sense as reflected in ordinary language as a basis for philosophical opinion are those who nevertheless endorse the distinction between constrained and unconstrained causally determined actions but defend it on explicitly moral grounds. Thus, certain philosophers have argued that the aim of holding someone morally responsible should be to influence future behavior in desirable ways—that, indeed, moral responsibility consists in the ability to be influenced by moral judgments. If a judgment of responsibility will not affect behavior in desirable ways, then there is no moral point in holding that person responsible. On this view, most customary excuses will still be acceptable. For it will not, in general, be possible to exert beneficial influence on a person if he did what he did either unintentionally or because no other course of action was possible.

One difficulty with this position is that we are, after all, concerned with persons other than the one whose responsibility is being judged. This concern can be accommodated by taking into account all of the consequences of a given judgment of moral responsibility, and determining whether the consequences are good, or best on the whole. But such a position seems to imply that a person believed to be innocent of an offense might be held morally responsible and be blamed or convicted on the general grounds that it would be socially beneficial to do so. And this seems to conflict with deeply held convictions about the requirements of justice in our commerce with other human beings. Considerations of this sort led Immanuel Kant to warn against the “serpent-windings” of utilitarianism. Utilitarianism seems to many to imply just such an unqualified appeal to social consequences.

Many thinkers feel that a related consideration has great importance in assigning moral responsibility. They have argued that the claims of justice are satisfied if we justify the rules according to which a person is judged to be morally responsible and blameworthy on the basis of the principle that social utility ought to be maximized, but then apply these rules to particular cases in a way that precludes any further appeal to this principle of utility. In this way, the claims of justice may be satisfied and the problem of freedom bypassed. This view, usually called “rule utilitarianism,” has been vigorously discussed by many contemporary moral philosophers. One criticism of it is that the restriction placed on the relevance of the principle of utility cannot itself be justified on utilitarian grounds, and that therefore the principles of justice cannot be explained or defended on a purely utilitarian basis.

FREEDOM AS SELF-DETERMINATION. Another gambit directed against the first argument of the dilemma rests on the distinction between self-determined action and action determined by circumstances external to the agent. Thus, Bradley argued that it is the self that may determine action and that, to the extent that this is so, the person is morally responsible for his actions. He argued that self-determinism does not imply that actions are predictable; actions are, in fact, not predictable, provided that the determining conditions are not entirely “materialistic” because they include “spiritual” or, perhaps, mental causes. The difference between the views of freedom as self-determination and freedom as absence of external constraint is that, although the latter allows that nonconstraining circumstances may be bodily causes external to the agent, the former view rules out this possibility. However, even if one could formulate a clear notion of the self that determines action, there seems to be no reason to

suppose that that self, or its determining characteristics, are themselves not determined by circumstances external to the agent. And if this is so, then the action would seem to be determined by circumstances that are ultimately beyond the person’s control. In reply to this objection it has been suggested that determinism does not imply that determinants occur before that which is determined—and that in the case of human decisions and action, the causal determinants occur simultaneously with the decision that in turn accounts for the action. Thus, the action is determined by a decision that is not itself the result of circumstances beyond the person’s control. For, as the determinants are concurrent conditions, in principle they can be affected by prior action. But it is not clear that this view rests on anything more than an ad hoc assumption needed to establish the possibility of self-determinism. There is, moreover, much psychological evidence for the view that if one’s decisions and actions are determined, then the determinants are circumstances temporally prior to them and external to the agent who decides and acts.

INDETERMINISM. Philosophers have been equally fertile in rebutting the second argument of the dilemma. Those who believe that only if determinism is false can a person be morally responsible, and thereby are impelled to attack this second argument, are usually called “libertarians” because they believe that the will itself is free in the sense of being undetermined. Libertarians claim that the fact that a decision or action is not fully determined by antecedent conditions does not imply that it occurred by “chance” or “accident” in a way that confers exemption from moral responsibility. But this argument does not refute the claim that an undetermined event is a matter of chance in a way that implies that it occurred by chance or by accident, in the sense of those terms that *is* relevant to moral responsibility. For example, the difference between knocking a flowerpot off a shelf as the result of the fully determined but accidental motion of someone’s arm or as a result of an undetermined motion of that arm seems irrelevant to a judgment of responsibility. The two events seem equally to void the responsibility of the agent. Both occurrences seem *accidental* in the relevant sense.

Others—J. D. Mabbott, for instance—claim that the first argument of the dilemma is sound, but it is inconceivable that moral responsibility is inapplicable to the human situation and, therefore, the second argument of the dilemma must be unsound. However, this is hardly an argument; it is rather a dogmatic affirmation of the point at issue. Still another argument is that human beings are so constituted that they necessarily hold others responsi-

ble for their actions and necessarily employ concepts in doing so that presuppose indeterminism. This conclusion would seem to rest on dubious psychological assumptions. In any event, if one could develop an account of moral responsibility that does not presuppose that determinism is false, which is morally defensible, and acceptance of which is psychologically possible, this view would be refuted.

HARD DETERMINISM. There have been other ingenious efforts to escape the toils of the dilemma. But it has also been argued that persons are indeed never morally responsible. According to this view, which has been called “hard determinism,” determinism is true and the first argument of the dilemma is sound. Hard determinists allow that blame and punishment may be useful, but they deny that they are ever morally deserved. Persons who blame or punish should do so only when engaged in moral education or social engineering; and blame and punishment have no special moral significance when they are justified as effective aids in these tasks. As the blame is not moral blame, there is no need to establish that it is deserved in virtue of the fact that the person is morally responsible. As John Hospers put it: “When we view other people’s frailties and shortcomings in the light of this perspective, we shall no longer say, ‘He deserves what he’s getting.’ Instead, we shall say, ‘There, but for the grace of God (and a favorable early environment) go I’” (*Human Conduct*, p. 521).

Hard determinists forget, however, that the claim that someone deserves what he is getting is not necessarily an expression of moral indignation. It may instead be an expression of the belief that all of the requirements of justice have been satisfied. If it is defensible to suppose that “freedom,” used in some sense consistent with determinism, is a requirement of justice, then hard determinism is unacceptable.

The general defect of the dilemma is that it presupposes that the relevant sense of “freedom” can be specified independently of a specific moral outlook, and particularly of a conception of justice. This defect reverses the proper order of moral reflection. The sense in which one can be said to have “acted freely,” and therefore to be morally or personally responsible and to deserve blame or praise or punishment or reward, should be specified in the light of one’s moral outlook—not independently of it.

LEGAL RESPONSIBILITY AND PUNISHMENT

Many philosophers regard the legal context as paradigmatic for the discussion of moral responsibility. It seems clear that the unfortunate tendency to identify moral responsibility with blame and punishment derives partly from this fact. Nevertheless, the assessment of legal responsibility is so closely related to the assessment of moral responsibility, and legal experts have given such sustained and imaginative attention to the task of articulating criteria that are applicable to complex cases, that a careful study of the relevant aspects of the law will certainly assist the development of an adequate account of moral responsibility. Though problems pertaining to responsibility occur in all branches of the law, criminal law has received the most attention; the topics most frequently discussed in this connection are *mens rea* and criminal insanity.

MENS REA. The doctrine of *mens rea* requires a certain “mental element” to have been present when the offense was committed. This mental element is usually, but misleadingly, described as “guilty mind.” The characterization is misleading, first, because it is generally supposed that the offender need not be aware that he is committing an offense (“ignorance of the law is no excuse”); and, second, because many advocates of *mens rea* do not even require that the offender be morally culpable. On this second point there is, in fact, considerable disagreement. Some argue that unless an offender is morally blameworthy for his offense, he does not deserve to be convicted. Others insist on the distinction between moral responsibility and moral blameworthiness, arguing that a person may be morally responsible and may deserve to be convicted and punished for a crime even though his actions were not blameworthy. Broadly speaking, then, those who subscribe to the doctrine of *mens rea* believe at least that only persons who are morally responsible for their offense deserve conviction and punishment.

Discussions of *mens rea* usually take for granted the possibility of resolving the philosophical perplexities described above. Certain assumptions, generally unexamined, are made, and the work of articulating criteria appropriate to the criminal law goes forward. Those who accept the doctrine of *mens rea* in any of its forms believe that the requirement is satisfied if the offender has committed his offense intentionally. Some also claim that unintentional actions that are performed recklessly or negligently involve the necessary mental element. In general, the person who commits an offense is thought to

have satisfied the doctrine of mens rea if he knew what he was doing at the time or if he would have known what he was doing had he proceeded with reasonable care and deliberation. The extent to which an offender is able to or actually does exercise deliberate control over his actions and their results seems to be central to the way in which moral responsibility as a condition of deserved conviction and punishment is incorporated into the criminal law. This point is, however, more general than the doctrine of mens rea itself—it being possible for someone to have acted intentionally while, by reason of mental defect, not possessing deliberate control over his actions. Before going on to this point, two criticisms of the doctrine of mens rea should be considered.

Objections to mens rea. There are those who argue that, at least for certain criminal offenses, the requirement of mens rea ought to be abandoned and that strict liability ought to prevail. That is, for certain offenses it does not matter that the act was unintentional and it does not matter that reasonable care was taken. There are various arguments for strict liability, but, in general, the case for it is specific to the offense.

Though the agent's state of mind would seem not to enter into legal deliberations where strict liability prevails, this is not quite so. For example, it has been held that a bank director is strictly liable for borrowing money in excessive amounts from his own bank. In *State v. Lindberg*, 258 U.S. 250 (1922), the director pleaded that he had been assured that the money borrowed did not come from his own bank. Though the director did not borrow the money from his bank intentionally, the act of borrowing was itself intentional. A person cannot be said to have borrowed money that he accepted as a gift; his own intentions as well as the intentions of the donor are controlling. Though borrowing does, therefore, require a certain state of mind, the absence of the "mental element" involved in intentionally borrowing from one's own bank would be sufficient to discharge a person from moral responsibility. Insofar as the doctrine of mens rea is designed to satisfy the requirement that only a person who is morally responsible for some act or its result deserves to be held legally responsible and punished, strict liability conflicts with it.

Criteria of mens rea. The second criticism does not so much repudiate the requirement of mens rea in establishing responsibility as it criticizes the effort to develop criteria for mens rea. H. L. A. Hart argued that the practical meaning of mens rea is given in what is allowed as excuse or mitigation within the law. In order to determine whether mens rea is established, Hart argues, "it is neces-

sary to refer back to the various defenses; and then these general words (like 'mistake,' 'accident,' and so on) assume merely the status of convenient but sometimes misleading summaries expressing the absence of all the various conditions referring to the agents' knowledge or will which eliminate or reduce responsibility." In other words the general "rules" summarize accepted excuses, and there just are no general principles in terms of which we can account for the acceptance of specific excuses. Hart then generalizes his discussion of mens rea to pertain equally to the assessment of responsibility in nonlegal contexts.

This thesis encounters many difficulties. For one thing Hart neglects to distinguish adequately between exemption from responsibility and exemption from blame or legal responsibility. Thus, if a person defends himself against moral criticism of his having hit someone else by claiming that he was acting in self-defense, he is in effect accepting responsibility but rejecting blame on the grounds that he was justified in what he did. Second, if proposed as a purely descriptive thesis about our actual use of the language of "excuses," Hart's position begs the prescriptive claim that a general rationale of excuse and mitigation ought to be given—that otherwise the acceptance of a certain excuse is morally arbitrary. Those who defend mens rea try to meet this obligation by focusing on the element of awareness of what we are doing when we choose and act. Indeed, Hart becomes his own best critic when, in a later essay, he argues that the main rationale for excuse and mitigation within law is respect for "the claims of the individual as such, or at least as a *choosing being*."

CRIMINAL INSANITY. A person might intend to kill a particular person after careful deliberation, and do so; and this would be sufficient to satisfy mens rea. But if the offender suffered from extravagant delusions of having been persecuted by the person killed, he would normally be thought to be entitled to exemption from criminal liability on grounds of insanity.

The criterion of legal insanity generally adopted within Anglo American law is the M'Naghten Rule. This rule was formulated by the judges of England in 1843 in response to the public outcry that resulted when Daniel M'Naghten was acquitted, on grounds of criminal insanity, of murdering Sir Robert Peel's private secretary. M'Naghten had mistaken the secretary for Peel and had killed that unfortunate man while suffering from persecutory delusions about Peel's intentions toward him. The judges attempted to provide a morally sound, legally workable criterion for determining whether a person was

entitled to acquittal on grounds of criminal insanity. They affirmed that:

to establish a defence on the ground of insanity it must be clearly proved that, at the time of committing the act, the party accused was laboring under such a defect of *reason*, from disease of the mind, as not to know the *nature and quality of the act he was doing*, or, if he did know it, that he did not *know he was doing what was wrong*. ... The question has generally been, whether the accused at the time of doing the act *knew the difference between right and wrong*. [Italics added.]

The rule has been the object of vigorous attack and defense ever since its formulation. One type of criticism roughly follows the line of argument expressed by various parts of the dilemma formulated earlier. For example, Barbara Wootton, arguing from a determinist position, claimed that no acceptable criterion of criminal insanity can be formulated; that efforts to formulate an adequate criterion of mental defect, and, in the final analysis, of responsibility itself, shatter on the rock of the first argument of the dilemma. Consequently, all efforts to assess moral responsibility should be abandoned within the criminal law. The law should be concerned solely with treating the offender. It is clear that this "reform theory" approach to the criminal law would sweep away not only the insanity plea, but *mens rea* as well. Thomas Szasz, by contrast, argued that there is no such thing as a mental illness, that the insanity plea is never a valid excuse, and that, therefore, it ought to be abandoned. This argument leads to the same conclusion on policy as that reached by the reform theorists with respect to the insanity plea, but leaves *mens rea* intact. Szasz is not skeptical of moral responsibility as such. Others, like David Bazelon (in his Isaac Ray Award Lecture, "Equal Justice for the Unequal"), criticize the M'Naghten Rule as being too narrow—as not embracing all those defects of mind that entitle an offender to exemption on grounds of not having been morally responsible for his offense. It seems clear that many of the issues generated by this debate, as well as those that concern the doctrine of *mens rea*, await an adequate philosophical theory of moral responsibility.

AN APPROACH TO A THEORY OF MORAL RESPONSIBILITY

An adequate theory of moral responsibility cannot identify moral responsibility with liability to blame or punishment. Moreover, any such theory must explicitly recognize what is, in any event, generally the case: that the

meaning assigned to the key concepts in the theory, particularly "freedom," reflects the moral outlook of its author.

The second point is of particular importance. Suppose one reflectively endorses a conception of justice according to which a person deserves blame or praise, reward or punishment, and so on, only if that person's decisions or actions are not determined. Then one should define "freedom" in such a way that "*P* decided (acted) freely" implies "*P*'s decision (action) was not determined." Correspondingly, suppose one endorses a conception of justice according to which a person deserves blame, and so on, only if his decisions or actions have some property that may or may not be causally determined by circumstances beyond his control. Then "freedom" ought to be defined in such a way that the meaning of "*P* decided (acted) freely" is consistent with determinism. It is our practical aims and interests that should govern the shape of our language, and not unreflected-upon linguistic habit that should govern the shape of our moral outlook.

Thus, a theory of justice is the essential foundation for a theory of moral responsibility. In this connection it should be remembered that just acts are not always right. (Would it be right to refrain from punishing an innocent person if the consequence was the destruction of human civilization?) Moreover, acts of blame, praise, reward, and punishment that are not just may sometimes be right. (One may be justified in blaming or praising an infant in order to influence his future behavior, but there would be no justice in it.)

Bibliography

Some of the more interesting classical and contemporary discussions (in a vast literature) are cited below.

GENERAL

For broad treatments of responsibility, see Harald Ofstad's *Freedom of Decision* (Oslo, 1960) and Austin Farrar's *The Freedom of the Will* (London: A. and C. Black, 1958). A number of important papers can be found in the anthologies *Free Will*, edited by Sidney Morgenbesser and James Walsh (Englewood Cliffs, NJ: Prentice-Hall, 1962); *Determinism and Freedom*, edited by Sidney Hook (New York: New York University Press, 1958); *Freedom and the Will*, edited by D. F. Pears (New York: St. Martin's Press,

1963); and *Freedom and Responsibility*, edited by Herbert Morris (Stanford, CA: Stanford University Press, 1961). The Morris collection contains many papers particularly relevant to legal responsibility and has an extensive bibliography. Historically, the most important work is Aristotle's *Nicomachean Ethics*.

DETERMINIST AND LIBERTARIAN DEFENSES

The best traditional defenses of the view that moral responsibility and determinism are compatible are Jonathan Edwards's *Freedom of the Will* (1754), edited by Paul Ramsey (New Haven, CT: Yale University Press, 1957), and David Hume's *An Enquiry concerning Human Understanding*, Ch. 8. Important contemporary statements of the same position have been made in C. L. Stevenson's *Ethics and Language* (New Haven, CT: Yale University Press, 1944), Ch. 14; Moritz Schlick's *Problems of Ethics* (Englewood Cliffs, NJ: Prentice-Hall, 1939), Ch. 7; and P. H. Nowell-Smith's *Ethics* (New York: Philosophical Library, 1957), Chs. 19–21.

The most influential recent defenses of the "libertarian" position are C. A. Campbell's "Is 'Free-Will' a Pseudo-Problem?," in *Mind* 60 (1951): 441–465, and Stuart Hampshire's *Thought and Action* (London: Chatto and Windus, 1959). See also J. D. Mabbott's "Free Will and Punishment," in *Contemporary British Philosophy*, edited by H. D. Lewis, 3rd series (London, 1956).

HARD DETERMINISM

For hard determinism, see Holbach's *Système de la nature* (London, 1770) and John Hospers, "Free Will and Psychoanalysis," in *A Modern Introduction to Philosophy*, edited by Paul Edwards and Arthur Pap, 2nd ed. (New York: Free Press, 1965), pp. 75–85. This volume contains an extensive bibliography of material bearing on the topic of the present entry on pp. 99–108.

ETHICAL THEORY

Some recent texts that place the problem of moral responsibility in the general context of an ethical theory are Richard Brandt, *Ethical Theory* (Englewood Cliffs, NJ: Prentice-Hall, 1959); A. C. Ewing, *Ethics* (London: English Universities Press, 1953); W. Frankena, *Ethics* (Englewood Cliffs, NJ: Prentice-Hall, 1963); and John Hospers, *Human Conduct* (New York: Harcourt Brace, 1961).

PROBLEMS IN THEORY-MAKING

Of the many technical articles dealing with various conceptual problems involved in the development of an adequate theory of moral responsibility, the following are of some interest.

On the difficulties of analyzing such terms as *can* and *ability*, see John Austin, "Ifs and Cans," in *Proceedings of the British Academy* 42 (1956): 109–132; Richard Taylor, "I Can," in *Philosophical Review* 59 (1960): 78–89, and A. S. Kaufman, "Ability," *Journal of Philosophy* 60 (September 12, 1963): 537–551.

On the difficulties of analyzing such terms as *intention* and *decision*, see Carl Ginet, "Can the Will Be Caused?," in *Philosophical Review* (1962): 49–52; Stuart Hampshire and H. L. A. Hart, "Decision, Intention, and Causality," in *Mind* 67 (1958): 1–12; G. E. M. Anscombe, *Intention* (Oxford: Blackwell, 1957), and A. S. Kaufman, "Practical Decision," in *Mind* 75 (1966): 25–44.

QUESTIONS IN CRIMINAL LAW

For works especially pertinent to the relevance of moral responsibility to the criminal law, see, in addition to the Morris collection (*Freedom and Responsibility*): J. D. J. Edwards, *Mens Rea in Statutory Offenses* (London, 1955); Joel Feinberg, "Problematic Responsibility in Law and Morals," *Philosophical Review* 71 (1962): 340–351; and G. L. Williams, *Criminal Law: The General Part* (London: Stevens, 1953), pp. 28–45, 77–81. See also Henry Hart's "The Aims of the Criminal Law," in *Law and Contemporary Problems* 23 (1958): 405–441, which presents a general defense of the claim that moral blameworthiness is an essential condition of criminal liability. For a contrary view, see H. L. A. Hart's "Legal Responsibility and Excuses," in Hook's collection, *Determinism and Freedom*; this article also in part constitutes an amendment to his own earlier essay, "The Ascription of Responsibility and Rights," *PAS* 59 (1949): 171–194, where he argues against the possibility of a general rationale of excuse and mitigation.

On the topic of strict liability, see R. A. Wasserstrom's "Strict Liability in the Criminal Law," *Stanford Law Review* 12 (1960): 730–745.

The literature dealing with criminal insanity is vast; see Barbara Wootton's *Social Science and Social Pathology* (London: Allen and Unwin, 1959), Ch. 8; Thomas Szasz's *Law, Liberty, and Psychiatry* (New York: Macmillan, 1963); David Bazelon's "Equal Justice for the Unequal" (The Isaac Ray Award Lecture). Unfortunately this last work is available only in mimeographed form.

Among scientific writings that have a special relevance are M. Gluckman, *The Judicial Process among the Barotse of Northern Rhodesia* (Manchester, U.K.: Manchester University Press, 1955), and B. F. Skinner, *Science and Human Behavior* (New York: Macmillan, 1953), Chs. 12 and 22.

Arnold S. Kaufman (1967)

REVELATION

The notion of "revelation" is central to three of the major world religions: Judaism, Christianity, and Islam. Through Christianity in particular it has long been an important element in the religious thought of the West, and the present entry will treat it in this context, especially that of Christian theology.

During the twentieth century, but beginning in the nineteenth century, many—especially Protestant—theologians radically revised their conception of revelation. The view that was virtually axiomatic for all schools of thought in the mid-nineteenth century and that still remains the majority position (for it continues both in Roman Catholicism and in sections of conservative Protestantism) may be called the prepositional view of revelation.

THE PROPOSITIONAL CONCEPT

In the propositional view, that which is revealed is a body of religious truths capable of being expressed in propositions. Because a knowledge of these truths is necessary for man's salvation, God has supernaturally made them known. Accordingly, in the words of the *Catholic Encyclopedia*, "Revelation may be defined as the communication of some truth by God to a rational creature through means which are beyond the ordinary course of nature" (Vol. XIII, p. 1).

The fuller significance of this propositional understanding of revelation appears when we view it in relation to three other basic theological categories with which it is closely connected. A particular conception of the nature of revelation involves a particular conception of the nature of faith, as man's response to revelation; of the Bible and its inspiration, as a medium of revelation; and of the character of theological thinking, as thought that proceeds on the basis of revelation.

When revelation is conceived as the divine disclosure of religious truths, faith is necessarily understood as the obedient believing of these truths. Thus faith was defined by the First Vatican Council (1870) as a supernatural virtue whereby "with the inspiration and help of God's grace, we believe that what he has revealed is true, not because its intrinsic truth is seen with the natural light of reason, but because of the authority of God who reveals it" (*Enchiridion Symbolorum*, edited by H. J. D. Denzinger, 29th ed., Freiburg, Germany, 1952, No. 1789).

The Bible finds its place in this system of thought as the book in which divinely imparted truths are written down and thereby made available to all humankind. Indeed, throughout considerable periods of Christian thought the Scriptures have been called the Word of God and have been virtually identified with revelation. The Bible is accordingly thought of as being ultimately of divine authorship; it has been written by human beings, but in the writing of it, their minds were directed by the Holy Spirit. Thus, the First Vatican Council said of the Scriptures that "because they were written as a result of the prompting of the Holy Spirit, they have God for their author" (*Deum habent auctorem*; Denzinger, *Enchiridion Symbolorum*, No. 1787); and in a similar vein, in the twentieth century, the Protestant evangelist Dr. Billy Graham said, "The Bible is a book written by God through thirty secretaries."

The propositional conception of revelation has also been integral to an understanding of the structure of theology that until recently has held unquestioned sway in

Christian thought since it was established by Thomas Aquinas in the thirteenth century. This hinges upon the distinction between natural and revealed theology. Natural theology comprises all those truths about God, and about the created universe in its relation to God, that can be arrived at by human reasoning without benefit of divine revelation. Accordingly, the core of natural theology consists in the traditional philosophical arguments for the existence of God. Revealed theology, on the other hand, comprises those truths about God, and about the created universe in its relation to God, that are not accessible to right reasoning as such and that can be known to men only because God has chosen to reveal them. (For example, it is held that while the existence of a supreme being is a tenet of natural theology, the further fact, stated in the Trinitarian dogma, that this being is "three Persons in one" belongs to revealed theology.) These various truths constitute the materials with which the theologian works, his primary task being to bring them together into a systematic body of doctrine.

These conceptions of faith, the Bible, and theology are linked together by the propositional character of revelation, with which they are all concerned. The revelation that is imparted by God, believed by men, published in the holy Scriptures, and systematized in the church's dogmas is a body of theological knowledge. This propositional conception of revelation began to form soon after the end of the New Testament period; reached its fullest development in medieval scholastic thought; was largely abandoned by the first Reformers in the sixteenth century, particularly Martin Luther, but became reestablished in the Protestant scholasticism of the seventeenth and eighteenth centuries; began to be questioned in the later nineteenth century; and was finally set aside by considerable sections of Protestant thought in the twentieth century.

THE HEILSGESCHICHTLICH CONCEPTION

The fundamental premise of the propositional view has no place in the nonpropositional conception of revelation that was widely adopted by Christian theologians in the twentieth century. This view maintains that revelation consists not in the promulgation of divinely guaranteed truths but in the performance of self-revealing divine acts within human history. The locus of revelation is not propositions but events, and its content is not a body of truths about God but "the living God" revealing himself in his actions toward man. The nonpropositional view thus centers upon what has come in recent theology to be

known as *Heilsgeschichte* (salvation history) identified as the medium of revelation.

It is not supposed that God has marked his presence by performing a series of miracles, if “miracle” is taken to mean an event that compels a religious response by eluding all natural explanations. It is not characteristic of those theologians who think of revelation in nonpropositional terms to regard the biblical miracles as constituting theistic proofs. Rather, the *Heilsgeschichte* is the way in which a certain segment of human history—beginning with the origins of the national life of Israel and ending with the birth of the Christian community as a response to Jesus—was experienced by men of faith and became understood and remembered as the story of God’s gracious dealings with his people. What Christianity (and, confining itself to the Old Testament, Judaism) refer to as the story of salvation is a particular stream of history that was interpreted by prophets and apostles in the light of a profound and consistent ethical monotheism. They saw God at work around them in events that accordingly possessed revelatory significance. The *Heilsgeschichte* is thus a portion of history seen “from the inside” by the illumination of a particular religious faith. The publicly observable series of events forming its basis belongs to secular world history and is capable of a variety of political, economic, psychological, and other analyses besides that of theistic faith. As a central instance of this capacity of history to be construed both nonreligiously and religiously, Jesus of Nazareth, who has been seen by those outside the Christian community in various ways—for example, as rabbi, prophet, or political revolutionary—is seen by Christian faith as the divine Son incarnate in a human life, seeking to draw men into a new life in relation to God.

Revelation, understood in this way, presupposes faith as its correlate. That God is at work in a certain situation, which accordingly serves a revelatory purpose, is always a judgment of religious faith. The part played by faith is thus integral to the total event of revelation, if we use “revelation” to refer to the completed communication that occurs when God’s approach has met with a human response. In the words of William Temple, whose formulation of this conception of revelation has become classic, “there is event and appreciation; and in the coincidence of these the revelation consists” (*Nature, Man and God*, p. 314).

As in the case of its older rival, the fuller significance of what may be called the *heilsgeschichtlich* conception of revelation can best be indicated by sketching its implications for the understanding of faith, the Bible, and theo-

logical thinking. Clearly, in this view faith is not primarily the believing of revealed propositions, but is rather (in its cognitive aspect) a mode of discernment or interpretation in which men are convinced that they are conscious of God at work in and through certain events of both their personal experiences and world history.

The Bible is not a collection of divine oracles, but a record of the events through which God has revealed himself to a special group, a record that itself functions as a further medium of God’s self-revelation beyond that group. It has not been written at the dictation of the Holy Spirit, but has been composed by many different writers at different points within the period of the thousand years or so that it documents. It is distinguished from secular records of the same sequence of events by the fact that it is written throughout from the standpoint of faith. The Old Testament is dominated and unified by the God-centered interpretation of Hebrew history taught by the great prophets, in the light of which the story of the nation came to be understood and celebrated and its chronicles edited. The New Testament is dominated and unified by the witness of Jesus’ first disciples and of the Christian communities that grew up around them to the life, death, and resurrection of Jesus, whom they had received as the Christ. The faith by which alone the several writers could produce this particular literature constitutes the “inspiration” that has presided over its production.

Finally, there is no body of divinely authoritative theological propositions. Religious doctrines are not revealed, but represent human—and therefore fallible—attempts to understand the religious significance and implications of the revelatory events depicted in the Scriptures. Theologians who regard revelation in this manner have generally abandoned the traditional natural theology, with its theistic proofs, and base their doctrines instead upon faith as it responds to the scriptural records.

SOME QUESTIONS

One of the questions that Christian theologians have repeatedly discussed is whether there is both general and special revelation. Are nature and history as a whole—including the whole religious history of humankind—revelatory of God, as well as the special occasions of the biblical *Heilsgeschichte*? Many theologians of all communions today hold that God is indeed universally active and that his activity always discloses something of his nature, even though his fullest personal self-revelation has occurred only in the person of Christ.

Another question that has at times been hotly disputed is whether there is an image of God (*imago dei*) in man that constitutes an innate capacity to respond to divine revelation (Emil Brunner) or whether, on the contrary, human nature is so totally corrupted by the Fall that in revealing himself to men God has to create in them a special capacity for response (Karl Barth).

The main philosophical question that arises concerns the criteria by which revelation claims may be judged. For proposition-centered religious thought the answer is provided by natural theology considered as a preamble to revelation. This establishes the existence of God and points, by means of miracles and fulfillments of ancient prophecy, to Christ and the Scriptures as the sources of revealed truth, supplemented in Roman Catholicism by the church as its divinely appointed guardian. For those theologies, on the other hand, that find God at work in historical events whose significance is discerned only by faith, there can be no proof of revelation. Such theologies arise within a community of faith (whether Jewish or Christian) that lives on the basis of what it believes to be an experience of divine revelation. It embodies in its life and literature the “memory” of momentous events in which God has opened a new and better life to humankind. The form of apologetic appropriate to this view is one that defends the right of the believer, as a rational being, given the distinctively religious experience out of which his faith has arisen, to trust that experience and to proceed to live upon the basis of it.

REVERSE MATHEMATICS

Reverse mathematics has its origins in Harvey Friedman’s 1974 address to the International Congress of Mathematicians. In it Friedman asked two fundamental questions: “What are the proper axioms to use in carrying out proofs of particular theorems, or bodies of theorems, in mathematics?” and “What are those formal systems which

isolate the essential properties needed to prove them?” Reverse mathematics was developed as an attempt to answer these questions, and since 1974 many logicians (especially Friedman and Stephen Simpson) have contributed to this project.

The goal in reverse mathematics is to find the minimal collection S of set theoretic axioms which suffices to prove a given theorem T . Because Zermelo-Frankel set theory is too powerful to provide this type of delicate analysis, second order arithmetic is used as the axiomatization of set theory. The formal language of second order arithmetic contains the symbols $+$, \cdot , $<$, 0 , 1 , \in , and $=$, as well as two types of variables: number variables (denoted by lower case letters and intended to range over natural numbers) and set variables (denoted by upper case letters and intended to range over sets of natural numbers). In this formalization, sets of numbers are referred to using the set variables, but there are no variables that range over sets of sets of numbers. Thus, unlike Zermelo-Frankel set theory, second order arithmetic has to treat collections of sets as formal classes. One potential point of confusion concerning second order arithmetic is that despite its name, it is not a form of full second order logic. Second order arithmetic uses first order predicate logic, but allows two distinguished kinds of variables to separate its notation for numbers from its notation for sets. Therefore, the usual tools of first order logic such as compactness and the Lowenheim-Skolem theorems apply to second order arithmetic and its subsystems. In particular, there are countable models of second order arithmetic.

The axioms for second order arithmetic fall into three categories. First, there is a finite number of axioms stating the basic relationships between $+$, \cdot , $<$, 0 , and 1 in the natural numbers. Two examples of these axioms are that for all m , $m + 0 = m$ and that for all m and n , $m \cdot (n + 1) = (m \cdot n) + m$. Technically these axioms are exactly the noninduction axioms from Peano arithmetic. Second, there is an induction axiom for sets which says that from the assumptions that 0 is an element of X and that for all n , if n is an element of X , then $n + 1$ is an element of X , we can conclude that every n is an element of X . This axiom captures the fundamental inductive nature of the natural numbers. Third, there is an infinite collection of axioms called the comprehension scheme. For each formula $\varphi(x)$ in the language of second order arithmetic (allowing additional free variables as parameters), there is an axiom stating that there exists a set whose members are exactly the numbers n for which $\varphi(n)$ holds. Because second order arithmetic does not allow the formation of sets of sets, these axioms do not give rise to a version of

Russell’s Paradox concerning the set of all sets which are not members of themselves.

The first step in analyzing a theorem T in reverse mathematics is to formalize the statement of T in second order arithmetic. This formalization can be done for most theorems in areas of mathematics that can be captured in some countable manner, such as classical geometry, number theory, real and complex analysis, countable algebra, and countable combinatorics. However, one of the limitations of using second order arithmetic as the underlying form of set theory is that it is not well suited to formalizing theorems from subjects such as general topology that depend heavily on the twentieth-century development of abstract set theory.

The second step is to find a subsystem S of second order arithmetic that is strong enough to prove T . This step often involves translating a classical proof of T into the formal system of second order arithmetic and letting S be the collection of axioms needed in the proof.

The third step is to show that T can prove each of the axioms in S over a suitably weak base theory (described below). This process of proving the axioms from the theorem is called a reversal, and it gives rise to the name reverse mathematics. If the system S contains axioms which are too powerful then the third step may be not possible. For example, a classical proof may use more axioms than are necessary. Therefore it is not uncommon to return to the second step and to try to find a different proof of T which uses weaker axioms. The third step is then repeated to see if these weaker axioms are provable from T . Once the third step is realized, the equivalence of the theorem T with the axioms S shows that S is a minimum collection of axioms which suffices to prove T .

Because the comprehension axioms (which state that for any formula $\varphi(x)$, there is a set whose elements are exactly the numbers n for which $\varphi(n)$ holds) are the only ones which explicitly state the existence of sets, the subsystem S is often formed by restricting the types of formulas allowed in this scheme. For example, the base theory over which one typically proves the reversals is denoted RCA and is called Recursive Comprehension Axiom.

Roughly, RCA restricts the comprehension scheme to those formulas which define sets whose membership can be calculated by a finite algorithmic procedure.

Many of the theorems analyzed in reverse mathematics as of this writing fall into one of five categories. They are either provable in RCA or equivalent to one of four standard subsystems: WKL (which is RCA plus an

axiom stating that every infinite binary branching tree has an infinite path); ACA (which allows sets to be defined by formulas that do not contain quantifiers ranging over sets, but may contain quantifiers ranging over numbers); ATR (which allows sets to be defined by transfinite recursion); and $\Pi_1^1\text{-CA}_0$. (which allows sets to be defined by formulas containing arbitrarily many quantifiers ranging over numbers and at most one quantifier ranging over sets). A small number of examples do not fit neatly into these systems, but there is little evidence that this number will not grow as more theorems are analyzed.

One of the philosophical applications of reverse mathematics is that it provides a general framework for showing the necessity of impredicative methods in particular areas of mathematics. (Roughly, a set A is predicative if it can be defined as the set of all numbers satisfying a predicate for which the truth value does not depend on the existence of A .) On the one hand, if a theorem T is equivalent to a set of axioms that contains impredicative axioms (such as $\Pi_1^1\text{-CA}_0$.) then T cannot be established without the use of impredicative methods. On the other hand, if T can be proved inside a system which contains only predicative axioms (such as ACA), then this proof shows that T constitutes a piece of predicative mathematics. Some of the other subsystems have similar foundational connections. For example, because RCA restricts comprehension to formulas defining sets whose membership can be decided by a finite algorithmic procedure, proofs in RCA have a number of similarities to constructive proofs. However, this analogy is not perfect because most varieties of constructivism differ sharply with RCA over the treatment of induction and over the law of excluded middle.

A second philosophical application of reverse mathematics is to give a partial realization of Hilbert's program. In order to eliminate concerns over set theoretic paradoxes and to establish the consistency of infinitary methods in mathematics, Hilbert tried to find two formal systems to capture mathematical reasoning. The first system would be foundationally secure but would only capture finitary reasoning. The second system would be large enough to encompass all of mathematics including the general methods of infinitary reasoning. His goal was to use the first system to show the consistency of the second system, thus justifying the use of infinitary methods once and for all. Gödel's Second Incompleteness Theorem is widely viewed as showing that Hilbert's program cannot succeed as it was originally conceived. However, it is still possible that a reasonable fragment of mathematics could

be developed within a formal system that could be shown to be relatively consistent in a finitistic formal system. Hilbert did not provide a strict definition for his notion of finitary, but it has been argued that the system of primitive recursive arithmetic satisfies his intuitive concept. Furthermore, since primitive recursive arithmetic can prove the relative consistency of WKL, the (substantial amount of) mathematics that can be developed in WKL is finitely reducible in Hilbert's sense and provides a partial realization of Hilbert's program.

RIBOT, THÉODULE ARMAND (1839–1916)

Théodule Armand Ribot, the French psychologist, was a professor of psychology at the Sorbonne and from 1889 was the director of the psychological laboratory at the Collège de France. A philosophical disciple of Hippolyte Taine and Herbert Spencer (whose *Principles of Psychology* he translated), Ribot, with Taine, initiated the study in France of a positivistic and physiologically oriented psychology. His interest in philosophy was inseparable from his interest in concrete psychological problems and persisted throughout his life. He founded and edited the *Revue philosophique de la France et de l'étranger*, one of the first French philosophical journals. Ribot influenced not only French positivists and physiological psycholo-

gists but even some thinkers who, like Henri Bergson, rejected his epiphenomenalism.

Ribot's work falls into three main periods, but he remained loyal throughout his life to the program expounded in the introduction to his first book, *La psychologie anglaise contemporaine* (Paris, 1870). He insisted that psychology must be liberated from "the yoke of metaphysics" and stressed the need for an empirical, biological approach to psychology and the limitations of an exclusive reliance on introspection. However, although he insisted on excluding metaphysics from the empirical sciences, he did not dismiss it altogether. The works of Ribot's first period were mainly expository and historical. *La psychologie anglaise contemporaine* surveyed English associationist psychology from David Hartley to Samuel Bailey. In *La psychologie allemande contemporaine* (Paris, 1879) he introduced the work of Gustav Fechner, Wilhelm Wundt, Hermann Helmholtz, and others to the French public. *La philosophie de Schopenhauer* (Paris, 1874) foreshadowed Ribot's later emphasis on the affective and instinctive basis of personality.

Ribot's second period, characterized by an interest in psychopathology, produced three classic works: *Les maladies de la mémoire* (Paris, 1881), *Les maladies de la volonté* (Paris, 1883), and *Les maladies de la personnalité* (Paris, 1885). Despite a wealth of clinical, empirical material, the underlying motive of these works was philosophical—a positivistic distrust of such reified abstractions as "memory," "will," and "self." These abstractions had played a prominent role in French speculative psychology and in Victor Cousin's eclectic idealism. Ribot showed that the simplicity of such abstract words hides the complexity of the phenomenon named, a complexity revealed by the dissociation found in mental diseases. Ribot was among the first to study dissociations of personality, and his law of regression—that amnesia affects the most recent and least organized impressions and reactions first—was a lasting contribution to psychology.

In Ribot's third period, which began with his *La psychologie de l'attention* (Paris, 1888), his interest shifted to normal psychological phenomena, particularly to affective phenomena. The major work of this period, *La psychologie des sentiments* (Paris, 1896), reflects Ribot's biological approach and his epiphenomenalism. Physiological drives underlie our elementary feelings of pleasure and pain, and more complex and evolved stages of these drives underlie more complex emotions. Organic sensibility evolved prior to consciousness, and feelings prior to intellect. Ribot's last work, *La vie inconsciente et les mou-*

vements (Paris, 1914), interpreted various manifestations of subconscious activity in terms of motor activity.

RICHARD OF MEDIAVILLA

(d. c. 1300)

Richard of Mediavilla, or Richard of Middleton, *doctor solidus*, was a Franciscan philosopher, theologian, and canon lawyer. Although his date of birth and country of origin are unknown, scholars are generally agreed that he was either French or English. We are certain that in 1283 he was appointed as one of the judges of the works of Peter John Olivi, and we possess three of his sermons, preached in Paris in 1281 and 1283. He was a master of theology in Paris during 1284–1285. In 1288, Richard was one of the tutors of the exiled Prince Louis, son of King Charles II of Sicily and later bishop of Toulouse. Richard's last writings seem to date around 1295, when he completed his commentary on the fourth book of the *Sentences* of Peter Lombard. After 1295 we lose all trace of Richard of Mediavilla.

Richard was a scholar in the tradition of Bonaventure and John Peckham. He seems to have had a flair for clear and orderly presentation and to have enjoyed wide popularity among his Franciscan confreres. Like many of his fellow Franciscans, he regarded Bishop Tempier's condemnation of 219 propositions in 1277 as definitive. As a result, he set himself to defend, clarify, and organize a philosophy and theology that would vindicate and establish the doctrines contrary to the condemned propositions. He differs from most of his fellow Franciscans, however, in that he is more sympathetic to the Thomistic theory of knowledge.

Richard was one of the first Franciscans to reject the Augustinian theory of divine illumination. For Richard our ideas are solely the result of abstraction from sensible things, though as universals they are strictly intramental. In metaphysics he held that being is predicated analogically, not univocally, of God and creatures. Because every effect somehow bears the trademark of the first cause, God's existence can be proved from the world of nature. Richard found the so-called a priori argument of Anselm unacceptable; he adopted Henry of Ghent's position that essence and existence are only intentionally, not really, distinct. His doctrine of universal hylomorphism—that is, that all creatures are composed of matter and form—coincides with that of Bonaventure. Richard's theory of one substantial form's consisting of multiple grades constitutes the most complete and well-ordered doctrine of the plurality of forms in the Middle Ages. Richard argues to the soul's spirituality from the immateriality of universal concepts. The faculties of intellect and will are not accidents of the soul, nor do they add to its essence; they merely constitute a new relation between the essence of the soul and its acts and objects. Liberty is formally in the will. In common with his Franciscan confreres, Richard asserted that the will is a more noble faculty than the intellect.

Conservative by nature, Richard of Mediavilla was not one to shrink from speaking out. In one remarkable statement we catch a glimpse of his spirit in the search for truth and goodness: "We must start a good war. It is better to fight against falsehood and malice with a certain amount of discord, than, by dissimulating, to give way to malice and falsehood for the sake of harmony" (*Quodlibeta* III, 22).

RICKERT, HEINRICH

(1863–1936)

Heinrich Rickert, the German neo-Kantian philosopher, was born in Danzig and received his degree in 1888 from the University of Strasbourg. In 1891 he began lecturing at Freiburg, succeeding Alois Riehl as professor in 1894. In 1916 he went to Heidelberg as successor to Wilhelm Windelband.

Rickert belonged to the southwestern school of neo-Kantianism. His main efforts were devoted to a study of the logical and epistemological foundations of the natural sciences and to the historical disciplines in the hope of arriving at a "unity of reality and values." He departed from Wilhelm Dilthey in his criticism of Dilthey's subjective approach to the understanding of historical reality and in his attempt to find a set of more objective criteria; his departure from Windelband consisted in rejecting Windelband's separation of natural and historical disciplines and offering instead a theory that considered all reality to be historical.

PHILOSOPHY AND NATURAL SCIENCE

In his early work, particularly in *Der Gegenstand der Erkenntnis* (Freiburg, 1892), Rickert raised the question of the relationship between philosophy and the natural sciences. He denied the universal validity of the method of the natural sciences and attempted to establish the primacy of practical reason as the foundation of his epistemology. He believed that only the Kantian critical method is adequate for explaining the epistemological presuppositions and limitations of the various sciences. While phenomenology may provide a method for describing the contents of consciousness, it fails to account for their intelligibility and relationship to objective reality. Hegelianism, on the other hand, in identifying the real with the rational, leaves out of account or distorts

the pluralistic character of reality. Only critical philosophy yields knowledge that is both universal and necessary; it alone can explain the pluralistic, dynamic, and yet rational character of society and history. In view of the lack of philosophical attention to the historical disciplines and because the then prominent philosophical problems of *Weltanschauung* seemed to hinge most directly on distinguishing scientific thinking from historical thinking, Rickert devoted himself thereafter primarily to the problem of historical conceptualization (*Begriffsbildung*).

INDIVIDUALIZING AND GENERALIZING THOUGHT

On the basis of Windelband's distinction between nomothetic (universal) and ideographic (particular) judgments, Rickert developed his logic of the historical disciplines. At both the scientific and the prescientific stages of conceptualization, he claimed, there are two ways of grasping reality: individualizing and generalizing. Individualizing thought is proper to historical thinking. Instead of fabricating a copy of a historical phenomenon in its complex totality, it establishes the essential relationships that bind the phenomenon to its environment and traces the various stages of its development. Philosophy studies the concept of development, while the objects of historical study are unique developments. Generalizing thought, therefore, is proper to the natural sciences but is inapplicable to history. "Reality," Rickert claimed, "becomes nature if we consider it in regard to what is general; it becomes history if we consider it in regard to the particular or individual" (*Kulturwissenschaft und Naturwissenschaft*, 5th ed., p. 63).

Historical method for Rickert is highly selective, and in the selection of data, value judgments are operative from the very outset. This being the case, the determination of value criteria (*Wertbegriffe*) becomes the primary concern of historical understanding. Generalizing thought is logically free of values (*wertfrei*) because it constructs universally valid concepts. The particular objects to which they apply are interchangeable, and each object, abstracted from all its other relationships, functions only to illustrate the general law. Although in generalizing thought a selective process is at work to determine the common character of a group of particulars, it is the common character, expressed in a formula, that is essential. The aim of generalizing thought is precisely to free its objects from relations of value (*Wertverbindungen*).

KULTURWISSENSCHAFT

Although history is a science of values, this does not mean that the historian may organize his inquiry arbitrarily; in that case history would be mere propaganda. In order for history to be objective, its values (state, law, art, religion) must be universal. The universality of historical values must be established epistemologically, and the relevance of the various social phenomena with respect to these values must be demonstrated empirically. Because history is written by, about, and for civilized men, social activity must be its subject matter. Since social activity can be grasped only by individualizing thought in terms of its significance for universal values, the historian's criterion must be culture, because social activity and value most nearly converge in culture. Culture is most directly concerned with the realization of universal values: "Culture is the common affair in the life of the nations; it is the possession with respect to the values of which the individuals sustain their significance in the recognition of all peoples, and the cultural values which adhere to this possession are therefore those which guide historical representation and conceptual formation in the selection of what is most essential" (*Die Grenzen der naturwissenschaftlichen Begriffsbildung*, 2nd ed., p. 509). Thus, believing that his method made of history a logically valid discipline that deals with objective reality, Rickert called the historical sciences *Kulturwissenschaft* (cultural science) in preference to Dilthey's term, *Geisteswissenschaft* (science of the mind or spirit).

UNIVERSAL HISTORY

Far from being a contradiction, universal history is not only possible but is the logical outcome of the search for the value principles (*Wertprinzipien*) according to which the historical process as a whole may be viewed. "The system of values provides the possibility of systematization, and the relationship [of history] to the system of values permits of individualizing treatment" ("Geschichtsphilosophie," p. 400). But precisely because the evaluation of the whole of history is involved, the system of value principles must be purely formal. "We would need something timeless in order to extract an objective sense from the temporal course of history" (*ibid.*, p. 418). Like Immanuel Kant, Rickert proposed three stages in the development of civilization: dogmatism, skepticism, and criticism, the last of which was the achievement of German idealistic philosophy. While this periodization cannot be verified empirically, it is an example of the critical approach to the question of the unity of historical development. Although it is purely theoretical, it nonetheless

gives an axiological grounding to the results of empirical research. In the last analysis, the problem of universal history is to introduce a method whereby the real and the ideal may be theoretically synthesized.

CRITICISM

The principal criticism brought against Rickert is that the introduction of a transcendental system of values is unhistorical and leads to the reification of existing values (*Wertabsolutierung*). In isolating universality by viewing it as a distinct realm of thought rather than as a function of all thought, Rickert actually confirmed the positivism and cultural relativism he had sought to overcome. In radically separating the universal from the particular, he was compelled to regard historical data as being identical with those of science, a series of discrete facts that differ only in the relationships in which they are observed. Nevertheless, the fruitfulness of Rickert's theory is borne out by his influence on such contemporaries as Ernst Troeltsch, Friedrich Meinecke, and Max Weber.

RICOEUR, PAUL

(1913–2005)

Paul Ricoeur is widely regarded as among the most important French philosophers of the twentieth century. He had contributed to most of the major philosophical movements from the 1940s to the present, including existentialism, phenomenology, hermeneutics, structuralism, critical theory, narrative theory, philosophy of religion, ethical theory, political philosophy, and philosophy of law. Ricoeur was a prolific author of twenty-seven books and more than 500 articles as of 2004. His works tend to focus on theories of interpretation and the philosophy of human nature, examining the limits on our ability to understand the world and to know ourselves. If there is a guiding thread that runs through Ricoeur's career it would be an attempt to develop a philosophical anthropology of human capability, in particular our capacities to act, understand, communicate, and be responsible.

Born in 1913 in Valence, France, Ricoeur studied classics and philosophy at the University of Rennes and at the Sorbonne. After holding a number of teaching positions in provincial colleges, he was drafted into the French army in 1940. He was soon captured and spent the next five years in a German prison camp. While in prison, Ricoeur translated Edmund Husserl's book *Ideas* (1913) into French and coauthored a study on Karl Jaspers with fellow inmate Mikel Dufrenne. After he was freed in 1945, Ricoeur taught at the University of Strasbourg (1948–1956), the Sorbonne (1956–1966), and the University of Paris, Nanterre (1966–1987). In 1970 he succeeded Paul Tillich as the John Nuveen Professor of Philosophical Theology at the University of Chicago where he held a joint appointment at the School of Theology and Department of Philosophy until his retirement in 1992. Ricoeur continued to publish works on hermeneutics, moral-political philosophy, and theology until his death in May 2005.

EXISTENTIAL-PHENOMENOLOGY

Ricoeur's early works were devoted to a phenomenological study of the human will. He sought to combine the

existentialist themes of Gabriel Marcel (incarnate existence) and Karl Jaspers (limit situations, such as birth, war, and death) with the methodological rigor of Husserlian phenomenology. The result is a proposed three-volume, systematic “philosophy of the will” that includes *Freedom and Nature: The Voluntary and the Involuntary* (1950), *Fallible Man* (1960), and *Symbolism of Evil* (1960). These works form the core of Ricoeur’s early philosophical anthropology. The third volume was to be on the “poetics of the will” but was never written.

In *Freedom and Nature*, Ricoeur employs the Husserlian method of eidetic analysis to the spheres of the will, affection, and volition. The goal is to describe the structures of voluntary action to uncover our fundamental possibilities of existence. Ricoeur retains from Husserl the central insight into the intentionality of consciousness and the methodological technique of bracketing, while recognizing that phenomenology must be supplemented with non-phenomenology given the limits placed on knowledge by the body. A phenomenology of action reveals the full extent to which consciousness is embodied and tied to involuntary functions, thus known both phenomenologically (as a subject of the will) and empirically (as an object for the will). The experience of our own bodies is never direct and unmediated; instead we interpret the involuntary aspects of our bodies as signs or symptoms for the will. These signs are read indirectly through one’s will as indications of the involuntary for the voluntary. We find consciousness in the body and the body in consciousness.

Ricoeur shows how the act of willing is both the realization of freedom and the reception of necessity. The act of willing has three moments, each inextricably related to the involuntary. The three parts are: 1) “I decide”; 2) “I move my body”; and 3) “I consent.” Each part has an object (or intentional correlate): A) the decision or project; B) the action or motion; C) the acquiescence or consent. Finally, each correlate is itself related to the different modes of the involuntary: a) motives, needs, values; b) skills, emotions, habits; c) character, unconscious, life. There is a fundamental reciprocity of voluntary decision, choice, and action with involuntary bodily functions, which act as a vehicle for the will. The involuntary necessity of the body both limits and enables human freedom. Yet the unity of mind and body, voluntary and involuntary, is never fully realized. Rather it is a regulative idea for understanding how humans are both free and constrained. Embodied freedom and unifying the will free from conflict is something we can only hope for but never completely realize. A poetics of the will in the proposed

third volume was to be Ricoeur’s attempt to show how imaginative and creative uses of language can suggest ways to reconcile the dualism of mind and body.

After having described the eidetic structures of the will as incarnate freedom, in the second volume of the philosophy of the will Ricoeur seeks to uncover the actual conditions of existence through an “empirics of the will.” One of Ricoeur’s aims is to overcome the tendency among existentialists to overvalue human transcendence and devalue human finitude. He believes that the mistake made by Jean-Paul Sartre and Martin Heidegger is to equate finitude (our inevitable and necessary limitations) with guilt (an undesirable experience of limitation). In *Fallible Man*, Ricoeur examines the conditions under which the will confronts its finitude and chooses evil and sin. The reason one chooses evil stems from the divided will. There is a disproportion between our finite limitations and infinite possibilities. This gap between our limited bios (our bodies, passions, and desires) and unlimited logos (our reason capable of grasping universals) renders us fragile and fallible. The fractured will, or fault in our existence (like a geological fault), opens the way for temptation, evil, and sin. We are not evil by nature but we have the capacity to be thanks to the disproportion in our will. Following Immanuel Kant, Ricoeur analyzes the existential significance of our fallibility in terms of imagination (the limits of knowledge), character (the limits of the will), and feeling (the limits of our emotion). The ineliminable conflict within human beings constitutes our capacity both for good and evil.

In the second volume of the empirics of the will, *The Symbolism of Evil*, Ricoeur continues to examine our capacity for evil by considering the various ways humans are already guilty, sinful, and fallen. He conducts a “phenomenology of confession” that describes the way we experience the transition from fallibility to fault (from our potential for evil to actually being evil). According to Ricoeur, confession arises from three sources: defilement, sin, and guilt. Defilement is interpreted as an objective state of impurity, sin as a social state, and guilt as a psychological interiorization of sin. Ricoeur then shows how this progressive “fallenness” is reproduced in four basic types of myth: myths of creation, myths of tragedy, myths of the fall, and myths of exile. Each type of myth is a symbolic expression of our experience of evil.

HERMENEUTICS

Through his analysis of myths, Ricoeur began to shift away from phenomenology to hermeneutics as he became more interested in the symbolic systems that

relate us to the world and impose an indirect or interpretive approach to knowledge and self-understanding. Symbols are double-meaning expressions with an apparent, first-order, meaning and a hidden, second-order, meaning. Symbols must be interpreted rather than merely perceived in order to be understood. Ricoeur contends that if language is taken to be the medium for thought and experience, it is impossible to realize a pre-linguistic and presuppositionless realm of consciousness. As a result, we can never have the kind of unmediated knowledge that phenomenologists have traditionally hoped to attain. As such, the mediation of self-understanding by signs, symbols, and language requires an interpretive, hermeneutic philosophy. Ricoeur often speaks of the detour self-understanding must take through language. The idea of a detour as a hermeneutical technique for reading signs of experience through something else is one of Ricoeur's favorite metaphors that reappears throughout his career.

In *Freud and Philosophy* (1965), Ricoeur develops a hermeneutic philosophy by contrasting Husserlian phenomenology and Freudian psychoanalysis. According to Ricoeur, Sigmund Freud introduces a model for understanding the relationship between experience and desire, as well as a technique for uncovering the relation of a latent, unconscious meaning to a manifest, conscious meaning. The unconscious is an interplay of language and desire that reveals and conceals, thus shaping and distorting how we understand ourselves and others. Freud removes the illusion of a subject that ostensibly is immediately transparent to itself, thereby frustrating the aim of phenomenology to describe experience faithfully. For Ricoeur, Freud's contribution to hermeneutics is a theory of interpretation geared toward unmasking and decoding symbolic expressions. Dreams and symbols are models of the complexity of language in which meanings are both given and hidden. This symbolic language requires an interpretation in terms of rules and law-like regularities to understand how it mediates experience. Psychoanalysis, on this account, is a hermeneutic technique for interpreting the semantics of desire, that is, the interrelations among language, experience, bodily desires, and culture.

In *Freud and Philosophy*, Ricoeur contrasts two opposing kinds of hermeneutics: the hermeneutics of belief and the hermeneutics of suspicion. The hermeneutics of belief is geared toward recovering and recollecting lost or forgotten meanings. Understanding a religious symbol involves a hermeneutics of belief because to understand its full meaning one must already have the

prior belief that it is sacred. The hermeneutic situation is that we must believe in order to know, yet know in order to believe.

By contrast, the hermeneutics of suspicion is geared toward unmasking, demystifying, and removing the illusions of symbols, which not only reveal but conceal meaning. Ricoeur draws on the "masters of suspicion," Karl Marx, Friedrich Nietzsche and Freud, each of whom posit a false consciousness in place of an immediate, self-transparent consciousness, and deception or delusion in place of the experience of participation. The hermeneutics of suspicion decipher meanings hidden and distorted by literal and apparent meanings. Ricoeur argues that self-understanding involves a dialectic of belief and suspicion: We must have a clear understanding of our past that is shaped by a projection of what we hope we can become.

In *The Conflict of Interpretations* (1969), Ricoeur further develops a hermeneutic philosophy through his confrontation with structuralist semiotics. Like psychoanalysis, structuralist semiotics calls into question the primacy of consciousness as the privileged, self-evident home of meaning. Ricoeur retains the insight of structuralists, such as Ferdinand de Saussure and Claude Lévi-Strauss, that language has objective characteristics best understood as an empirical science and that meaning is a function of a different agency than consciousness. Yet Ricoeur maintains this aspect of language without rejecting the fundamental intentionality of consciousness and role of the individual as a bearer of meaning. Language has expressive meanings that must be understood from the perspective of the first person as well as objective meanings that must be understood from the perspective of the third person. Ricoeur tries to integrate a structuralist method of objective explanation into an interpretive theory for understanding spoken and written language.

As a result of the confrontation with structuralism, Ricoeur develops a theory of language as discourse. In *Interpretation Theory* (1971), discourse is defined as a dialectic of event and meaning, sense and reference. Discourse takes place as an event but has an ideal, repeatable meaning that allows what is said to be repeated, identified, and said differently. As an event, discourse is referential (about something), self-referential (said by someone), temporal (said at some moment), and communicative (said to someone).

As a meaning, discourse is both what the speaker means and what the utterance means. The dialectic of event and meaning, sense and reference constitutes writ-

ten discourse as well. But where spoken discourse is addressed to someone, in a particular dialogical situation, written discourse is addressed to an indefinite number of absent readers. The task of hermeneutics is to understand the matter of the text that is autonomous with respect to the intentions of the author, its original addressee, and the context in which it was written. The matter of the text discloses a proposed world (of real and imaginary references) one could possibly experience, inhabit, verify, criticize, and so on. To appropriate the meaning of a text we must first let go and relinquish the illusion that subjectivity alone confers meaning. Now the text, not the symbol, is Ricoeur's model for the linguistic mediation of experience. Self-interpretation is mediated by textual interpretation; conversely, textual interpretation results in self-interpretation.

The hermeneutics of texts also applies to actions. In his article *The Model of the Text as Meaningful Action* (1971), Ricoeur argues that actions, like texts, are readable, with a meaning that is independent of the intentions of the actors and subject to conflicting interpretations. In the same way that a text becomes detached from its author, an action is detached from its agent and may take on unintended meanings of its own. The meaning of an action is then open to an indefinite number of interpretations by an indefinite number of possible readers.

Ricoeur believes that if human action can be read and interpreted like written works, then the methods and practices of textual interpretation can function as a paradigm for the interpretation of action for the social sciences. Ricoeur accepts Wilhelm Dilthey's distinction between two forms of inquiry: scientific explanation of the natural world, and historical understanding of the social world. Yet Ricoeur maintains that hermeneutics is a dialectic of explanation and understanding. Texts and actions have underlying structures to be explained as well as social meanings to be understood.

METAPHOR AND NARRATIVE

Throughout his career Ricoeur has examined how imaginative and creative uses of language improve our ability to express ourselves and extend our understanding of the world. Symbols, myths, metaphors, and fiction can capture experience in ways that ordinary, descriptive language cannot. Ricoeur maintains that the reference of creative language is divided or split, meaning that such writing points to aspects of the world can only be suggested and referred to indirectly. Creative language refers to such aspects of the world as if they were real and as if we could be there. In *The Rule of Metaphor* (1975),

Ricoeur develops his thesis that the split-reference of creative discourse discloses a possible way of being in the world that remains hidden from ordinary language and first-order reference. A metaphor is a heuristic fiction" that redescribes reality by referring to it in terms of something imaginative or fictitious, allowing us to learn something about reality from fiction. Heuristic fictions help us to perceive new relations and new connections among things, broadening our ability to express ourselves and understand ourselves.

Like all discourse, a metaphor is a communicative utterance that is produced as event, but understood as meaning. Yet, only a live metaphor is at the same time both event and meaning. A dead metaphor has lost its event character when it becomes a commonplace expression, such as, for example, to describe someone who is nervous as having butterflies in their stomach. A live metaphor contains a metaphorical twist that produces a new, surprising meaning. The meaning results from a tension in the way something is described metaphorically and how we normally understand it to be. In order to grasp the differences and resemblance that constitute a metaphor, we must see through the first-order, ostensive reference to the second-order, creative reference to understand how it relates the world. To understand what a metaphor means is to see that it is similar to and different from an ordinary description. The tension in a living metaphor between literal and imaginative must be preserved, not overcome, to be understood. Ricoeur argues that living metaphors create new interpretations that may potentially transform the way we understand and act.

In his three-volume *Time and Narrative* (1983, 1984, and 1985), Ricoeur continues to develop the themes of semantic innovation and the ability of poetic discourse to disclose new ways to see and to be in the world. The basic unit of a narrative is a plot, which unifies the elements of a story, including the reasons, motives, and actions of characters with events, accidents, and circumstances together into a coherent unity. A plot synthesizes, integrates, and schematizes actions, events, and, ultimately, time into a unified whole that says something new and different than the sum of its parts. The thesis of *Time and Narrative* is that connection exists between the temporal character of human experience and the act of narrating a story. Temporal experience is expressed in the form of a narrative, as a narrative is able to reflect our social reality because it expresses temporal experience.

The circularity of time and narrative is mediated by three senses of representation: *mimesis*₁, *mimesis*₂, and *mimesis*₃. *Mimesis*₁, or prefiguration, represents the aspect

of the imitation of action that draws on our pre-understanding of the difference between human action and physical activity. It has three aspects—structural, symbolic, and temporal—that form the cognitive and practical background that determines how we interpret human action. *Mimesis*₂, or configuration, is the pivot of the analysis of the relationship between time and narrative in which actions are configured into a story by means of a plot. An action becomes an event in relation to a plot of a story. In turn, a story is more than a succession of actions but rather the organization of events into an intelligible whole. *Mimesis*₃, or refiguration, refers to the act of reading that changes our practical understanding according to the configuration of the story. The act of telling and interpreting stories links narration with the practical transformation of the world. Hermeneutics for Ricoeur is now construed as the telling, writing, and understanding of fictional and nonfictional stories, in effect, linking time, narratives, and history.

In *Time and Narrative*, Ricoeur introduces the idea of a narrative identity. His thesis is that we understand a person's identity as we would a character in a fictional or historical narrative. One's self-identity is constituted by means of *emplotment*, which configures and synthesizes diverse and multiple elements of a life into a unified whole. Just as the story of a life unfolds like a narrative, the identity of a character also unfolds in a narrative. One's identity is constituted by the stories told about oneself, as well as the stories told by other significant figures in our lives such as parents, spouses, friends, and enemies. A personal identity is also tied to larger group identities, which, similar to a personal identity, are partly chosen, partly inherited, and constituted by the stories we tell about it. The identity of a group, culture, or nation requires that its members are convinced of the truth and rightness of their story. To be effective, these narratives have to shape how the members understand themselves as a part of the group. Ricoeur is particularly interested by stories of founding events that establish and sustain communities, and form our individual and group identities.

ETHICS AND POLITICS

Ricoeur is also interested in the role narratives play in moral deliberation. The ethical implications for personal or narrative identity is that an agent must maintain some kind of continuity of time in order to be accountable for one's actions. Identity is constitutive of accountability; narrative is constitutive of identity. In addition to attributing actions to agents, narrative discourse also attributes moral obligations to agents who have the

power to act and who are capable of being acted upon. Narration further mediates between description and prescription by providing a context and characters in ethical questioning. We tell stories as a part of the thought experiments we conduct, which allow us to test moral judgments in imaginary cases. Narration thus forms not only our moral ideals but also the stories we tell of ourselves and each other that help us determine if we have achieved it. How we individually and collectively remember events is crucial to the way we hold others accountable for their actions.

The fourth set of studies in *Oneself As Another* (1990), following the studies on speaking, acting, and narrating, form what Ricoeur ironically calls his "little ethics," an ambitious attempt to mediate between an Aristotelian, teleological conception of the ethical aim and a Kantian, deontological conception of the moral norm. Ricoeur's notion of practical wisdom incorporates the idea from the Aristotelian heritage that ethics is the practice of becoming a good person as a member of a political community. The good life consists in developing the virtues, habits, and practices that enable us to develop ourselves, sustain interpersonal relationships, and create a life of happiness together.

Ricoeur also incorporates the idea from the Kantian heritage that morality is defined by the obligation to respect universal moral norms. In this tradition, moral actions must be motivated solely out of duty to the moral law. Morality consists in obeying moral laws that are binding on everyone, respecting the dignity of other people, and acting as an autonomous member of a moral community. For Ricoeur, practical wisdom is the art of mediating the particular requirement of the ethical aim and the universal requirement of the moral norm geared toward acting appropriately and justly in order to achieve happiness with others in a good and just society.

In *Oneself As Another*, Ricoeur proposes three theses with respect to ethics and morality: 1) the primacy of ethics over morality; 2) the necessity that the ethical aim be mediated by the moral norm; 3) morality must seek recourse in ethics to resolve conflicts and aporias. Ethics encompasses morality—but while it is subordinate to ethics, morality is a necessary, deontological moment of the actualization of ethics. The final recourse to ethics (informed by morality) is a form of practical wisdom geared toward the appropriate application of universal norms in particular situations. The reason why ethics needs morality is to ensure that ethical life respects the autonomy and dignity of everyone.

The reason why morality needs ethics is twofold: 1) Without ethics morality would be empty; it is founded on and presupposes our desire to live well together with others; 2) When deontological norms produce conflicting obligation—as they inevitably do—we must refer back to the ethical aim of a particular good life in order to figure out what to do. Sometimes there is no right answer to moral problems. If moral judgment were simply a matter of balancing the ethical aim and moral norm, there would be no room for the tragedy of action, exemplified in stories similar to that of Sophocles's *Antigone*. It is in these intractable situations that the art of practical wisdom helps us make decisions and act justly and appropriately in the face of tragic situations.

Ricoeur's main contribution to political philosophy is his notion of the political paradox. He maintains that, on one hand, political authority is legitimate if it comes from the rational consent of the governed; on the other hand, political practice is often coercive, even violent, which is something, in principle, to which individuals cannot consent. The paradox of political authority is permanent. Ricoeur agrees with Hannah Arendt that it is necessary to distinguish legitimate power-in-common from illegitimate power-over, but he agrees with Max Weber that political institutions are in fact often characterized by domination. Consequently, we should recognize that political power and political discourse always teeters at the edge of violence and illegitimacy. The political sphere is a fragile balance between authority and force, reason and tradition, ideology and utopia.

In *The Just* (2000) Ricoeur argues that coping with political power is an exercise in practical wisdom, a mediation of our desire to live together in communities with the requirement of justice and the rule of law. Social justice not only requires democratic political and economic institutions that respect human rights, treat people equally, protect our liberties, and allow for full political participation, but it should aim to foster a good life for communities, emphasize the membership of citizens for whom political participation matters, and recognize the plurality of social goods and historic values that make us who we are.

Ricoeur's more recent work, *Memory, History, and Forgetting* (2004), examines the role memories play in our ability to represent the past and make present something that is absent. The first part is a meticulous phenomenology of memory, examining the object of memory, the act of remembering, and the nature of personal and collective memories. The second part is an epistemology of history that examines the documentary phase of archiving

eyewitnesses, the explanatory phase where historical explanations occur, and the representative phase where history takes its written or literary form. The third part is a hermeneutics of our historical conditions that examines the limits to our historical knowledge, the existential and temporal conditions of our historical knowledge, and the role of forgetting in relation to memory and history.

The work concludes with a plea for forgiveness as the best way to remember events in order to right past wrongs and to restore social bonds. Individual and groups must learn to remember events differently if they wish to achieve recognition and potentially reconcile. The political implications of memory involve policy considerations for the just allotment of memory to redress excesses of both memory and forgetting. Forgiveness, however, goes beyond justice and approaches the realms of charity and gift-giving. To ask for forgiveness is to recognize that a crime may be unforgivable. Yet, Ricoeur maintains that forgiveness is the best way to remember events to permit more hopeful futures together.

In the 1950s, Ricoeur rivaled Sartre in popularity in France. By the end of the 1960s his popularity waned, along with other phenomenologists, as a new generation of intellectuals dominated the French scene. Ricoeur spent much of the 1970s in the United States, writing in English and assimilating the work of Anglo-American philosophers. His French readers, however, were perplexed by his turn to analytic philosophy and, although his works continued to be read by theologians, his reputation suffered among philosophers. However, with the publication of the highly acclaimed *Time and Narrative* in the 1980s, Ricoeur was again recognized as among France's leading intellectuals. By then he had outlived and surpassed the generation of postmodernist philosophers from the late 1960s, taking his own creative, literary turn without ever abandoning his conviction that philosophy and reason are synonymous. Over his career, Ricoeur received honorary degrees from approximately forty universities, delivered the prestigious Gifford Lectures in 1986, and was awarded numerous significant international prizes, including the 2004 John W. Kluge Prize for Lifetime Achievement in the Human Sciences. After his retirement, he resided outside of Paris and continued to publish well into his nineties.

RIEHL, ALOIS

(1844–1924)

Alois Riehl, the Austrian neo-Kantian philosopher, was born in Bolzano. Riehl was consecutively Privatdozent (1870), extraordinary professor (1877), and professor (1878) at the University of Graz. He moved to the University of Freiburg in 1882, to Kiel in 1895, to Halle in 1898, and to Berlin in 1905.

Riehl's first philosophy was a realistic metaphysics based on Johann Friedrich Herbart and indirectly on Gottfried Wilhelm Leibniz, and it is of interest, just as in the case of Immanuel Kant, to study the relation between Riehl's precritical and critical writings. Between 1870 and 1872 Riehl made his first realistic, monistic, evolutionist decisions within that dogmatic framework. His *Realistische Grundzüge* (Graz, 1870) centered on the problem of sensation, which he originally conceived as a polycentric reciprocal matrix of consciousness and movement. In *Über Begriff und Form der Philosophie* (Berlin, 1872) he advocated a critical, rational requirement and the scientific character of philosophy, to which he assigned the historical task of leading to ideal ends. In *Moral und Dogma* (Vienna, 1872) he defended the independence of positive morality from beliefs.

A profound study of Kant freed Riehl from his metaphysical dogmatism. The first volume of his *Der philosophische Kritizismus* (1876) marked an important date in the history of the new Kantianism. This work highlighted the hold on Kant of the spirit of the new positive science (not so much through the influence of René Descartes as through that of John Locke and David Hume). Combating psychological and idealistic "misconceptions" of Kant's views, Riehl proposed that the evolution of Kant's thought be studied, and successive editions of *Der philosophische Kritizismus* benefited from previously unpublished writings of Kant discovered by Kant philologists. Kant, according to Riehl, clarified the method of philosophy; in abandoning metaphysics but not identifying itself with science, philosophy shows itself to be theory of knowledge and the methodology of the natural sciences. It is false, however, to eliminate the thing-in-itself and the presupposition of realism common to the sciences, as Hermann Cohen did. Kant distinguished form from content and sought to determine the formal a priori of nature in general and not the particular laws of nature evident in the real experience of the sciences.

In the second and third volumes of *Der philosophische Kritizismus* (1879 and 1887) Riehl reassessed and

amplified his own views. It was not easy: To do so he had to fight with Kant himself (whom Eugen Dühring had blamed for having "two centers of gravity"), even reduced to the first *Critique* alone. In Riehl's view, neither dogmatic realism nor idealism, whether phenomenalist, or absolute, or positivistic, was adequate. Riehl sought to bring Kant up to date concerning the "sensible and logical foundation of knowledge" by surveying the great scientific innovations since Kant's day, such as Robert Mayer's principle of the conservation of energy and the Darwinian theory of evolution. Only then could Riehl critically resume his own realistic monism centered on perception. But perception, the first cognition, is not, in Riehl's judgment, the first reality. The two aspects of perception—the mechanical, which can be made objective and is quantitatively determinable by positive science, and the qualitative, which is subjectively immediate and the sole revealer of the real universal reciprocity—are both phenomenon (*Erscheinung*), although not merely appearance (*Schein*); neither of the two aspects makes up "nature in itself." The monistic propensity, leading to the threshold of metaphysics, comes upon reefs the critique must steer clear of. For example, he desires that his identification of the physical and the psychical should not be confused with materialism, or monadism, or universal psychophysical correspondence, or Spinozistic panpsychism. Again, although Riehl saw mental life as a product of natural evolution, he denied the evolutionary genesis of logical and mathematical concepts.

In 1883, in his inaugural lecture at Freiburg, "Über wissenschaftliche und nichtwissenschaftliche Philosophie," Riehl turned to other fields of philosophy with a progressive valuation (compare a lecture at Princeton, 1913: "Der Beruf der Philosophie in der Gegenwart"). Even in *Der philosophische Kritizismus*, confined to the naturalistic horizon, he had apologized for glancing at "the field of practical philosophy" but had at the end intimated that beyond the realm of science lay the realms of moral action and artistic production (to which he later added religion). It may be asked whether there could be a philosophy of these things if "theoretical" is identical with "scientific" (*wissenschaftliche*). In his later years Riehl struggled with this problem, surrounded too by the other neo-Kantian movements. "Feeling," which he had acknowledged as another side of experience, might be available for that theoretical purpose, but to be so available its evaluations must be freed from practical empiricism. Heinrich Rickert, who had frequent contact with Riehl, later sought to show Riehl's increasing interest in the world of values, until Riehl finally acknowledged that

the role of philosophy is “to raise to conceptual clarity our knowledge of values and their system.”

RIGHTS

Although ancient ethics used the concepts of property and justice, each of which presupposes something similar to the concept of a right, the concept of a right in the modern sense developed only later. The first philosopher to define a moral right was most likely William of Ockham (c. 1285–1347), who noted that *jus* sometimes refers to the power to conform to right reason. Thus, he integrated the legal concept of dominium or property into the moral theory that the law of nature determines right action. Hugo Grotius (1583–1645) adopted the resulting

theory of natural rights—rights conferred by the law of nature—and made it the basis for his theory of international law. Hobbes and Locke used their conceptions of natural rights to explain the grounds and limits of political obligation. Hobbes (1588–1679) conceives of a right as a liberty of action that is the absence of any contrary obligation. Because the law of nature requires only that one seek peace, in a state of nature where there is no peace one has a natural right to do anything one desires. He infers that citizens can have a duty to obey the sovereign only if they give up most of their natural rights.

Locke (1632–1704), however, uses his theory of inalienable natural rights to limit the authority of the sovereign over the members of a society. He conceives of natural rights in the traditional way as powers of acting in conformity with the natural law and assumes that the law of nature also imposes obligations upon others not to prevent one from exercising these rights. The Lockean theory of inalienable and imprescriptible natural rights inspired the American *Declaration of Independence*, the French *Declaration of the Rights of Man and the Citizen*, and the subsequent development of constitutional law in much of Europe and North America.

Jeremy Bentham (1748–1832) subjected the doctrine of natural rights to severe criticism. The notion that there are natural rights—rights not created by human legislation—is conceptual nonsense because a right of one party implies a corresponding obligation of some second party, and an obligation exists only when commanded by some law enforced with coercive sanctions. Granting the existence of natural rights is morally perverse, for one could appeal to natural rights to justify any arbitrary action because without any law to define their content they would be indeterminate. Finally, the doctrine of inalienable and imprescriptible natural rights is politically dangerous because it would justify anarchy, for the individual’s absolute natural right to liberty or the pursuit of happiness could neither be given up by the citizen nor extinguished by coercive legislation. After the 1950s, few moral philosophers adopted a traditional natural rights theory because of skepticism about both the existence of a natural law expressing the will of God or a Cosmic Reason as well as one’s ability to know what it might command or forbid by the natural light of reason.

JURISTIC THEORIES

Skeptical as one may be of natural rights, one can hardly doubt the existence of legal rights. A central concern of modern jurisprudence has been to explain the nature of these rights. Although juristic theories are primarily the-

ories about the nature of legal rights, they can be extended to moral rights if one conceives of morality in terms of something like the moral law. John Austin held that a legal right is equivalent to a relative legal duty. Legal duties are imposed upon persons by laws that command some act or forbearance and constitute obligations because they are enforced by sanctions in the event of disobedience. Although some duties, such as the duty to pay one's taxes, are absolute in the sense that they are owed to society in general and not to any assignable individual, a relative duty is owed to one or more determinate second parties. Thus, the creditor's contractual right to be repaid by the debtor is simply the debtor's duty of repayment owed to the creditor viewed from the latter's point of view.

John Salmond (1920) developed the view of Rudolph von Jhering that a legal right is a legally protected interest. The object of any right is the thing—not necessarily a material object—in which the right holder has an interest. Not all of one's interests constitute legal rights, however. Only those protected by the law. For example, the object of one's legal right not to be killed is one's life, probably the most fundamental interest of every individual. This interest is protected by laws that prohibit killing and that punish murderers. Paul Vinogradoff (1928) maintained that there are three elements of any legal right. (1) A legal right must be claimed by some individual or state; (2) this claim must be recognized by organized society as justified from the public point of view; and (3), this declaration of right must be enforced by the legal authorities. Hence, a legal right is a legally protected claim. One's right not to be injured, and, if injured, to sue for damages, illustrates this conception of rights. Jhering and Vinogradoff set the stage for the ongoing contest between interest and will theories of rights. The former hold that the essential function of rights is to protect some interest of the right holder; the latter insist that the function of rights is to give the will of the right holder some privileged legal status.

Karl Llewellyn (1962) defined a right as a future judicial remedy. To say that Jones has a property right to his car is simply to predict how the courts will decide any cases concerning that car. For example, if someone steals the car, a court will hold that the vehicle shall be returned to Jones. Or if someone damages that car and Jones sues for damages, a court will decide in favor of Jones. This theory of rights reflects the rule skepticism of American legal realists. They argued that it is a mistake to identify the law with the general principles or rules written in the law books. What these general statements mean is left

open to the interpretation of the courts and may or may not be applied in practice depending upon how judges choose to decide particular cases. Hence, what the law really is consists of the decisions made by the courts.

Scandinavian legal realists are not rule skeptics. In fact, Alf Ross (1957) identified a legal right with a set of legal rules such that any one of a number of facts legally implies all of a variety of legal consequences. For example, if someone has purchased a thing *or* if someone has inherited a thing *or* if someone has earned a thing, then if another person steals that thing it shall be returned to the person who purchased or inherited or earned it, *and* if a second party damages that thing the second party shall compensate the person who purchased or inherited or earned that thing, and so on. What the legal right to ownership really amounts to is simply the preceding set of legal rules. Thus, the language of rights is a convenient technique of summing up a complex set of connections in the law. If legal rights seem to be some mysterious sort of ideal entities, this is merely because the language of rights has an emotive meaning that seems to give rights a magical power. This theory of rights reflects the concern of Scandinavian legal realists to reject the metaphysical idealism prevalent in continental legal philosophy.

Wesley Newcomb Hohfeld (1919) examined the writings of judges and jurists and concluded that they use "a right" indiscriminately to express any of four very different fundamental legal conceptions. This ambiguity suggests invalid legal reasoning because claims, liberties, powers, and immunities are different legal relations. A legal claim of X against Y is logically correlative with a corresponding legal duty of Y to X. For example, X's legal right not to be struck by Y is the logical correlative of Y's legal duty not to strike X. A legal liberty or privilege of X in the face of Y is simply the absence of any corresponding duty of X to Y. Thus to say that X has a legal liberty to phone Y after midnight is to deny that X has a legal duty not to phone Y after midnight. A legal power of X over Y is the ability to change some legal position of Y by some voluntary action of X. For example, X's power to give Y a book is X's ability to confer ownership of that book upon Y by handing it to Y and saying "I hereby give this book to you." A legal immunity of X against Y regarding some legal consequence C is Y's lack of legal power over X regarding C. Thus, X has a legal immunity against Y that Y not extinguish X's ownership of a book by Y's act of saying "I hereby take ownership of the book away from X." Hohfeld argued that in the strict sense, only legal claims are rights because an essential feature of the concept of a right is that rights and duties are logically cor-

relative. Every right implies a duty with a corresponding content, and every duty implies a corresponding right. He admitted that lawyers often speak of multiple sets of claims as a legal right, but insisted that clarity and precision require conceiving of a legal right as a single legal claim of one individual against one second party.

CONCEPTUAL ANALYSES

Joel Feinberg (1980) agreed with Hohfeld that rights are claims, but denied that rights and duties are logically correlative. Although every right implies some duty, not every duty implies any corresponding right. For example, one's legal duty to obey the orders of a police officer is imposed by the impersonal law and not owed to the officer. Similarly one's moral duty to sacrifice some of one's wealth to assist those in need does not imply any right of this or that needy individual to one's charity. Even when a right does imply some corresponding duty, it is a mistake to reduce the right to that duty. What is distinctive and most valuable about rights is that they put one in a position to claim and to demand—and not merely request or beg—performance of the duty owed to one. What confers this status of claimant upon the right holder is some set of rules—legal rules in the case of legal rights and moral principles for moral rights. Hence, a right is a valid claim, a claim justified by some appropriate set of rules.

H. J. McCloskey (1959, 1979) denied that rights are claims *against* and argued that they are entitlements *to* do, have, enjoy, or have done. Having purchased a car and obtained a driving license, one has a legal right to drive one's car. This is a right to do something—to drive on public thoroughfares; it is not primarily a claim against policemen and magistrates not to interfere. One possesses and exercises rights; one makes claims but does not possess or exercise them. Although one's moral right to life gives rise to duties of others not to kill one, it is primarily a right to live and preserve one's life. A hermit's right to life is the hermit's right to do whatever is necessary to sustain the hermit's life—including killing and eating animals—although there is no one else on or near the isolated island against whom the hermit could possibly claim the right to do so. Admittedly, the creditor's right to be repaid does hold against the debtor, but this is a special sort of right and not typical of rights in general.

H. L. A. Hart (1982) agreed with Hohfeld that “a legal right” is used to refer to four very different legal relations, but did not conclude that this makes the expression ambiguous. He explained what liberty-rights, claim-rights, power-rights, and immunity-rights have in com-

mon. They all consist of one or more bilateral liberties protected by a perimeter of duties. For example, at the center of one's liberty-right to look over one's garden fence at one's neighbor is one's legal liberty either to look over one's fence at one's neighbor or not to do so. This right does not impose upon one's neighbor any logically correlative legal duty to allow herself to be looked at; she is legally permitted to erect a higher fence or hide behind a screen. Still, this bilateral liberty is protected by a number of duties against interference. One's neighbor has legal duties not to climb over one's fence and assault one or to blind one with a chemical spray. What distinguishes one species of rights from another is the kind of bilateral liberties at their center. Thus, central to one's power-right to contract is one's liberty either to exercise one's legal power to accept an offer or to refrain from accepting it. And central to the creditor's claim-right to be repaid are the liberties to cancel or refuse to cancel the debt and, in the event of nonpayment, to sue or refrain from suing for payment. Thus, a legal right is an individual choice respected by the law. Presumably Hart thought of a moral right as an individual choice respected by the rules of morality. His view that moral rights concern the proper distribution of freedom strongly suggests some such theory.

Hart's respected choice theory of rights is a will theory of rights, but it is a mistake to assume that all will theories are option theories. Feinberg's claim theory of rights is also a will theory because he argues that to have a right is to be in a position to make a claim, to demand performance of some corresponding duty. Yet, his theory does not place any bilateral liberty at the center of every right. He even recognizes mandatory legal rights, such as the right to vote in Australia—where voting is a legal duty—so that one does not have any legal liberty to refrain from voting. As one would expect, Hart argued against interest theories of rights. For one thing, to hold that a right consists in an interest protected by a duty reduces rights to duties that benefit some second party. This renders the concept of a right redundant, for one can say everything one needs to say in the language of beneficial duties. But what is distinctive of rights correlative with duties are powers such as the right holder's power to cancel or enforce performance of that duty. Also, when a right benefits some third party, the right holder is not the party whose interest is protected by the law. Thus, when a parent purchases life insurance and names a child as beneficiary, it is the child's interest that is protected by the insurance company's legal duty to pay, but the right holder is the parent rather than the child.

Carl Wellman (1985, 1995) agreed with Hart that what is distinctive and important about rights is the way in which they allocate freedom and control upon the right holder. He defined a right as a complex of Hohfeldian positions that, if respected, confer dominion over some defining core upon the right holder in the face of one or more second parties. For example, at the core of the creditor's legal right to repayment is the creditor's legal claim against the debtor that the debtor repay the contracted amount at or before the due date. But Hohfeld was mistaken in identifying this legal right with a single legal claim. The creditor's claim would not hold against the debtor unless the right holder also had a legal immunity against the debtor's extinguishing the claim merely by saying "I hereby cancel my debt to you." And it also includes additional associated legal positions, such as the power to sue for repayment in the face of a recalcitrant debtor, the power to cancel the debt if one so chooses, and the legal liberties of exercising these powers. Although this is a modified version of Hart's will theory of rights, Wellman did not put a legal liberty—much less a liberty to choose—at the core of every right. The defining core of a legal right can be a legal claim, power, immunity, or even a liability. He also extended his dominion theory of rights to moral rights by arguing that there are moral liberties, claims, powers and immunities analogous to the legal relations Hohfeld identified.

Joseph Raz (1986) defined rights by their role in practical reasoning rather than in terms of Hohfeld's fundamental legal conceptions. It is a mistake to identify rights with interests, even protected interests, because rights serve as intermediate reasons linking interests to duties. At the same time, a right cannot be reduced to some correlative duty because a right is logically prior to any duty, and a single right can imply more than one duty or various duties under varying circumstances. To say that someone has a right is to say that—other things being equal—an aspect of an individual's well-being (one of that individual's interests) is a sufficient reason for holding some other person or persons to be under a duty. However, what makes one's interest of sufficient importance to ground duties need not be merely the value of that interest to oneself. For example, Abel's right to free speech is based on Abel's interest in speaking freely together with the public interest in allowing citizens to speak their minds without unjustified restrictions. Thus, rights are interest-based reasons for duties. This is an interest theory of rights, but more complex than the traditional protected interest theories of Jhering and Salmond.

Rex Martin (1993) rejected Feinberg's view that rights are valid claims. For one thing, not every right implies some corresponding duty as claim-rights do. The logical correlative of the constitutional right to free speech is a disability of Congress to enact statutes limiting speech. More importantly, moral or legal justification is not sufficient to establish a claim as a right. A slave's claim to freedom, no matter how thoroughly justified by moral principles, would be infirm as a right in any society where others could disregard it with impunity. Even if the slave's claim to freedom were justified by the legal rules of that society, it would be merely a nominal right if public officials, including judges, failed or refused to act in accordance with these rules. Real rights—moral rights as well as legal rights—presuppose the social practices of recognition and maintenance. Thus, rights are established ways of acting or being treated—for example, the civil right to the free exercise of one's religion or the moral right to be rescued from imminent danger. Because rights must be established by social practices, no right can exist independently of the institutions of a society. Thus, human rights are best understood as morally justified civil rights.

Judith Jarvis Thomson (1990) doubted that one can base a theory of rights on a definition of "a right" or general description of the nature of rights. Therefore, she used a conceptual analysis different from those previously described. She suggested that to attribute a right might be to talk about permissible and impermissible actions, but in a way which groups them to bring whole clusters of cases to bear on each other. Hence, to learn what the moral or legal significance of having some right is, one must discover the moral or legal consequences for the right holder and others of that right. For example, Jill has a moral right that Jack not break her nose. This implies—other things being equal—at least that Jack ought not to break Jill's nose, that it is morally permissible for Jill to defend herself against any attempt by Jack to break her nose, and that if Jack does break Jill's nose he ought to pay her medical expenses. Thus, Thomson analyzed rights in terms of what the right holder and others may or ought to do. This is an analysis resting upon the judgments of particular cases, not one derived from general principles.

POSSIBLE POSSESSORS

A conceptual analysis of rights usually implies something about the necessary conditions for the possession of any right. Thus, Hart's respected choice conception of rights implies that it is idle and misleading to ascribe rights to young children who have not yet developed the ability to

choose. Neil MacCormick (1982) suggested that children's rights are a test case for any theory of rights. He thought it clear that these children do have moral rights, including the rights to be nurtured, cared for, and if possible, loved. Because will theories cannot explain these rights, they must be rejected. In their place, he proposed a protected interest theory of rights. Because even neonates do have interests, this theory can explain how it is possible for them to be right holders.

Feinberg's theory also seems to imply that very young children could not be right holders. He maintained that to have a right is to be in a position to make a claim, to demand something as one's due. Infants seem incapable of claiming in this performative sense. But Feinberg believed that clearly even wee babies do make claims, not in their own persons but through parents or guardians who act as their representatives. These representatives are claiming on their behalf, acting in their interests. Because children do have interests from the day they are born, they are capable of being represented and, therefore, are possible holders of legal and moral rights. Thus, Feinberg combined a will theory of the nature of rights with an interest theory of possible right holders.

Feinberg extended his theory of possible right holders to the more controversial debate about animal rights. Because many non-human animals do have interests in food, shelter, and freedom from pain, human beings can represent them and make claims on their behalf. Hence, animals are also possible possessors of rights. R. G. Frey (1980) challenged the assumption that animals can have interests in the relevant sense. One can take an interest in something only if one can desire or want that thing, and this requires that one believe something about that thing. But because animals lack any language adequate for believing, they cannot possibly have the desires or wants presupposed by the interest theory of possible right holders.

H. J. McCloskey denied that it is the capacity to have interests that makes one a possible right holder because one may, on moral grounds, choose to exercise one's rights contrary to one's interests. The notion of exercising—acting on the basis of—one's rights is central to the concept of a right. And to exercise or refrain from exercising some moral right requires that one make a moral choice. Hence, it is the capacity for moral autonomy, for self-direction, and self-determination, that is required for the possession of rights. Because animals lack this capacity, they are not possible right holders. Robert Elliot (1987) agreed that the capacity to exercise one's rights is necessary for the possession of rights, yet denied that this

requires full moral autonomy—the ability to consider moral reasons and choose on those grounds. A human being could exercise one's moral right to self-defense simply by unreflectively defending oneself against an attacker. An animal could do the same. Hence, animals are capable of acting in a sense robust enough to enable them to possess rights.

Tom Regan (1983) accepted the Kantian view that human beings have moral rights because of their inherent value, but argued that it is arbitrary to restrict inherent value to moral agents. It is being the subject-of-a-life—having a life that goes better or worse for one—that confers inherent and not merely instrumental value upon one. Because at least the higher animals are also subjects-of-a-life, they are also moral right holders.

Are human fetuses capable of possessing human rights, including the right to life? Mary Anne Warren (1973) granted that unborn children are human in the genetic sense of being members of the same biological species as adult human beings, but denied that this is relevant to whether they are members of the moral community of right holders. It is because normal adult human beings are persons that they possess moral rights. The traits that are central to personhood are consciousness, rationality, self-motivated action, the capacity to communicate, and self-awareness. Although it may be uncertain how many of these and in what degree are required for personhood, it is clear that fetuses possess few of these traits in any significant degree. Therefore, a human fetus cannot possess any significant right to life.

Advocates of the right to life often argue that the human fetus has the capacity to develop into an adult person; this potentiality gives it the moral right to life. The standard reply to this argument is that the potentiality to become a person implies only the capacity to acquire rights in the future, not the capacity to possess them before birth. However, Francis C. Wade (1975) argued that if a kernel of seed corn has the capacity to grow into a stalk of corn, this must be because of something in the present nature of that kernel, an active tendency to grow. Similarly, the human fetus's potentiality of full humanity in the morally relevant sense is an active tendency to develop personhood already existing in the fetus. This explains how fetuses can now possess moral rights, including the human right to life.

MORAL RIGHTS

Although Bentham (1962) rejected the existence of moral rights independent of the law, John Stuart Mill (1969) defended their existence partly as moral grounds for

judging that some law is unjust. A duty is a kind of action that a person may rightfully be compelled to perform and that one may be punished for not performing. Legal duties ought to be enforced with legal sanctions; moral duties are obligations one should be compelled to perform by public opinion or the internal sanction of one's conscience. A moral right is the logical correlative of a relative moral duty, a duty owed to the right holder because that is the one who would be harmed by its nonperformance. Why ought society to defend one in the possession of one's moral rights? Mill's answer is that this will promote the general utility—the greatest well-being—of all the members of the society.

Ronald Dworkin (1977) argued that no utilitarian theory of rights can take moral rights seriously. Sometimes to say that someone has a right to do something is to say merely that to do so would not be to act wrongly, but to say that someone has a right in the strong sense is to assert that it would be wrong to prevent one from so acting. Thus, one may say that Jones has a moral right to spend his money gambling, although he ought to spend it in a more worthwhile way. The moral rights of the citizen against the state—such as the rights to free speech or to freedom from unreasonable searches—are worth taking seriously only if they are rights in the strong sense. If they were grounded on utility, the government would be justified in infringing them whenever it would be useful to do so. But this would undermine their moral purpose: to give the individual special protection against political interference. Therefore, a theory can take moral rights seriously only if it grounds them either on the human dignity of the individual person or on the ideal of political equality. Thus, the most fundamental moral right must be the right to equal concern and respect.

David Lyons (1994) responded that a utilitarian can take moral rights seriously. Dworkin failed to notice Mill's distinction between expediency and morality. An expedient act—one that has the best consequences—can be morally wrong because it violates a moral obligation. What makes an act a moral obligation is not its utility, but that society would be justified in imposing sanctions—either the disapproval of others or of one's own conscience—upon agents who fail or refuse to act. And enforcing moral obligations is justified by its social utility. For someone to have a moral right to something is for others to have a corresponding moral obligation at least not to injure and perhaps to promote the right holder's interest in that thing. This sort of indirect grounding of moral rights on the utility of the enforcement of the cor-

relative duties does not imply that a right may permissibly be violated whenever it would be expedient to do so.

L. W. Sumner (1987) agreed with Bentham that there are no natural rights, but did not infer that there are no moral rights. Although he rejected Hart's will theory of rights and held that the function of rights is to protect some interest of the right holder, he adopted Hart's view that rights presuppose social practice rules. Legal rules are made and upheld by the officials in some legal system; the rules of the moral code of a society are constituted by the practices of its members. But not every conventional right has moral force. A moral right is a morally justified conventional right, either an existing conventional right that it would be morally justified to retain or one that it would be justified to introduce into the conventional morality. And what justifies moral rights is the valuable consequences of maintaining the social practice rules that confer them upon moral agents. Although moral rights are grounded upon their contribution to human welfare, they can be taken seriously because the rules that confer them often constrain the direct pursuit of social utility.

Jeffrie G. Murphy (1977) argued that there are two very different kinds of moral rights. Autonomy rights mark out the special kind of treatment required to respect the dignity of autonomous rational persons. As Kant recognized, persons are ends—and not means only—and ought not to be sacrificed or used without their consent as instruments or resources for achieving the ends of others. Autonomy rights are grounded on the inherent moral value of autonomous rational agents. But Mill recognized a different function of moral rights: to pick out those moral claims that ought to be protected by society, especially by the law. However, Murphy rejected Mill's utilitarian justification of moral rights and argued that they are grounded on a hypothetical social contract of the sort described by John Rawls (1971). Thus, an individual has a social contract right to X only if a law guaranteeing X to the individual would be unanimously chosen by rational agents who are not aware of what their special circumstances would be in their society.

HUMAN RIGHTS

Although jurists usually identify human rights with the universal human rights recognized in international law, philosophers tend to view human rights as fundamental moral rights one possesses by virtue of being human. It is this latter sort of view that is most relevant here. Gregory Vlastos (1962) defined a just act as one prescribed exclusively by regard for the rights of all those it affects substantially. Although it is often just to distribute goods

unequally according to the merit of the recipients, equalitarian justice respects the equal human rights of everyone affected. Human rights are necessarily equal because they are grounded on the equal human worth of all persons, however different their individual merits. And what gives all human beings equal worth is the equal intrinsic value of their well-being and freedom. Hence, there are two classes of human rights: rights to goods required for human well-being and rights to fundamental human freedoms.

Alan Gewirth (1982) also grounded human rights upon freedom and well-being, but by a different argument. Human rights are primarily moral claim-rights of individual human beings that entail correlative moral duties of other individuals and organizations. All human beings are actual or potential agents, and human action consists in the voluntary pursuit of goals one values. Anyone who engages in action must presuppose that one has a right to the necessary conditions of prospective purposive action. And one cannot claim this and without self-contradiction deny that all other agents have the same rights. The two necessary conditions of human action are freedom and well-being. Hence, the various human rights to basic freedoms and goods are implied by the necessary presuppositions of human action.

James Griffin (2001) argued that the best account of human rights is one that preserves—but goes beyond the insights of—the traditional natural rights theories. It conceives of human rights as protections of personhood. Personhood should be understood in terms of the various strands of agency. These are autonomy (or making one's own decisions), forming a conception of the good life and being able to pursue it, and freedom from interference from others. Hence, there are three classes of human rights: autonomy rights, welfare rights, and liberty rights. The abstract human rights grounded on personhood are made more determinate by practicalities that spell out what is necessary, given the circumstances, to protect personhood. Thus, there are two grounds of human rights: personhood and practicalities.

Contemporary human rights documents reaffirm the traditional civil and political rights, such as the rights to life, free speech, and a fair trial. Yet they also assert social and economic rights, such as the rights to work, social security, and an adequate standard of living. Maurice Cranston (1967) argued that these supposed welfare rights are not genuine human rights. If they were universal human rights, they would impose upon every society the duties to provide employment, old-age pensions, and all necessary food and medical care for all their citizens.

But many societies lack the resources to provide such welfare benefits to all, and there can be no moral duty to do the impossible. Hence, there can be no human rights that would imply such duties. Civil and political rights, however, require only the appropriate legislation. James W. Nickel (1987) replied that civil and political rights also face the problem of scarce resources. No society can afford a police force adequate to secure the right to life of every citizen and the right to a fair trial can be real only where there is an expensive system of courts and adequate legal assistance for all. Moreover, there are ways to realize human welfare rights in societies with varying levels of affluence. A society can introduce programs to achieve progressively full employment or adequate medical care, prune a welfare right to achieve what is most important in it, or if necessary sacrifice more costly human rights in order to secure those that are affordable.

Cranston also insisted that a human right is something of which no one may be deprived without a grave affront to justice, but that it is not a grave injustice for human beings to lack old-age pensions or the medical care they need. Hence, social security and an adequate standard of living may be moral ideals, but they are not genuine human rights. Robert Nozick (1974) went even further and argued that there can be no basic welfare rights because their implementation would violate justice. Welfare rights would require programs such as Aid to Families with Dependent Children and Medicaid. But to fund these or similar programs, the state would have to tax the affluent and redistribute their wealth to the poor. This would be unjust because it would violate the human right to property of those whose wealth is taken from them without their consent. Nozick bases his argument on his entitlement theory of justice. John Rawls (1971), however, advanced a different theory of justice. According to Rawls, the morally justified principles of social justice are those that rational persons would unanimously choose were they in an original position of equality and unaware of their particular circumstances. He argued that one of these principles is that social and economic inequalities are to be arranged so that they are both (a) reasonably expected to be to everyone's advantage, and (b) attached to positions and offices open to all. This would require some redistribution of wealth to overcome great economic inequalities in a society.

Nozick also proposed a concept of rights that seems to exclude rights to welfare benefits. A moral right is a side-constraint on the pursuit of individual or social goals. For example, the right to property makes it morally wrong for one person to become wealthy by stealing from

anyone who owns something one desires, and the right to liberty implies that it would be morally wrong for the state to suppress opposition by imprisoning its critics. Moral rights reflect the Kantian idea that individuals are inviolable because they are ends in themselves and ought not to be used to achieve the goals of others. On this view, moral rights are negative; they constrain the actions of others by imposing only negative duties not to mistreat right holders in morally impermissible ways such as injuring them or interfering with their freedom of action. But any imagined welfare right would impose positive duties to provide welfare benefits such as old-age pensions or payments for medical care to individual right holders. There can be no human rights of this sort if fundamental moral rights are side-constraints that impose only negative duties.

Henry Shue (1980) rejected the view that the traditional civil and political rights are purely negative and that social and economic rights are positive. Every basic moral right imposes three sets of duties: duties to forbear from depriving right holders of the substance of their right, duties to protect right holders against the deprivation of the substance of their right, and duties to aid right holders in obtaining or regaining the substance of any right of which they have been deprived. For example, the basic right to liberty implies that the state has the duties not to imprison innocent persons, to protect individual persons from being kidnapped, and to aid anyone who has been unjustly imprisoned or kidnapped to obtain her release. Because some of these duties are negative and others positive, it is a mistake to argue that there cannot be any welfare rights, such as the right to subsistence benefits, simply because this would impose positive duties to aid those who lack the means of subsistence. As one would expect, the philosophy of rights remains as controversial today as it has been during the past few centuries.

RIGNANO, EUGENIO (1870–1931)

Eugenio Rignano was an Italian positivist philosopher and founder (1907) and lifelong editor of the scientific journal *Scientia*. Rignano's first works were sociologically oriented, but he later turned to biology and philosophical biology. His major work, *Psicologia del ragionamento* (1920), places the activity of memory at the basis of all biological and psychic phenomena. Memory is an activity that, through the specific accumulation of concepts, makes possible the progressive adaptation of the organism to the environment, the formation of instincts and emotions, and, in higher organisms, of reasoning. According to Rignano, reasoning is "a series of operations or experiences merely thought out simply"; in other words, a series of operations performed in imagination. The results of these operations are also imagined and are

assumed as the conclusions of the reasoning itself. This conception of reasoning, which Rignano derived chiefly from Ernst Mach, was later applied by him to explain the various kinds of reasoning: intuition, reduction, mathematical and mathematico-logical reasoning, intentional reasoning (dialectical or metaphysical reasoning), and pathological forms of reasoning as well. Rignano stressed the distinction between constructive and intentional reasoning. Constructive reasoning is motivated by a desire to discover the truth, and intentional reasoning by a desire to confirm a truth that a person believes he already possesses. Both types of reasoning utilize the same syllogistic form, but constructive reasoning is characteristic of the positivist scientist and intentional reasoning of the metaphysician. Rignano did not distinguish clearly between logical and psychological considerations; rather, he assumed the psychological mechanism as the basis of the logical validity of reasoning processes. The result is that Rignano's account is not very convincing either as logic or as psychology.

Despite his distaste for metaphysics, Rignano in subsequent works elaborated a kind of biological metaphysics based on the hypothesis that at the foundation of life and its evolution there is a "nervous energy" able to mold organic matter and direct it toward an increasing development and a growing adaptation to the environment. According to Rignano, life in its entirety shows a finalistic aspect that would be inexplicable if it were the product of physicochemical forces. This finalism can be explained, however, by assuming that life is a product of psychic, mnemonic energy, which on the basis of past experience envisions ends of future experience and adapts organic material to those ends. It is a kind of vitalism or animism that, according to Rignano, guarantees to evolution a progressive significance. The progress of evolution continues beyond organic life into moral life. The purpose of moral life is to guarantee to all individuals the satisfaction of their needs and to coordinate these needs in harmonious forms that gradually eliminate conflicts.

RILKE, RAINER MARIA (RENÉ) (1875–1926)

The German poet Rainer Maria (René) Rilke was born in Prague, the son of a minor railway official. His mother, who was of upper-middle-class origin, encouraged him in his early ambition to become a poet. The years 1886–1891, which Rilke spent at military academies in Moravia and Austria, had a traumatic effect on him, and not until 1920 was he able to come to terms with his unhappy childhood and family background. His first volume of poetry, *Leben und Lieder*, appeared in Prague in 1895. Desultory studies, mainly in the history of art, at the universities of Prague, Munich, and Berlin were followed by two journeys to Russia in 1899 and 1900 in the company of Lou Andreas-Salomé, a German-Russian to whom Friedrich Nietzsche had proposed marriage and who later became a follower and friend of Sigmund Freud. During the second of these journeys he met Lev Tolstoy. On his return Rilke joined an art colony in Worswede near Bremen, and early in 1901 he married the sculptress Clara Westhoff, one of its members. They had a daughter, but the short-lived marriage was only an interlude in Rilke's essentially solitary and unsettled life. For the next few years, Rilke's attention was centered on Paris and on Auguste Rodin, to whose work he devoted a monograph in 1903. Although his job as Rodin's private secretary ended in a quarrel, Rilke never ceased to acknowledge the very direct inspiration he received from close daily contact with the sculptor. The first collection of poems that bears the authentic stamp of greatness, *Neue Gedichte I* (Leipzig, 1907), represents Rilke's aim to render in words the immediacy, concreteness, and intensity ("the inward reality") that he discerned in Rodin's work.

With a single-mindedness that has rarely been paralleled in modern literature, Rilke devoted his whole existence to the poetic task he felt called upon to accomplish, subordinating to it all personal and public considerations. The long list of his patrons, most of whom belonged to the aristocracy of central Europe and a few to the German and Swiss patrician bourgeoisie, testifies to the restlessness of his life, and so do his journeys to Sweden (in 1904, on the invitation of Ellen Key), Italy, north Africa (1910–1911), Spain (1913), and repeatedly to France. The long list of his friends (mainly female) and correspondents, among them Paul Valéry and André Gide, includes surprisingly few German writers. Two places were of major importance for the fruition of his poetry: Duino (1910 and 1912), a castle on the Adriatic that belonged to the Princess Marie von Thurn und Taxis-Hohenlohe, where the first Duino Elegy was written, and the little castle of Muzot in the Swiss canton of Valais. It was at Muzot, in February 1922, as the guest of Werner Reinhart, that Rilke, in a storm of inspiration, wrote most of the fifty-five *Sonette an Orpheus* and several smaller collections of poems; and it was there, above all, that he completed his greatest work, which had been interrupted by World War I—the cycle of ten *Duineser Elegien*, several of which were written in the span of a few days. Rilke died at Valmont, Switzerland, after a protracted and painful illness that was diagnosed as leukemia.

Rilke's mature poetry, written after 1907, displays a consistency of attitude and a coherence of poetic devices that make it representative of a whole era of European thought. Following in the wake of Nietzsche, this poetry is informed by an acute historical consciousness. We live in an age when a "religion" that is based on separating transcendence from immanence is no longer viable:

All of the living
Make the mistake of drawing too sharp distinctions.
Angels (it is said) would be often unable to tell
Whether they moved among living or dead.

(FIRST ELEGY)

Our impoverished state is marked by our awareness that "we are not very reliably at home in the interpreted world." Hence, in order to regain for ourselves something that would equal the spiritual and existential fervor that characterized the ages of faith, we must take upon ourselves the task of endowing the world (which, for Rilke, is the world of things and of intimate personal relations) with the inwardness of feeling that other ages directed toward a divinity. Joy, love, and above all suffering and

pain should not be diffuse sensations accompanying an unending series of vague hopes and regrets; they must become the objects of a total commitment. Thus, since we are “not yet” strong enough to give ourselves totally in love, we had better follow the example of the lover (“Gaspara Stampa”) who drew her strength from an unrequited, “uninterrupted” feeling, or indeed of Narcissus, who used the natural world as a magnifying mirror of his feeling. *Les saltimbanques*, the traveling *artistes* of Pablo Picasso’s “blue period” paintings, celebrated in the Fifth Elegy, most fully symbolize our condition. In a world in which all actions are liable to remain uncompleted (“We, though, while we’re intent upon one thing, / can feel the cost and conquest of the other”), suffering—the fullest possible realization and appropriation by the self of what is inflicted from without—will be the greater virtue:

Killing merely is a form of our wandering sadness ...

Pure in the spirit serene

Is what we ourselves endure.

History, for Rilke, is not a social phenomenon but a pageant of situations and persons in whom the ideal of completion and strength of feeling was realized, just as the contemporary world is a series of images that portray our deprivations and stunted responses. To make something of one’s fate, of one’s experiences, is to give them the permanence (essentially poetic) of a moment of intensity. Similarly, the supreme task, set by the imminence of death, is to repair the adventitiousness of death by drawing it into my life, by making of it “my own death.”

The immensity of the task of creating a new spirituality is betrayed by the complex, and quite conscious, ambiguities of Rilke’s images of transcendence, chief of which is the image of the Angel, as he appears in the Elegies. He is a messenger (*angelos*) from another sphere; hence, there must be one who sent him. But the Angel comes upon us with a terrible majesty and strength which, to us who are weak, is all his own. In many such astonishing images Rilke expresses the “pure [=necessary] contradiction” that he sees as the root of our being: only by living in total commitment to “the Earth,” the here and now, can man transform it into “the heart’s inner space,” and thus wrest some eventual transition into a “soundless” Beyond—wrest it from he knows not whom. The most accomplished practitioner of such transformations is Orpheus, the poet-maker who, in the creative act, stills all strife by transforming it into song, eternalizes the moment by making of it a monument of inwardness, and

transfixes suffering into the eternally valid image of “Lament” (Tenth Elegy).

In a world yearning for the security of faith and finding it in ideology, Rilke’s vertiginous images were reduced to prosy precepts for living, becoming thus at once esoteric and banal. Rilke’s poetry is not necessarily esoteric, and the creative activity he extolled is closely related to the poetic; but he addressed himself to the single individual. The social sphere of modern life is branded as wholly inauthentic (Rilke either ignored or briefly satirized it); all concerted action is an escape from defective selfhood. He understood and expressed velleities supremely well; his poetry hardly offers a nostrum to cure them.

Bibliography

WORKS BY RILKE

Only the most recent four-volume edition, *Gesammelte Werke*, edited by Ernst Zinn (Frankfurt, 1955–1961), shows the magnitude of Rilke’s work. In addition, some eight collections of his letters are of major importance. The two-volume edition of *Selected Works* (London, 1954–1960) includes J. B. Leishman’s brilliant translations of all of Rilke’s major poetry.

WORKS ON RILKE

No English biography has appeared since E. M. Butler, *Rainer Maria Rilke* (Cambridge, U.K.: Cambridge University Press, 1941). H. E. Holthusen, *Rainer Maria Rilke in Selbstzeugnissen und Bilddokumenten* (Hamburg: Rowohlt, 1958), is a succinct and discriminating account of the poet’s life. See also N. Purtscher-Wydenbruck, *Rilke: Man and Poet* (London, 1949), and E. Buddeberg, *Rainer Maria Rilke—Eine innere Biographie* (Stuttgart: Metzler, 1955). A brilliant assessment of Nietzsche’s influence on Rilke is Chapter 5 of Erich Heller, *The Disinherited Mind* (Cambridge, U.K.: Bowes & Bowes, 1952). E. C. Mason has devoted many studies to a critique of Rilke’s work, among them *Lebenshaltung und Symbolik bei R. M. Rilke* (Weimar, Germany: H. Böhlau Nachf, 1939) and *Der Zopf des Münchhausen* (Einsiedeln, Germany, 1949). Two exegetic works of major importance are Jacob Steiner, *Rilke’s Duineser Elegien* (Bern: Francke, 1962), and Romano Guardini, *Rilke’s Duino Elegies: An Interpretation*, translated by K. G. Knight (London, 1961).

RINTELEN, FRITZ- JOACHIM VON (1898–1979)

Fritz-Joachim von Rintelen, the German philosopher of value, was born in Stettin. He received a doctorate in philosophy in 1924 from the University of Munich, where he began to lecture in 1928. Von Rintelen was appointed professor at the University of Bonn in 1933 and at Munich in 1936, but he was suspended on political grounds in 1941. In 1947 von Rintelen became professor of philosophy, psychology, and pedagogy at the University of Mainz. He was a visiting professor at the Universidad Nacional de Córdoba, Argentina, from 1951 to 1952 and at the University of Southern California in 1957.

Von Rintelen gave both a systematic and a detailed historical interpretation of the problem of value. Prior to his dismissal from his professorship at Munich, he had explicated in detail a theory of value (*Wert*) and of meaning (*Sinn*) and had built a philosophical anthropology upon it. After World War II he applied this theory to an analysis and penetrating criticism of the irrationalistic, nihilistic, and pessimistic currents in contemporary European philosophy and literature, showing how the theory resolves the conflicts and paradoxes that he reveals in these currents.

His doctrine of values and of personality is rooted in the realistic tradition of Platonism and Scholasticism but also shows the influence of German idealism. The chief direction of his thought was set in his two academic dissertations, a criticism of the pessimistic philosophy of religion of Eduard von Hartmann and an attempt to extend Ernst Troeltsch's efforts, in the later years of his life, to overcome historical relativism through a theory of values and their operation in history.

Two points in von Rintelen's criticism are particularly salient. The first is his attack upon all dualisms of intellect and will or of mind and life (Max Scheler), all subordination of the rational to a more inclusive irrational, and every combination of an idealistic theory of scientific knowledge with a realism in metaphysics. To these distinctions he opposes an ontological interpretation of value by which these dualistic tensions can be resolved. He rejects von Hartmann's teleology of self-destruction as an ontological impossibility and an aesthetic misreading of the tragedy of our culture; this tragedy cannot be denied, but it implies a transcendent normative meaning to be attained through the reflective transformation of our actions. Thus, there is an inclusive ontological meaning, not attainable through scientific

logic but through the value experiences of life, which sustains the human spirit and human life.

Von Rintelen's ontological theory of real value (*Realwert*) was constructed in opposition to psychological, positivistic, and phenomenological definitions. Real value is an objective context of meaning that can be particularized and made concrete through conscious or unconscious strivings. Each actualized value possesses an intrinsic worth varying in intensity with its degree of meaning and a relational worth by virtue of which it enters into a wider order of values. Thus every real value is vertically capable of degrees of normative validity and historically capable of individualization within larger contexts of culture and of personal action. Values are individualized in two spheres corresponding to life and mind in man. In the sphere of nature, objects are primarily existent and only secondarily valued; in that of mind or personality, objects are primarily mental and only secondarily grounded in concrete existence. From this viewpoint human history can be understood as a continually renewed effort to actualize values in terms of a personal regulative ideal of the highest possible fulfillment and in relation to an ultimate *summum bonum*, God, the unique, autonomous, and inclusive real value.

In 1932 von Rintelen published the first volume (ancient and medieval) of a historical study in which the development of this theory of value was to be traced in European thought. This work was left incomplete but was supplemented by specialized historical and systematic articles.

In his later critiques of existentialism and other contemporary intellectual currents, von Rintelen analyzed the plight of man as portrayed in modern philosophy and literature and, by correcting the subjectivism and finitism implicit in this portrayal through his own doctrine of value transcendence, points out the way to "a rewon security of spirit." Outstanding among these works are *Philosophie der Endlichkeit* (1951), which includes analyses of Martin Heidegger, Rainer Maria Rilke, Gabriel Marcel, and Jean-Paul Sartre, and *Der Rang des Geistes* (1955), a thorough and distinguished study of Johann Wolfgang von Goethe as philosopher, in which the inner tensions or polarities of the poet's thought are examined and Goethe's movement from an eclecticism to a rationally justified theism and an operative human ideal of rational freedom and love is portrayed. In these books von Rintelen shows himself not merely as a constructive philosopher but also as an able critic of literature and culture.

Von Rintelen's thought may thus be considered as a reconstruction of the Christian intellectual tradition in which the inevitable tragedy that inheres in the polarities of human existence may be overcome through a transcendent order of values in which meaning and impulse are harmonized.

Gedanken zur Philosophie von Fritz-Joachim von Rintelen," in *Sinn und Sein: Ein philosophisches Symposium F. J. v. Rintelen gewidmet*, edited by Richard Wisser (Tübingen: Niemeyer, 1960), pp. 611–708.

L. E. Loemker (1967)

Bibliography updated by Michael J. Farmer (2005)

RITSCHL, ALBRECHT BENJAMIN

(1822–1889)

Albrecht Benjamin Ritschl, the German theologian, was born in Berlin and studied theology at Bonn, Halle, Heidelberg, and Tübingen. He taught theology at Bonn from 1846 to 1864, and at Göttingen for the remainder of his career. Ritschl reexamined Christianity in the light of neo-Kantianism and historicist principles. After 1875 his influence was widespread in a number of German universities and led to increased interest in religious psychology, comparative religion, and related fields. However, his school came under sharp criticism from orthodox, pietist, and liberal quarters.

Ritschl undertook to establish Christian theology as an autonomous and systematic discipline. To do this he had first to purge German religious thought of pietism, Hegelian speculative theism, and the pantheism of Friedrich Schleiermacher and then to apply the techniques and results of contemporary literary and historical criticism. On the basis of Immanuel Kant's ascription of priority to practical reason over theoretical reason and his separation of philosophy and religion, Ritschl distinguished between value judgments and theoretical judgments. Unlike Kant, however, Ritschl accorded primacy to religion over philosophy on the grounds that spirit (the noumenal) takes precedence over matter (the phenomenal); also unlike Kant, he accorded moral primacy to the community (the nation) over the individual.

Ritschl believed that the deep-rootedness and continuity of religion, as expressed in dogmas and institutions, testifies to the reality and superiority of the religious need of practical reason in human nature. This need arises out of a basic contradiction between nature and spirit in human nature. The value of religion and particularly of Christianity, Ritschl thought, can be verified by history, which shows that this contradiction seeks a resolution in some form of redemption in the world. The Kantian elements in Ritschl's thinking, in combination with this positivist tendency, led him to believe that history does not merely provide material in support of some arbitrary, nonhistorical preconception but reveals an essential structure of human consciousness and the intrinsic historicity of Christianity.

In attempting to satisfy both the requirements of history and the claims of practical reason, Ritschl adopted the dogmas of redemption and the kingdom of God as embodied in the life of Christ as the pivots of his religious theory. Man seeks to realize his destiny here on earth by

leading an ethically self-conscious life, which is the core of religiosity. The acts of love that he performs, the content of the ethical life, represent the human counterpart to redemption, and the community required for their performance represents the terrestrial counterpart to the kingdom of God. God's purpose is thus manifest in history. Sin, which is only the result of ignorance, is pardonable because it is only a transitory opposition to this purpose. Ritschl therefore rejected the dogma of original sin as unhistorical and hence unverifiable.

Biblical exegesis led Ritschl to believe that the community is both logically and chronologically prior to the church. Only in the community can man find justification and reconciliation in God. Christ was founder of a community and can be comprehended historically only through our knowledge of how that community conceived him.

From his conviction that religious consciousness is universal and characterized by its quest for redemption, Ritschl concluded that Christianity is the superior expression of that consciousness. History, rather than dogma, verifies Christianity, but its validity is thereby strengthened, not relativized.

Although the community takes precedence over the individual, the individual is not thereby depreciated but is provided with a field within which he is able to realize his personality. While the community is prior to the church, this does not devalue the church's interests but emphasizes its actual efficacy as the ecclesiastical form of the community's organization. Religious truths are established in practice rather than by their appearance in the New Testament, but its authority is thereby strengthened, not subverted. Martin Luther is the most significant religious figure since Christ, not because he modernized Christianity but because he recaptured and restored an understanding of the original Christian attitude.

Robert Anchor (1967)

ROBINET, JEAN-BAPTISTE-RENÉ

(1735–1820)

Jean-Baptiste-René Robinet, the French *littérateur* and speculative philosopher, was born in Rennes. He started to become a Jesuit, but withdrew from the order and went to Holland to devote himself to letters. There he published his principal work, *De la nature* (4 vols., Amsterdam, 1761–1768), and in 1768, *Considérations philosophiques de la gradation naturelle des formes de l'être, ou les Essais de la nature qui apprend à faire l'homme* (2 vols., Amsterdam and Paris). He eked out an existence by hackwork, translating English novels and giving English lessons. He became embroiled with Voltaire by selling the manuscript of *Lettres secrètes* for publication without Voltaire's permission. He went to Paris in 1778 when he was made royal censor and secretary to one of the king's ministers. During the Revolution he returned to Rennes, where he lived quietly. In addition to many minor pieces, he published a translation of David Hume (*Essais de morale, ou Recherches sur les principes de la morale*, 1760) and edited a vast compilation, *Dictionnaire universel des sciences morale, économique, politique et diplomatique* (London, 1777–1783, 30 vols. in quarto).

De la nature caused some stir because of its strange ideas. When it was attributed to François-Vincent Toussaint, Denis Diderot, and Claude-Adrien Helvétius, Robi-

net admitted his authorship in a letter to the *Journal des savants*. The many quotations in *De la nature* testify to its author's vast readings; his thinking, however, is original. It is characterized by a curious mélange of mysticism and scientific spirit. *De la nature* touches on many subjects, but its announced theme is a modern version of Manichaeism: There is an equilibrium of good and evil in all substances and their modes. Robinet's purpose is to exculpate God and establish the necessity of evil. Embracing Benedict de Spinoza's principle that all possibles exist, he attacks Gottfried Wilhelm Leibniz by asserting that, therefore, there can be only one world and that God had no choice in the matter. "God no more had the power to modify the nature of the world than his own nature."

Robinet argued that behind the apparently random distribution of pleasure and suffering in the world there lies a fluid but fixed order. "The physical economy is such that good and evil are engendered with equal fecundity. They flow naturally from the depth of essences." God can in no way remove evil, for omnipotence does not extend to impossibles or contradictions. The suppression of evil implies contradiction, for good without evil would be infinite. The total quantity of good and evil is at every moment equal. Thus the harmony of the world is always the same, and progress is a myth or an illusion. Despite this equilibrium, God is good and his justice is seen in his not having favored one species at the expense of the others; for man is not king of the universe, as Buffon had claimed, and nothing has been created especially for his use. For human beings, life is a balance of happiness and unhappiness, and they should therefore console themselves by the enjoyment of pleasures. Moderation is the best path in all areas of life. The lower classes must be kept in ignorance, for their own benefit and that of the state; slavery is justifiable. Human nature being what it is, equality and fraternity are impossible.

The universe, for Robinet, is animate. All forms of being, including planets and stars, have the power of reproduction. The individual is unimportant, an instrument nature uses for its procreative purposes; only the species endures. Robinet speculates that nature has developed variations on a single prototype; from stones to men, there is a natural gradation of beings. The "prototype" is "a germ which tends naturally to develop itself.... Its energy cannot be repressed.... The germ develops, then, and each degree of development gives a variation of the prototype, a new combination of the original plan." The only difference between stone, plant, and animal is "the measure in which they participate in that essence.... A stone, an oak, a horse are not men; but they can be

regarded as more or less rough types in their relation to a single primitive design." We must consider the succession of individuals "as so many steps of being [advancing] toward humanity."

Robinet draws close to an evolutionary hypothesis in his concept of nature as experimenting and as developing toward greater complexity; he also considers all species as related. It is not a true evolutionism, however, inasmuch as each trial in the ascending scale of complexity is made de novo from the relatively unorganized stage of the original prototype. Species do not themselves have a history but are fixed once they are spewed forth. Robinet also pictures a biological struggle for existence and a natural balance, but does not relate these to transformism. Robinet's work influenced both Johann Gottfried Herder and G. W. F. Hegel and was considered of interest in the former Soviet Union.

ROHAULT, JACQUES (1620–1672)

Jacques Rohault was a mechanistic Cartesian experimental physicist. He was born in Amiens, France, and earned his MA in Paris in 1641. There, he became Claude Clerselier's Cartesian disciple and son-in-law. He was Pierre-Sylvain Régis's teacher and converted him to Cartesianism. In the 1650s Rohault was a private tutor in Paris, and his "Cartesian Wednesday" evening lectures, complete with laboratory table demonstrations, were

attended by many members of the noble class, women as well as men, and did a great deal toward popularizing Cartesianism. His *Traite de physique* (Paris, 1671) was a standard text for nearly fifty years. John Clarke and Samuel Clarke, rather than writing a Newtonian physics, translated Rohault's work into Latin (1697) and English (1723) and added Newtonian footnotes to correct Rohault's Cartesian mistakes. The *Traite* contains descriptions of explanations and experiments in support of Cartesian mechanistic physics. Like René Descartes, Rohault holds that these explanations are only probable because absolute certainty is unattainable by humans.

Also in Paris in 1671 Rohault published his *Entretiens sur la philosophie*, in which he defends the thesis that Cartesian principles and Christian doctrines do not conflict because each pertains to a separate and distinct realm of truth and knowledge. The book was popular, but Rohault's position was generally viewed as heretical by the Catholic Church.

Rohault opposes Nicolas Malebranche's occasionalism and presents his own mechanistic Cartesianism based on eight axioms he takes to be self-evident:

- (1) Nothing (that which has no existence) has no properties
- (2) Something cannot possibly be made of nothing, that is, nothing cannot become something
- (3) No thing or substance can be annihilated, that is, something cannot be reduced to nothing
- (4) Every effect presupposes some cause
- (5) If one does not cause an effect, that effect necessarily depends on some other cause
- (6) Everything endeavors to continue in the state in which it is (an early Cartesian rendering of a principle of inertia)
- (7) Every alteration is made by some external cause, that is, in opposition to Aristotle, no material thing can alter itself through an inner power, force, or form
- (8) Every alteration is proportional to the force of the causal agent

Certain propositions follow logically from these axioms, but Rohault says these truths of reason remain purely formal and have no application if there are no existents. Thus, the first task in understanding the world is to seek out existents. In strict Cartesian order one knows first one's own self, whose existence Rohault proves syllogistically:

- (a) From principle (1) above, whatever has properties is something
- (b) Thinking is a property
- (c) Whatever thinks, therefore, exists as something because it has the property of thinking
- (d) I think
- (e) Therefore, I exist

Reasoning with these principles about ideas and sensations leads to knowledge of the essences of mind, God, and matter and to proofs of the existence of God and of matter. The essence of mind is thought; of God, necessary existence; and of matter, extension. Rohault states that mind and matter are completely different but that God so created the human mind or soul such that motions caused by material impressions on the sense organs and in the brain of the body with which it is united give rise in the soul to sensations and ideas. Neither sensations nor ideas resemble material things, and so resemblance is not necessary for knowledge. It is simply the nature of sensations to give knowledge of the existence of material things, and the nature of some ideas is to give knowledge of the place, situation, distance, magnitude, figure, number, and motion or rest of material things.

Rohault's method in physics is to reason mathematically about experiments before conducting them. His goal is to explain the sensible effects of material things. For this only the primary material properties of size, figure, motion, and arrangement of divisible, impenetrable particles in a plenum are needed; occult qualities such as Aristotelian forms are unnecessary.

In *Entretiens de philosophie* (Paris, 1671), the companion volume to the *Traite*, Rohault explains in mechanical terms Cartesian opinions on animal machines and transubstantiation. Animal behavior, he claims, can be explained if animals are completely material; human behavior, however, requires a rational soul that is immaterial, hence indivisible, hence immortal. For Cartesians, the sensible qualities as they exist in material things are not seen, tasted, and so on as one sees and tastes them, but are merely the powers bodies have, determined by the size, figure, motion, and arrangement of their particles, to cause sensations in the mind. There is no further explanation of these powers beyond the fact that God made the correlations between bodily movements and one's sensory experience.

Transubstantiation, then, is the point-by-point replacement of bread and wine by Christ's flesh and blood. Therefore, the flesh and blood of Christ that occu-

pies the places (is bound by the surfaces) formerly occupied by bread and wine causes sensations exactly like those that the bread and wine formerly caused. Consequently, real accidents or Aristotelian forms subsisting separately from Aristotelian matter as postulated in the scholastic explanation of transubstantiation are unnecessary. There are further physical explanations and assurances that Cartesian principles do not contradict Catholic doctrine in *Oeuvres posthumes de Rohault* (Paris, 1682).

Overall, Rohault disclaims metaphysics and says that although the substitutions are miraculous, even his mechanist explanation of transubstantiation is only a solution to a problem in physics. His work illustrates the strong empiricist stress on observation and experiment toward probable mechanistic explanations in physics so prominent in many Cartesian philosophers. Finally, use of Rohault's *Traite* as a physics textbook merely with addition of Newtonian footnotes constitutes a major shift to nonmetaphysical, explanatory concerns in science.

ROMAGNOSI, GIAN DOMENICO (1761–1835)

Gian Domenico Romagnosi was born in Salsomaggiore, near Parma, and studied at the Collegio Alberoni in Piacenza. Through the teaching of Giovanni Antonio Comi, a follower of Gottfried Wilhelm Leibniz and Christian Wolff, Romagnosi became acquainted with the doctrines of Étienne Bonnot de Condillac and with the writings of Charles Bonnet, which had a decisive influence on him. After his graduation in 1786, he conceived his best-known work, *Genesi del diritto penale* (Genesis of Penal Law; completed in 1789 and published in Pavia in 1791), in which he claimed that the fundamental right to punish

belongs to society. Society alone, and not the individual, can mete out “that amount of evil that is necessary to preserve the well-being of our fellow men” and can oppose the “criminal impulse” with a “moral counterimpulse.”

Named mayor of Trent in 1791, Romagnosi remained in that office for ten years, during the period of the French Revolution and the rise of Napoleon Bonaparte. During this time he published, among other works, his *Cosa è l'eguaglianza* (What Is Equality?; Trent, 1792) and *Cosa è libertà* (What Is Freedom?; Trent, 1793). After a brilliant political career under the Napoleonic government, he became professor of natural and public law at Parma (1802), but after the restoration he was dismissed from his position and was arrested. The Austrian government also prevented him from accepting a post at the Ionian University at Corfu offered to him by Frederick North, Lord Guilford. Regarded as a master by Italian patriots, Romagnosi died, after a sad but active old age, in Milan. His major works, in addition to the *Genesi*, are considered to be the *Introduzione allo studio del diritto pubblico universale* (Introduction to the Study of Universal Public Law; Parma, 1805), the *Assunto primo della scienza del diritto naturale* (A First Thesis on the Science of Natural Law; Milan, 1820), and a series of essays on *incivilimento* (civilizing, or the process of civilization) in 1832.

Although he was influenced by the Enlightenment, Romagnosi remained attached to the historicism of Giambattista Vico and followed a “positive” method of research, advocating the activity of the human spirit rather than sensationalism and substituting for the abstractness of the isolated human individual the concreteness of the nation as the subject of the historical action. In epistemology he refused to reduce all cognitions to “transformed sensations,” but at the same time he denied that intelligence is independent of sensitivity: In reality, “discernment” is already present in “feeling.” The mind acts by means of its own “rational signs.” These cannot be regarded as preexisting ideas but, rather, as manifestations of mental activity, which, along with the sensory datum, gives form to experience. By contrast, the correspondence of our prior judgments with the actual signs of things, that is, with experience, constitutes the criterion of the truth of our knowledge, which is sought and found pragmatically.

Romagnosi's civil philosophy is the most interesting part of his work: Man is real only in a historically determined society—the “collective person of the society”—which is in a state of constant civilizing progress and whose characteristic traits, elements, and laws Romagnosi

sought to define. Romagnosi's doctrine of *incivilimento* constituted a philosophy of history faithful to the concrete development of real events, in contrast with that of G. W. F. Hegel, which Romagnosi opposed as "ultrameta-physical." Society develops through the synthesis of national character (tradition) with stimulation—spontaneous, free, and renewing—according to a law of convenience, with all parts of the nation tending toward an equilibrium of force and utility through the balance of interests and powers. This dialectic of civilization is a work of art, even the highest work of art of a humanity striving for perfection.

ROMAN PHILOSOPHY

See *Cicero, Marcus Tullius; Lucretius; Marcus Aurelius Antoninus; Seneca, Lucius Annaeus; Stoicism*

ROMANTICISM

"Romanticism" and "romantic" are protean words, the despair of a rigorous semanticist. They designate a gener-

ally accepted period, especially in literature and the arts, of Western cultural history, roughly from the late eighteenth to the mid-nineteenth century. They embrace a cluster or syndrome of ideas about the true, the good, the beautiful, philosophical ideas both in the popular and in the technical sense, ideas endlessly debated in the last few centuries. Although the behavioral scientists groping to establish a rigorous classification of human personality generally eschew the word, *romantic* remains in common use to describe a temperament or personality often, perhaps usually, held to be a constitutional element of an individual and at least in part independent of cultural fashion. In all these senses "romanticism" and "romantic" cover a multitude of particulars that in a given combination can appear very different, if not mutually incompatible. Hence so good a historian of ideas as Arthur Lovejoy urges the use of the plural, *romanticisms*, and can write of the "Chinese origins of a romanticism"; and W. T. Jones insists that romanticism can only be understood as a very complex syndrome of "biases" in the direction of what he calls the dynamic, the disordered, the continuous, the soft-focused, the inner, the this-worldly.

THE ROMANTIC TEMPERAMENT

Sensitive, emotional, preferring color to form, the exotic to the familiar, eager for novelty, for adventure, above all for the vicarious adventure of fantasy, reveling in disorder and uncertainty, insistent on the uniqueness of the individual to the point of making a virtue of eccentricity, the typical Romantic will hold that he cannot be typical, for the very concept of "typical" suggests the work of the pigeonholing intellect he scorns. Though his contempt for this world of reason and commonsense calculation may push him toward otherworldliness, the Romantic is too much a man of words and sensations to make a good mystic. He may admire the mystic, especially the exotic mystic from the East, but he himself is a good Westerner. In fact, the difficulties of reconciling the often contradictory particulars of romanticism in respectable generalization come out in any attempt to isolate a romantic personality. William Blake has most of the marks of the Romantic, from the positive one of extreme transcendental yearning to the almost universal romantic negative one of contempt for the "meddling intellect"; yet in his quite otherworldly drawings his symbolic, mystical figures are delineated with a draftsmanship of classical solidity and of firm this-worldliness. There is nothing fuzzy, nothing Turner-like, in Blake's art. William James has the full romantic love for the struggling, the unestablished, the untried; but he cannot be accused of what he

himself called “tender-mindedness,” of idealistic distrust of the instrument of thought. Friedrich Nietzsche, who used “romantic” as a term of reproach, who said of Richard Wagner’s music that it sweats, and called Mme. de Staël “that prolific ink-yielding cow,” shared all the romantic hatreds for the shopkeeper’s world of grubbing common sense and above all had the Romantic’s desire for *etwas mehr*, the something more of Percy Bysshe Shelley’s “desire of the moth for the star.”

However difficult the romantic personality may be to isolate in analysis, it can be recognized all through Western cultural history, and indeed in the active life of enterprise and politics. Euripides and Catullus were surely Romantics. The *Odi et amo* (I hate and I love) of Catullus is a classic assertion of romantic ambivalence; the *rumoresque senum severiorum/omnes unius aestimemus assis* (Let us regard all the gossip of censorious old men as not worth one penny) is a fine assertion of one of the minor marks of romanticism, contempt for the Philistine decencies of the old in spirit. François Villon and François Rabelais were Romantics, even though they were Frenchmen who, as Frenchmen, so nineteenth-century English and German romanticists thought, should have been incapable of transcending the petty ways of *mesure* and *la raison raisonnée*. In our own day, the romantic temperament crops up everywhere—in artists and poets of course, but also in philosophers. Henri Bergson was a Romantic. But so too, it may be argued, was A. N. Whitehead; and there are scientists not untouched by the desire of the moth for the star. In active life, Alexander the Great and Napoleon Bonaparte were Romantics; Frederick the Great and Otto von Bismarck were classicists.

There are then, in our Western civilization, presumably always born romanticists and born classicists—or born Dionysians and born Apollonians, to use an expressive dualism especially popular with the Germans from Gotthold Ephraim Lessing through Nietzsche to Oswald Spengler. (The Germans usually classify themselves as the great Dionysian force in the West.) We can but guess at the distribution of these two types in a general population. Probably the well-defined or extreme temperaments are limited in numbers always; most human beings can adapt to the fashion of their age. In one age, say Vergilian and Horatian Rome, or the France of Louis XIV, the Apollonian is dominant, the Dionysian subdued, even silent. Sometimes in Apollonian ages, however, the Dionysian is the rebel, the man out of tune with his times; Giambattista Vico, perhaps, should be so listed in the Apollonian early eighteenth century. In another age, and notably in the Romantic Age here considered, the

Dionysian is dominant and the Apollonian repressed, sometimes tempted, as was the quite unecstatic J. S. Mill, to romantic depths of understanding.

ROMANTICISM AND THE ENLIGHTENMENT

One type can be dominant, but not in sole and exclusive possession. To the cultural historian, the early and mid-eighteenth century and the early nineteenth can stand for two great antithetical styles or fashions: the first, classical or enlightened; the second, romantic. The years from about 1770 to the first decade of the nineteenth century are obviously years of transition. In a graph, the rising lines of Romanticism cross the descending lines of classicism somewhere in the 1770s in Germany (with the heyday of “Sturm und Drang”), 1798 in England (with the publication of the *Lyrical Ballads*), and 1820 in France (with the publication of *Méditations* by Alphonse-Marie-Louis de Prat de Lamartine). But even after the triumph of Romanticism as a cultural fashion, individuals and groups continued to display the tastes and attitudes associated with the classicism and rationalism of the eighteenth-century Enlightenment. J. S. Mill tells us in his autobiography that he was influenced by the lyricism and even the transcendentalism of the Lake poets, notably Samuel Taylor Coleridge; but the influence seems not to have weaned him away from the fundamentals of Benthamite thought. In France the thought of such men as Comte de Saint-Simon, Louis Blanc, Auguste Comte, though some of the externals of romantic fashion are visible among them, is, on the whole, along with that of the French Left generally, true to the traditions of the *philosophes*. Even in Germany, a philosopher such as Ludwig Feuerbach asserts the unromantic doctrines of materialism; and Marxism itself, though it shows romantic marks—the concept of the dialectic, derived of course from G. W. F. Hegel, is essentially romantic in its insistence on change as an overcoming of contradictions—is nonetheless committed to an optimistic and very eighteenth-century stand on the rational organization of man and society.

The romantic generation was indeed very conscious of breaking sharply with its parents and grandparents. Few breaks between cultural generations in the West have been more vigorously asserted than this one. The romantic youth absorbed in the depths of William Wordsworth’s *Prelude*, or Vicomte Chateaubriand’s *Génie du Christianisme*, or Johann Wolfgang von Goethe’s *Faust* felt nothing but contempt for the abstract ideas and the confined tastes of his shallow Voltairian grandfather. To a

surprising extent, the fashionable Romantic was—or claimed to be—in all things the opposite of the Enlightened. Yet our own generation can hardly avoid holding that the romantic rebellion against its parent was in itself a proof of the filial relation between Romanticism and Enlightenment. Not only were the ideas of men like Jean-Jacques Rousseau, Vico, Lessing, and even Denis Diderot, all of whom lived at the height of the Enlightenment, seminal to all later Romanticism, but both Enlightenment and Romanticism shared much—a belief in process, change, if not actually progress, a belief in the possibilities of manipulating the environment, indeed a fundamental and very modern relativism never really transcended in the search for eternal verities. Both, whatever their metaphysical position on the problem of determinism, in practice displayed a firm conviction that things not only change, but that they can be changed by human effort. Of many specific doctrines—primitivism, for instance, or individualism in ethics and politics—it is hard to decide whether they are more characteristic of enlightened or of romantic thought.

SOME SPECIFIC ROMANTICISMS: ART AND LETTERS

The romantic touch is extremely visible in all the arts, from painting through architecture to interior decoration. Bright colors, or soft and fuzzy ones; exotic themes, Oriental scenes; crowded and action-filled historical paintings—concretely, almost any canvas by Eugène Delacroix—set romantic painting off from the sculptured Roman figures of David. And yet, to point up the coexistence of the romantic and the classical throughout the period, the sharp outlines, the measured realism—the Romantic would hold, the conventionality—of the portraits by Jean-Auguste-Dominique Ingres, who survived until 1867, outdo David's in classical firmness. The great romantic style in architecture was the neo-Gothic, itself a manifestation of the romantic rehabilitation of everything medieval that had been held in contempt by the Renaissance and Enlightenment. Yet Neo-Gothic was never a dominant style, not even in the Nordic lands; moreover, it soon fell into a most unmedieval and unromantic regularity and repetitiveness of detail. But Romanticism did rescue from the neglect in which they had long been left the great medieval cathedrals. In the decorative arts romantic tastes were extremely eclectic, fond of the exotic, addicted to rich dark woods and, in the climax of the Victorian drawing room, to a clutter of display wholly dependent on the existence of inexpensive domestic labor. In music, the romantic at its extreme

went in for program music, birdcalls and thunderstorms, vast orchestras, and appropriate dissonances. The difference between the music of Joseph Haydn or Wolfgang Amadeus Mozart and that of Hector Berlioz or Wagner, like that between the painting of David and that of Delacroix, is obvious to the most untutored.

Poetry, the novel, and history are the great romantic literary genres, and in all of them the romantic syndrome is readily recognized. Although Goethe was a complex personality who was frequently in conflict with contemporary representatives of the romantic movement, his *Faust* is in itself a masterly summary of romantic themes: revolt against the dullness, the narrowness of rationalism (“gray dear friend is all theory, green only life's eternal tree”), striving for *etwas mehr*, for the infinite (the essential theme of Faust's bargain with Mephistopheles); contempt for the Philistine, the literal-minded ordinary man (the walk with Wagner); primitivism (Gretchen's innocence); ambivalence (“Two souls, alas, live in my breast”); and much else, right on to the final *chorus mysticus* of Part II. Indeed, this last is a fine touchstone; anyone who finds it nonsense or at least unpalatable is definitely not Romantic:

Alles Vergängliche
Ist nur ein Gleichnis;
Das Unzulängliche
Hier wird's Ereignis;
Das Unbeschreibliche
Hier ist's getan;
Das Ewig-Weibliche
Zieht uns hinan.

The three English Lake Poets, Wordsworth, Coleridge, and Robert Southey, together pretty well cover the romantic range; and Wordsworth's “The Tables Turned” (“One impulse from a vernal wood,” “We murder to dissect,” “Enough of science and of art;/Close up those barren leaves”) states the central position of the romantic *Weltanschauung* almost as neatly as Goethe's *Gefühl ist alles*. One more figure, one more complex of themes, is needed to round out our concept of romantic poetry: This is the unhappy, misunderstood, heroic Promethean figure, half Shelley and all Lord Byron. In terms of sheer educated fashion, Byron and his whole train of European congeners (imitators would be an unfair word here)—Alfred de Musset, Alfred-Victor de Vigny, Giacomo Leopardi, José de Espronceda, Mikhail Lermontov, and the rest—may stand for the romantic poet.

Forerunners of the romantic novel are clear in the eighteenth-century “Gothic” novel, such as those of Ann Radcliffe (so charmingly satirized by the nonromantic

Jane Austen in *Northanger Abbey*); in the sentimental novel, such as Rousseau's *Nouvelle Héloïse*; and in the psychological novel of disturbed and disturbing love, such as Pierre-Ambroise-François Choderlos de Laclos's *Liaisons dangereuses* and the novels of the Marquis de Sade. The psychological novel reaches its best in the work of Stendhal, whose heroes foreshadow a long line of adventurers of soul and body, a line by no means extinct today. Yet in terms of the wider public of romantic fashion, Walter Scott's Waverley novels were the great success of their day. They carried their audience back into a simpler, more varied, more interesting past than the present of the Industrial Revolution. They exemplified that other inheritance from the German side of the Enlightenment, the theme, best marked in Johann Gottfried Herder, of organic historic growth of a folk spirit, a folk character, a product of time, not a product of the planning, present-bound intellect. One lost one's self in Sir Walter's pages, became one with one's own best past. We are a long way from Henry St. John Bolingbroke's definition of history as "philosophy teaching by examples."

HISTORY AND POLITICAL THOUGHT

The writing of serious history received a great impetus from the romantic movement, and in particular from Scott's work. Augustin Thierry, Jules Michelet, the Heidelberg school in Germany; in England Henry Hallam, indeed T. Macaulay, by no means a Romantic in temperament; and in the United States the great New England school of W. H. Prescott, J. L. Motley, and Francis Parkman wrote history for a wide reading public, history with narrative force and movement, history with a message of patriotism, of identification with a folk, yet also history carefully reconstructed by painstaking research. The historian and the critic of art and literature insisted on one of the great romantic themes: continuity, the continuity of life and flow, growth, development; a process, to the Romantic, always denatured, indeed destroyed, by the dividing analytical mind ("We murder to dissect").

The complexities and difficulties of generalizing about Romanticism come out most clearly, perhaps, in the field of political thought. You can, of course, always construct a pair of Procrustean beds: a conservative bed for the Romantics; a liberal, progressive, or radical bed for the Enlightened. Edmund Burke and Scott can be squeezed into the first, Thomas Paine, W. Godwin, Thomas Jefferson into the second. But the trouble is that you can quite plausibly switch the beds, putting the Romantics into the liberal or progressive bed, the Enlightened into the conservative bed. Shelley, Byron,

Benjamin Constant can go into the first; Voltaire (surely no democrat), John Adams, the *idéologues* who rallied to Napoleon can go into the second. But Victor Hugo would have to be divided, his younger self put into the conservative, his older self into the liberal bed.

Critics have indeed tried to fix Romanticism on one side or the other in politics, and—given their premises—not without some success. Probably in the balance Romanticism has worked toward the growth of modern democracy, toward a belief in progress and toward "liberty, equality, fraternity," toward the open society—toward much, in fact, that gets its start from the rationalists of the Enlightenment. Yet the Burkean belief in human fallibility, human blindness of passion, and in tradition-enshrined institutional dikes to restrain these anarchic thrusts (dikes not to be tampered with by the intellect), as well as belief in the folk, in an organic society not the product of planning, is surely also congruous with much of Romanticism. So too is the anti-intellectual strain that comes out much later in theories of racism, elitism, *Blut und Boden*, in Nazism and Fascism.

PHILOSOPHY

Romanticism is more than a fashion in arts and letters, more than an approach to political problems: It is a philosophy, or better, a set of philosophies loosely tied together if only by their common rejection of eighteenth-century rationalism, of refusal to line up, shall we say, on the Locke-Hume axis. Arthur Schopenhauer is the arch Romantic, the extreme Romantic, among formal philosophers. The world of phenomena, of sense perception, is to him unreal; the will that moves the universe is real enough, but certainly is not rationally knowable by those it moves; this will is blind, shapeless, evil; life, merely phenomenal though it is, is still for us all painful, wearisome, a long unhappy voyage (note the metaphors of movement); Schopenhauer seems at times to hold that a nirvana of surcease is perhaps attainable; at any rate, this life is hopeless.

Romantic pessimism is not, however, the central theme of philosophy in these years. Hegel, at bottom an optimist, is much more central. In a sense, the great romantic philosophers, most of them Germans, go back to Immanuel Kant, who always thought of himself as firmly enlightened, and whose brief *Was ist Aufklärung?* is one of the landmarks of the century of prose and reason. The romantic seedling in Kant, however, is his distinction between the noumenal and the phenomenal, and his resolution of the dualism by what amounts to intuition or faith. Johann Gottlieb Fichte and Friedrich Schleierma-

cher and the rest developed this essentially romantic reliance on a “faculty” transcending common calculating logic. Hegel accepted, and gave his own turn to, this very old dualism of spirit-matter, real-unreal, and sought to bring them together by his famous and influential concept of the dialectic of thesis–antithesis–synthesis. The dialectic in all its forms displays a most nineteenth-century and romantic general bias toward historicism, process, development—but such a process seen teleologically as an end, a purpose. For Schopenhauer, there was no end save extinction. But for Hegel there was an end, a vague one, a Germanic eternal peace in which change somehow turns out to be, in the workings of the World-Spirit, the real form of permanence.

These philosophers, trained and subtle professionals whom we have no doubt traduced in this brief account, are less definitely to be associated with Romanticism as a broad cultural movement than the popularizers, the essayists, the preachers. To many devotees of Thomas Carlyle, Ralph Waldo Emerson, and John Ruskin, and to those who listened to bumblerers like Bronson Alcott, romantic philosophy became fashionable transcendentalism, an agreeable summary of the less difficult phases of romantic thought—contempt for the rationalist side of the eighteenth century (indeed, blindness to the existence of any other side of that century), exaltation of intuition, spirit, sensibility, imagination, faith, the unmeasurable, the infinite, the wordless—or at least, only the noblest sounding words. This sort of Romanticism was indeed a solace and an escape, an escape from the difficult and unlovely works that science, technology, and industry were building. But it is by no means the whole of Romanticism, which as a spiritual spur to precisely the kind of invention, adventure, and enterprise, to the preoccupation with change and growth, that was building the new world of the nineteenth century, must be seen as having played, and as continuing to play, an essential part, along with the rational and scientific inheritance from the eighteenth-century Enlightenment, in building our own world of today.

Bibliography

Romanticism is not only a complex cluster of ideas; it is one that arouses strong feelings among critics and historians, and that has had its ups and downs in the estimation of the various cultural generations since the late eighteenth century. The following should set the reader on his way through these thickets of critical and philosophical discussion of Romanticism.

Howard Hugo, ed., *The Romantic Reader* (New York: Viking Press, 1957), is an admirable anthology with a good bibliography of works in English and a useful prologue, “What the Romantics Said about Romanticism.” W. T. Jones, *The Romantic Syndrome* (The Hague: Nijhoff, 1961), presents a very suggestive analysis, helpful for all study of the history of ideas. Jacques Barzun, *Classic, Romantic and Modern* (Boston: Little, Brown, 1961), contains the ablest defense of Romanticism; see the section “Romantic—A Sampling of Modern Usage” (pp. 155–168). G. A. Borgese, “Romanticism,” *Encyclopaedia of the Social Sciences* (New York, 1934), Vol. XIII (VII), a remarkably rich brief account, with full bibliographies up to 1934 in all Western tongues, is sympathetic. Irving Babbitt, *Rousseau and Romanticism* (Boston: Houghton Mifflin, 1919), is still the sharpest attack on Romanticism. A. O. Lovejoy, *Essays in the History of Ideas* (Baltimore: Johns Hopkins University Press, 1948), contains several pertinent essays, especially one titled “On the Discrimination of Romanticisms.” Sir Maurice Bowra, *The Romantic Imagination* (Cambridge, MA: Harvard University Press, 1949), is a graceful essay by a distinguished English scholar and critic. Walter Jackson Bate, *From Classic to Romantic* (Cambridge, MA: Harvard University Press, 1946), is one of the best studies of the complex interweaving of classic and romantic in English literature. Ricarda Huch, *Blütezeit der Romantik*, 12th ed. (Leipzig, 1922), and *Ausbreitung und Verfall der Romantik*, 10th ed. (Leipzig, 1922), are sympathetic and graceful accounts of the German Romantics. Pierre Lasserre, *Le Romantisme français* (Paris, 1907), is an unsympathetic account of the French Romantics.

Crane Brinton (1967)

ROMANTICISM [ADDENDUM]

When romanticism is understood broadly, as referring to a major development in European thought and culture

since the turn of the nineteenth century that shows itself distinctly in the spheres of art, historical writing, and political thought, the concept has only a limited role to play in the history of philosophy: Certain very general notions—an emphasis on agency, expression, the cognitive dimension of affect, and the potential of human beings to become genuine wholes—can be described as manifestations of romanticism in philosophy, but the term does not serve to pick out any more determinate set of philosophical commitments.

Here, as with modernism, is a category that is indispensable for general intellectual history, but lacks equivalent value in the history of philosophy. Where the concept does achieve significant purpose in the history of philosophy is in its much narrower application to the group of thinkers based in Jena at the very end of the eighteenth century known as the (early) German romantics, or *Frühromantik*, whose activity centered on production of the *Athenäum*, a journal whose historical importance far exceeds its short life span. Friedrich von Schlegel and Novalis (the pen name of Friedrich von Hardenberg) comprise the philosophical core of German romanticism, with F. W. J. von Schelling and F. D. E. Schleiermacher in close, albeit temporary and qualified, association. J. C. F. Hölderlin—like Novalis, a major German lyric poet—did not belong to the group in Jena but is considered properly as belonging to the same philosophical tendency as Schlegel and Novalis.

Philosophical understanding of the German romantics has been obstructed by the fragmentary form of much of their output, and the literary concern of the movement taken as a ground for assuming its importance to lie outside philosophy, but more recent work, above all by Manfred Frank (b. 1945), Ernst Behler (b. 1928), and Frederick Beiser (b. 1949), has revealed the distinctiveness and importance of the philosophical outlook formulated by the German romantics in the context of the problems and issues facing post-Kantian philosophy. The problems of Immanuel Kant's legacy revolved in the first place around the perceived incompleteness of Kant's transcendental or critical philosophy, which was considered to have opened up a new range of intellectual possibilities and yet to require further development for it to fulfil its emancipatory promise and thereby meet the demands of the age. Johann Gottlieb Fichte's attempt to do exactly this in his *Wissenschaftslehre* held the attention of, but failed to convince, the German romantics, who accepted the rational necessity of seeking to construct a self-grounding philosophical system but believed themselves

to have achieved insight into the reasons why this ideal cannot be realized and must remain an infinite task.

Schlegel's original and influential conception of irony as not merely a literary trope, but rather a corollary of the structure of reflection that, having achieved critical freedom, cannot bring itself to a halt, was developed in part to rationalize this complex attitude toward the ideal of philosophical systematicity. The reorientation proposed by the German romantics in place of Fichte's *Wissenschaftslehre* centered on a novel and very high valorization of art and the aesthetic. This move, far from signalling an aestheticist turning away from the philosophical tasks and the social and political realities that occupied Kant and Fichte, was envisaged as engaging with the full spectrum of philosophical, practical, and cultural problems. The key to the importance ascribed by the German romantics to art—at least, to that art which possesses the qualities of what they called *Poesie* (*romantische*)—lay in its supreme exemplification of true (organic) unity, its synthetic relation to the metaphysical oppositions that structure human existence and reality at large, and its embodiment or symbolization of freedom.

Both this conception of art and the romantics' claim for its practical importance show the influence of Schiller's *Letters on Aesthetic Education*, but the German romantics projected the concept of art and the aesthetic, in a way that Schiller had not, well beyond the sphere of works of art in the strict sense. Schelling's account in the final part of his *System of Transcendental Idealism* of art as what he calls the only true organ and document of philosophy provided one formulation of the German romantic idea that art is philosophically preeminent, and the *Naturphilosophie* that Schelling developed in the late 1790s, which attributes organic status to nature as a whole, and disputes the primacy of mechanism over teleology maintained in modern philosophy even by Kant, falls equally into line with the German romantic program.

In the ethical and political sphere, the German romantics sought to achieve recognition for the claims of personal individuality while at the same time urging the pursuit of organic wholeness in collective life, in opposition to Kant's ethical universalism and political atomism, yet without any intention of contradicting Kant's modern affirmation of freedom. Schleiermacher's ethical theory, though it was composed some years after the dissolution of the romantic circle, may be regarded as giving systematic shape to at least some German romantic ethical insights, in the same way that his earlier, highly successful

work, *On Religion*, stood in close accord with the German romantic intention to recreate religious forms.

German romanticism has affinities with positions that had been developed earlier by J. G. Hamann, J. G. Herder, and F. H. Jacobi in their critique of the German Enlightenment, and some commentators have suggested that it also prefigures deconstruction and postmodern philosophy, on account of its skepticism regarding the attainability of final philosophical truth. This view runs a risk of anachronism, however, for while it is true that German romanticism diverges from the three great developments of German idealism, it nevertheless remains committed to an ideal of rationality and retains many of the idealistic, not to say Platonistic, elements that are present in the philosophies of Fichte, Schelling, and Hegel. Indicative in this regard is the fact that the sharp criticism made by Hegel of German romanticism—which collapses, Hegel believes, into hyper-subjectivism and arbitrariness—is premised on an understanding of the movement as having grasped, without giving adequate form to, important philosophical truths.

ROMERO, FRANCISCO (1891–1962)

Francisco Romero, the Argentine philosopher of transcendence, was born in Seville, Spain, but moved to Argentina as a child. After military and literary careers he turned to philosophy, joining the faculty of the University of Buenos Aires in 1928 and of La Plata in 1929. He renounced his academic posts in 1946 in protest against the government of Juan Perón but resumed them in 1955. Because of his conceptual discipline, scope, originality of thought, and limpid clarity of style, Romero is considered one of the ablest and most satisfying of Latin American philosophers.

The idea of transcendence dominates and unifies Romero's metaphysics and theories of knowledge and

values. Transcendence implies at least the diversity achieved by passing beyond a given condition or limit and suggests a universal impetus or agency of such passage, an agency that may be purposive. Opposed to transcendence is immanence, which implies identity and containment within, or return to, a limit. Of the two major forms of transcendence, one is that relation of parts to each other in a structural whole by which novel characteristics emerge that were only latent in the parts considered separately. The other form of transcendence is change and, in particular, evolution in the creative and vitalistic sense of Henri Bergson. Its immanent reduction occurs in the mechanistic evolutionary views of Charles Darwin and Herbert Spencer.

Romero identified reason with immanence; experience, in a broad sense, is related to transcendence. Reason may be either intuitive or discursive. In either case it demands identity and transparency. Identity is found in homogeneity and in permanence; it leads reason to the mechanistic conception of atoms that are similar in kind, endure in time, and are governed by causal laws that presuppose the identification of effects with their causes. Transparency, or clarity, is found in forms emptied of content and in the space in which atoms move and with which they tend to be identified.

Reason is formal only and has no avenue of its own to reality and concrete fact. It is not identical with intelligence, which may criticize it. Where reason fails, experience succeeds. Experience supplies a datum by which knowing must be guided. The objects of experience are not sense data and perceptual objects alone, but also essences and values. In addition, Romero held open the possibility of a metaphysical experience of something ultimate and noumenal but subject to connection with ordinary experience and its phenomenal objects.

Romero divided phenomena into four strata, of which each level is a ground for the next and has greater scope for transcendence than the preceding level. The physical level, that of space and moving atoms, is most pervaded with immanence, but the shift in physical theory from the rigid corpuscle to the *foco activísimo* means a greater emphasis on the role of transcendence even on this level. The vital level is characterized by true duration, a factor of transcendence. The psychical level involves consciousness, which intends, or transcends toward, an object, but there is a countering immanence in the egocentric tendency of the human individual to absorb the object into his own forms and needs. On the spiritual level, the human person, rising above his egocentric needs and attaining a universal subjectivity, contemplates the

object disinterestedly in the sphere of knowing and conducts himself altruistically and with regard to general principles in the sphere of action. On the spiritual level transcendence becomes absolute. The person is transcendence incarnate and unqualified. Each level contains and is supported by transcendence, but each is unique and irreducible.

Romero, proceeding cautiously and with an air of hypothesis, proposed that Arthur Schopenhauer and Bergson were not wrong in positing a metaphysical datum, but that they misconstrued it. Schopenhauer's will and Bergson's vital impulse are forms of transcendence, which is a more general and basic being than either. Romero did not try to sketch the nature of this being, but he appears to have thought of it as a universal impulse at work in every level of phenomenal transcendence, an impetus that is the essence of reality, the source of value, and possibly the spirit's point of flower, which this being intended from the beginning.

RORETZ, KARL

(1881–1967)

Karl Roretz, the Austrian epistemologist, philosopher of culture, and aesthetician, was born at Schloss Breitenreich. He studied law, and later philosophy, at the University of Vienna, receiving his doctorate in 1906 with the dissertation "The Problem of Empathy in Modern Aesthetics." In 1922 Roretz became a *Privatdozent* at the university and taught history of modern philosophy until 1938, when he ceased lecturing after the Nazi takeover of Austria. He resumed lecturing in 1945 and continued until his retire-

ment in 1951.

As an epistemologist, Roretz espoused a “critical positivism,” a philosophy whose foundation is both scientific and, in Immanuel Kant’s sense, criticist. The outstanding features of his thought are critical reflection, skeptical rationality, intellectual honesty, and independence of mind. He rejected dogmatism and unsupported metaphysical speculation. Like Hans Vaihinger, he regarded metaphysical concepts as self-contradictory fictions. Thus, Roretz held, metaphysics lacks any purely logical meaning.

Roretz’s major work, *An den Quellen unseres Denkens* (Vienna, 1937), contains his most acute epistemological analyses. In this monograph he studied “vital concepts,” concepts in whose formation an element of will or an element of value plays a decisive part and whose definition is therefore preceded by a decision. Among such concepts are those of art, of ethics, of popular education, and of the slave trade.

Roretz’s elegant and penetrating psychological analyses of culture and his critical analyses of values deserve particular consideration. The decline of spiritual values, he contended, is due to internal degeneration or disintegration within the person and the society, and only seldom to external pressure. He also studied the genesis and structure of mass psychological phenomena (“mass, illnesses,” *Massenerkrankungen*) in religion, politics, economics, art, fashion, and sports—notably such extremely dangerous religious and other spiritual “epidemics” as belief in vampires and devils, witch-hunting, and racial persecution.

As a philosopher of culture, Roretz felt most akin to Friedrich Nietzsche. Like Nietzsche, he believed in life with a deep conviction. But Roretz’s view of life was Kantian, and the meaning of life for him consisted in working at the problems life poses. He advocated a philosophy that interpreted reality from an aesthetic point of view. Such a philosophy, he held, provides an orientation toward life and the world that is biologically optimal. The world appears, in this view, as a drama without metaphysical supramundane or transmundane galleries to which it must play. Roretz professed a deep joy in the variegated splendor of the world. “The meaning of the world,” he wrote, “is an aesthetic meaning.”

In his studies of what he called intellectual-aesthetic values—aesthetic effects bound up with specific achievements of thought, as in mathematics, strategy, or chess—Roretz made important contributions to aesthetics itself.

His interest in ethical problems was equally great. A convinced humanist and democrat, he supported the Ethical Culture movement and strove for a secular ethics independent of any metaphysical or religious assumptions.

RORTY, RICHARD

(1931–)

An American philosopher and pragmatist, Rorty is among the most widely discussed and controversial philosophers at the turn of the twenty-first century. A New Yorker by birth, Richard Rorty was educated at the University of Chicago (1946–1952) and at Yale (1952–1956) where he received his doctorate in philosophy. After brief flirtations with Platonism and the work of A. N. Whitehead, Rorty’s more mature interests began to form at the end of his military service in 1958, at which point he began serious study of the philosophers who would later number among his chief influences: Wilfrid Sellars, Ludwig Wittgenstein, Martin Heidegger, John Dewey, and W.V. O. Quine.

EARLY PERIOD

Rorty’s early work in analytic philosophy, sometimes thought to represent a completely distinct period, is in fact touched by two themes that resurface throughout his career. The first theme is anti-Cartesianism about the mind and knowledge. In a series of papers written during the 1960s Rorty was the first to develop a subsequently contentious theory in the philosophy of mind—eliminative materialism, which holds that the mind and mental

states are theoretical, and hence dispensable, constructions.

The second theme is an abiding concern with the function and importance of philosophy. Again, this theme appears early on, particularly in Rorty's 1967 introduction to *The Linguistic Turn*, a collection of essays on analytic philosophy of language. In his introduction, Rorty praised analytic philosophy for knocking the entire philosophical tradition on its heels—a sentiment that he would later characterize as naïve. In subsequent work, Rorty came to believe that mainstream Anglo-American philosophy of language makes many of the same mistakes as the intellectual traditions he had earlier taken it to supplant.

ANTIREPRESENTATIONALISM

This latter sentiment first emerges in Rorty's seminal book, *Philosophy and The Mirror of Nature* (hereafter: PMN). Originally published in 1979, and at once hailed and denounced as a critique of analytic philosophy, the book brings together Rorty's hostility to Cartesianism with a positive vision about the nature and limits of philosophy.

At its core, PMN is a sustained attack on representationalism. According to representationalism—which Rorty argues is a largely unquestioned assumption of Cartesian and Kantian philosophy—the mind is a device for representing the world and knowledge is accurate representation. Rorty holds the representationalism responsible for two major philosophical mistakes: a false dualism of mind and body, and a bankrupt foundationalist picture of knowledge, which holds that all knowledge must sit on the foundation stones of intrinsically accurate privileged representations. Moreover, Rorty takes representationalism to paint a misleading picture of philosophy's importance—as a master discipline that judges whether the claims of science, morality, or art can represent reality.

In Rorty's view, twentieth-century linguistic philosophy continued to assume representationalism (and its mistakes) in a linguistic guise—an opinion he sees as shared by philosophers as diverse as Dewey, Quine, Sellars, Wittgenstein, and Donald Davidson. Following Quine and Wittgenstein, for example, he argues that the notions of meaning and analyticity are mere linguistic shadows of the privileged mental representations of the early moderns. And with Sellars, he rejects “the given,” or theoretically innocent sense-experience, as a myth. His moral: language, like the mind, should not be understood as a device for representing a ready-made world.

In opposition to representationalism, Rorty suggested in PMN that we should adopt what he called *epistemological behaviorism*, and explain epistemic rationality and justification in terms of what our society will let us say, rather than the other way around. The thought is that there is no mystery about how the mind represents the world. The very idea of such representation is a fable; what claims we accept as knowledge depends not on how well they mirror the world but on how well they hang together with what else we already accept. Accordingly, Rorty concluded, philosophy has nothing distinctive to offer about knowledge. To learn why we accept what we accept we must turn to biology, psychology, and sociology; Charles Darwin will have more to teach us about the mind than René Descartes. The philosopher's role was instead therapeutic—to cure of us intellectual maladies—and revisionary so as to convince us to engage in new forms of conversations.

PRAGMATISM AND TRUTH

Rorty has continually emphasized that his view is a form of pragmatism—particularly the pragmatism of Dewey. And much like the classical pragmatists before him, he sees his debate with the representationalist as coming down to a debate over how to understand truth.

Yet Rorty's own views on truth shifted in subtle ways over the course of his career. He always rejected the correspondence theory of truth, according to which a statement is true just when it corresponds to the facts. But in his earlier work, Rorty was tempted to follow the classical pragmatists and define truth in terms of justification or warranted assertibility. Truth, on his version of the view, simply is what we are justified in believing in light of our cultural practices. But in later works, Rorty has come to see this position as another misguided attempt to uncover the secret nature of truth. The contemporary pragmatist, Rorty argues, should instead simply reject the idea that truth has any nature at all. Truth is not the sort of thing that can be defined—not because its nature is mysterious or ineffable, but because there is nothing general and informative one can say about what is in common between “Snow is white,” “Two and two are four” and “Democracy is a better form of government than tyranny.” There simply is no metaphysically substantive property of truth that some propositions have and others lack.

Rorty argues that adopting this attitude toward truth has several important consequences. In his later work, for example, he has particularly emphasized that, for the pragmatist, truth is not a goal of inquiry. According to

Rorty, something can only be a goal if we can recognize when we have reached it. But whenever we check to see whether our beliefs are true, we can only discover whether they are justified or unjustified. Thus we should give up on the idea that we are aiming at truth; instead, Rorty says, echoing Davidson, we should see ourselves as aiming only at honest justification. And for Rorty, justification is a practical matter—what beliefs we find justified depends on whether we can use them in achieving the aims of our culture. Nonetheless, truth is not reducible to what our immediate community finds useful because one important function of the word *true* in our language is to remind us that what may be practically justified to some audiences may not be justified to all.

Rorty's views on truth have drawn considerable criticism. He is often derided as advocating a naïve form of cultural relativism. But Rorty insists that it is as misleading to describe him as a relativist as it would be to describe him as a realist. In Rorty's eyes, the realist and the relativist commit linked sins: the realist by taking the world to be ready-made, the relativist by thinking it is made by us. From the Rortyan perspective, we should instead take truth making—whether understood in a realist or relativist fashion—as simply a metaphor that should be given up. Consequently, Rorty might be better described as advocating a form of quietism about metaphysics and epistemology.

DEMOCRACY AND PHILOSOPHY

Rorty takes the failure of representationalism as linked with the failure of another enlightenment project: the project of grounding our political ideals in a common human nature. For Rorty, democratic, liberal government is a great achievement, but it is not an achievement whose value can be given a philosophical justification. Rather than trying to justify liberal democratic ideals philosophically, we should instead seek to ground our philosophical ideals in our democratic values. Thus we should stop searching for objective foundations and instead aim for solidarity with our fellows.

Rorty describes his positive political position as *liberal irony*. It is liberal because it takes self-creation and freedom as central values. Individuals should be free from suffering and cruelty, but also free to create and live their own vision of the good life. But the Rortyan liberal also takes an ironic stance toward his own liberal commitments. He realizes that his values are contingent reflections of his own time and place, and not reflections of the values of the world itself. To those critics who protest that this position is too weak to offer sufficient defense against

the tyrant, Rorty responds that philosophy is of no use against tyranny anyway, and that those who believe that all is lost without appeal to the world's own true values are much like those nineteenth-century intellectuals who believed that without God, everything was permitted.

Rorty has sometimes been charged with no longer doing philosophy. And that charge is fair if one takes philosophy to be in the job of representing the world as it is in itself. But Rorty's own views encourage a different view of philosophy, according to which the job of the philosophy is not so much to discover the world's own language as he sometimes put it, but to invent new vocabularies and means of description. In this sense, Rorty's stance toward philosophy is Marxian: The goal of the philosopher is not to map the landscape as it is, but change how we see the world; to paint new landscapes, new pictures.

ROSCELIN (1050–1120)

Despite much scholarly effort, little is known about Roscelin of Compiègne. The only work that we can safely attribute to him is a letter he sent to Peter Abelard around 1119–1120. In this ill-tempered piece of writing Roscelin sets out to distinguish his position on the Trinity from

that which Abelard was developing in his *Theologia Summi Boni*.

The problem for Roscelin and Abelard is to give an account of the distinction between the persons of the Trinity compatible with the unity of God. Roscelin notes that he has to navigate here between two heresies: Sabellianism, requiring such a unity in the singular substance of God that the distinction between the persons can be only verbal, and Arianism, which distinguishes the persons as greater and lesser so as to constitute three distinct gods. Roscelin, in effect, accused his former student of Sabellianism, and so contributed to Abelard's being called before the Council of Soissons in 1121 and required to burn a copy of his *Theologia Summi Boni* and confirm his orthodoxy.

Roscelin's position is that the names *Father*, *Son*, and *Holy Spirit* pick out distinct items but that these exist in God with the unity of likeness and equality. Unfortunately he invokes authority rather than arguing for his theory. It has recently been suggested by author Constant Mews, however, that Roscelin depends on an account of the semantics of names developed in contemporary writing on grammar.

Our remaining information about Roscelin comes from two unsympathetic reporters. Abelard, in a letter written around 1119, complains about Roscelin's attack on him and recalls that long before, at the Council of Soissons in 1092, Roscelin had been charged with tritheism. From Saint Anselm we have two letters from 1090–1092, and the treatise *De incarnatione verbi*, written after the Council, in which Roscelin is said to have maintained that the persons of the Trinity are as separate from one another as three angels, or three souls. This is certainly not what he claims in his letter to Abelard, which may thus represent a refinement of his theory in response to Anselm's objections. In *De incarnatione verbi* Anselm characterizes Roscelin as a heretic in logic who holds that universal substances are nothing more than "puffs of air made with the voice," who cannot distinguish a body from its color, or a soul from its wisdom, and cannot understand how human beings are one in species.

In the middle of the twelfth century Roscelin was said to have been the first to have upheld the doctrine of words (*sententia vocum*). From the information given, however, it is impossible to recover anything of his theory. We are told by John of Salisbury that he held that utterances themselves were genera and species. This is the position advocated in the *Dialectica* of Garlandus Compotista, written around 1115, which may provide our best

guide to the views of Roscelin and those referred to at the time as the *Vocales*.

Appealing to Garlandus, Abelard's early writings, and various other texts, author John Marenbon has argued that vocalism in general and perhaps Roscelin's views in particular, developed out of what he calls the *in voce* reading of Porphyry's *Isagoge* and Aristotle's *Categories*. In this exegetical procedure, he suggests, theoretical commitment was suppressed in favor of reading the texts as simply about the relations between words.

Abelard confirms in his letter that Roscelin held that universals are in some sense words, and parodies him by saying he would have to read Scripture as claiming that Christ ate the expression *broiled fish* rather than the fish itself. It is unfortunately impossible to tell whether Abelard is constructing or reporting an argument when he reports, in his *Dialectica*, that as well as holding that species are words, Roscelin claimed that things do not have parts—so a wall is not part of a house. Perhaps what was really at issue were the questions that seem to have exercised Roscelin throughout his career: What counts as a thing and what is the nature of unity?

ROSENKRANZ, JOHANN KARL FRIEDRICH (1805–1879)

Johann Karl Friedrich Rosenkranz, the German Hegelian philosopher, was born in Magdeburg. He entered the University of Berlin in 1824. Although he was to become G. W. F. Hegel's most devoted disciple, Rosenkranz was first drawn to Friedrich Schleiermacher; he heard only an occasional lecture by Hegel and was unimpressed. He began reading Hegel as a student at Halle in 1826 and the following year came under the influence of Karl Daub (1765–1836), a Hegelian theologian at Heidelberg. As a *Privatdozent* and extraordinary professor at Halle,

Rosenkranz participated actively in the Hegelian circle there. Called to Berlin, he struck up a friendship with Hegel and joined his birthday celebration a few weeks before Hegel died of cholera in 1831. Rosenkranz himself was stricken almost fatally with the disease, reflecting, as he later reported, that this was carrying discipleship entirely too far. In 1833 he succeeded Johann Friedrich Herbart as professor of philosophy at the University of Königsberg, where he remained until his death except for a brief political career in Berlin during the revolutionary crisis of 1848/1849.

Rosenkranz wrote over forty substantial works, on systematic philosophy, aesthetics, theology, logic, psychology, literary history, pedagogics, philosophical history and biography, and political and social theory. He also composed poetry and contributed articles on current issues to the newspapers.

Rosenkranz defended the Hegelian system as the authentic expression of the German spirit and the fulfillment of German philosophy. He attacked the “one-sidedness” of the Hegelian left-wing and denied that there was any irreconcilable conflict between Hegel and other major German thinkers, such as Schleiermacher and Immanuel Kant. Other Hegelians charged that Rosenkranz had interpreted Hegel in a Kantian way, maintaining the duality between thought and being and between the ideal and the actual. Certainly in his view the ideal was always in tension with existing conditions, although it constituted their *telos* and guiding norm. In practice, for example, he held that the church should be independent of the state; because Christianity embodies the highest ideal, the church must be free to hold before the culture its most ideal possibilities. He argued on similar grounds for the freedom of the university from political control.

Underlying religious, political, and intellectual life alike, however, was the *Volksgeist* (“spirit of a people”), interpreted more romantically than in Hegel. It is not the result of the cultural process but the distinctive psychic root of a particular people that gives the people unity as a nation and seeks expression in a total cultural life. A people is free to the extent that it fully embodies this spirit; genuine “public opinion” is the self-understanding of a free people. As a consequence, although Rosenkranz gave humankind precedence over the nation in principle and affirmed the Kantian vision of universal peace, he opposed the supranationalism of the left-wing Hegelians; moreover, he regarded their revolutionary aims as empty abstractions, without relevance to “realities” or to the concrete aspirations of any people, and productive only

of despotism. He advocated German unification, under a constitutional monarchy and through Prussian initiative, but only under a constitution that would express the German spirit. Although he vigorously opposed revolutionary change in the Prussian form of government, he just as vigorously, and at personal risk, attacked the repressive policies of its administration. For example, he defended the freedom of the press as the organ of “public opinion”; the local press, in turn, hailed him as “the most popular and liberal man in Königsberg.”

ROSENZWEIG, FRANZ

(1886–1929)

Franz Rosenzweig, the religious existentialist, was born in Cassel, Germany. From 1905 to 1912 he studied natural sciences, modern history (under Friedrich Meinecke), and philosophy (under Heinrich Rickert) at the universities of Göttingen, Munich, Freiburg, and Berlin. At Berlin he earned a doctor of philosophy degree in 1912 with a dissertation on G. W. F. Hegel's political doctrines; later, he expanded this study. In the fall of 1913, after a spiritual crisis, he turned to religious, especially Judaic, philosophy. In 1918–1919 he wrote *Der Stern der Erlösung* (*The Star of Redemption*), a three-part religio-philosophical system; in 1920 he founded the Freies Jüdisches Lehrhaus (Independent House of Judaic Studies) in Frankfurt. Two years later he was appointed lecturer for Jewish religious philosophy and ethics at the University of Frankfurt, but the onset of progressive paralysis prevented him from accepting the appointment. Despite his affliction, he continued his scholarly work until his death in Frankfurt.

Hegel und der Staat (Hegel and the state), completed in 1914, for which Rosenzweig used both published and unpublished materials, analyzes the development of Hegel's concept of the state and its place in the philosopher's system. For Rosenzweig, the reasons motivating the successive changes in Hegel's political theories are to be found in the philosopher's intellectual progression.

In "Das älteste Systemprogramm des deutschen Idealismus" (The earliest systematic program of German idealism; written in 1914), Rosenzweig established that young Friedrich von Schelling was the author of a treatise preserved in Hegel's handwriting. This treatise is Schelling's sole attempt at formulating a unified system, a feat most perfectly realized by Hegel.

Rosenzweig's own philosophy may be defined as religious existentialism. *The Star of Redemption* begins with a critique of the Western philosophic tradition and, especially, of Hegel. Rosenzweig rejected as contrary to experience the attempt to reduce to one basic essence the three elements of reality: God, the world, and man.

In German idealism it is human consciousness and thought from which both God and world are deduced. In addition, consciousness is understood as "consciousness in general," which reduces to insignificance the individual being and his separate consciousness. But thought, Rosenzweig argued, is only one of the components of existence; it does not precede existence. The significance of the individual man stems from his being alive; he is more than a part of nature or the world. In this affirma-

tion of the concrete person in his particularity Rosenzweig resumed the anti-Hegelian revolt of Arthur Schopenhauer, Ludwig Feuerbach, Søren Kierkegaard, and Friedrich Nietzsche, with its concern for the individual. The experience (*Erfahrung*) of the thinker, intent upon the value and significance of things, must guide him in confronting existence. Experience offers knowledge of God, the world, and man.

Under the influence of the later Schelling, and, to a certain degree, of Hermann Cohen, Rosenzweig links his theory of experience with a theory of conceptual construction; this linkage helps him to discover the interrelationship and interaction of the elements of God, world, and man. By way of an intricate logical construct he arrives at the following statement of relationships in terminology borrowed from theology: creation denotes the action of God upon the world; revelation, the encounter of God and man; and redemption, the relation of man to the world.

In pagan imagery God, the world, and man are separated and independent of each other. The hero of Greek tragedy is isolated from men and alien to the gods; the plastic cosmos is unrelated to man and the gods, who, in turn, have no concern for the world or man. Only biblical religion teaches the interaction of the elements of reality; in this concept, added to what he calls experience, lie the roots of Rosenzweig's existentialism. According to this view, creation is the process through which God, hitherto hidden in the mythical beyond, appears to give the world reality. But creation implies transitoriness, finiteness, death; the process of creation is renewed and perfected in revelation, through which God, in his love, turns to man; the experience of this love evokes in man the consciousness of being a self and accords man reality. Now his original isolation and dumbness are overcome; his response to God's love is his own love. Man translates his love for God into love for his "neighbor," and by so doing participates in leading the world toward redemption. Through the deeds of love the temporality of life and the finality of death are overcome. Ultimate redemption is anticipated, and a sense of eternity in time experienced, primarily in the rhythm of the days that constitute the sacred calendar in the religions based on revelation, Judaism and Christianity. Both these religions represent, under the aspect of faith, authentic, though different, manifestations of reality, and both are concerned with the existential situation of individual man.

The ideal representative of the "new thinking," as Rosenzweig called his view, is a philosopher-theologian who, while maintaining scholarly objectivity, accepts the

subjective, unique self as the new point of departure. The new theology should be existentially orientated, and theological problems should be translated into human terms. In contradistinction to abstract, timeless, purely logical, solitary thinking, the new existential thinking is “grammatical”: Human language, the word, the name, dialogue, are keys to the understanding of reality; the speaking thinker thinks *for* someone and speaks *to* someone. In such language-bound thinking, utmost importance is accorded to time; past, present, and future are actively involved in the process of thought, a notion found also in Martin Heidegger’s philosophy.

In the Judaic field, Rosenzweig advocated a reevaluation of the thought of classical Judaism. With Martin Buber he undertook to translate the Old Testament, faithfully transposing into German the style of the original.

ROSENZWEIG, FRANZ [ADDENDUM]

Rosenzweig drew heavily from the lectures of his teacher in modern Jewish philosophy, Hermann Cohen, to construct his own highly original reevaluation of the thought of classical Judaism on the model of Judah Halevi’s philosophy and poetry within the framework of the post-Hegelian, post-rationalist, German Romantic philosophy of the early twentieth century. Rosenzweig expressed his Jewish thought through many forms, including new German translations of the Hebrew Scriptures, essays on Jewish education, and his personalized administration of a nonaccredited school for Jewish studies at the University of Frankfurt. No Jewish theologian has had a more lasting impact on the subsequent development of Jewish philosophy than has Franz Rosenzweig. It is not an exaggeration to say that with very few exceptions every important Jewish religious thinker in the second half of the twentieth century was either his student or a student of his students in the United States, in Israel, and in western Europe.

ROSMINI-SERBATI,
ANTONIO
(1797–1855)

The Italian philosopher, educator, and statesman Antonio Rosmini-Serbati was born in Rovereto, then part of the Austrian Tyrol. The families of both his parents held patents of nobility under the Holy Roman Empire. A private education begun at an early age and directed to the priesthood established a firm foundation for his later work. Finding Austrian rule oppressive, Rosmini moved to the freer region of Piedmont. He started his career by founding the Institute of Charity, devoted to education and missions. He began to publish prolifically in philosophy, literature, and pedagogy. In politics he became an active exponent of the principles of Neo-Guelphism and reached the peak of his public career as counselor to Pius IX during the period from 1848 to 1853; at the end of this period, more conservative forces came to power. Retiring to private life, Rosmini continued his writing and assumed the direction of his institute. The present article restricts itself to Rosmini's philosophical work.

Although developed in a large number of works, Rosmini's philosophical thought presents a high degree of unity. This unity has two sources: the historical and apologetic intentions that sustain it and the internal development of certain germinal ideas. Rosmini's overt intention was to create a Christian-Catholic apologetics that would meet the demands of modern philosophical thought while remaining faithful to the core of traditional Christian philosophy. Since Augustinian and Thomistic realism predominated in Christian philosophy, Rosmini endeavored to anchor his thought in that tradition, exhibiting an affinity to the Augustinian strain. At the same time, he sought to meet the demands of rationalism and empiricism, and especially of the Kantian attempt at a resolution of the tension between the two. The effort to meet these conditions imparted to Rosmini's thought a high degree of complexity and sophistication.

The point of departure of the Rosminian system is his *Nuovo saggio sull'origine delle idee* (1830), a work of elaborate synthesis. The controlling principle of the synthesis is basically Augustinian, but the work develops around three centers: the idea of being, intellectual perception, and the origin of ideas.

THE IDEA OF BEING

Following Immanuel Kant, Rosmini accepted a dual order of a posteriori and a priori in the process of knowledge and identified the ground of science with a priori principles of knowledge. Whereas Kant distinguished diverse orders or forms of a priori synthesis, Rosmini reduced that plurality to a single form, the idea of being. Only the idea of being can be thought without reference to any other idea, and only that idea is thought, at least implicitly, in the thinking of any other idea. The idea of being is not the product of the subject, whether empirical or transcendental; it is a datum offered immediately by God to the intelligent subject; it is, moreover, ontologically and functionally constitutive of that subjectivity. The idea of being is both a category and a transcendental operation. It is a category, for the subject knows through the process of the existential judgment, in which being as given in the idea of being is predicated of things. This judgment establishes the subsistence of the object as present and known in the judgment.

As a category, the idea of being is the irreducible "other" to any specific content of thought or knowledge. It must also either be a product of the empirical subject or be truly objective. In the first case, the idea of being would be subjective and would render all knowledge subjective; in the second, its objectivity would seem to require the postulation of a "transcendental" subject. Rosmini accepted neither horn of this ostensible dilemma. He held that the human subject is empirical but also capable of a transcendental operation by which it can secure universal and necessary knowledge. It performs this operation through the idea of being; more accurately, this operation is one with the idea of being. As a transcendental operation, the idea of being constitutes the knowing subject ontologically and existentially; it secures the realm of universal and necessary knowledge. Finally, it is transcendent, for it is not the product of the subject, whether empirical or transcendental, but a datum that must be referred to the action of God. It is this last point that relates Rosmini's view to that of Augustine.

INTELLECTUAL PERCEPTION

Although no knowledge is possible except through the idea of being, that idea does not suffice for the effective knowledge of the actual world of determinate forms of subsistence. This world can be known only if sensation has entrance into the realm of the idea of being and vice versa. Sensation is the vehicle of the multiple forms of determinate subsistence of the real world, but it does not present them as being; for them to be presented as being, sensation must be infused by the idea of being. This infusion is achieved concretely in an operation that Rosmini called intellectual perception.

Intellectual perception is rooted in man's fundamental constitution, for he is both sentient and intelligent. Every concrete act of knowing is structured by sensation and intelligence, related in a radical unity. There is neither pure sensation nor pure intellection, or intellectual vision. Intellectual perception, in which these pure elements occur in vital union, places man in authentic contact with the concrete real world. This operation is perception because by it the subject sensibly lays hold of reality, which actually stands before it, as subsistent. It is intellectual because the sensible perception evokes in the indeterminate being, which is already present to the subject in the idea of being, determinations by which the ideas of particular things arise. Intellectual perception is not, manifestly, the synthesis of two antecedently existing elements; it is the complex term of a complex, concrete operation, rooted in the fact that man is a complex principle and subject, both intelligent and sensitive.

ORIGIN OF IDEAS

On the basis of the foregoing points, Rosmini addressed the problem of the origin of ideas. Ideas, except the idea of being, arise through the process of abstraction. Empiricists and sensationists confuse intellectual perception with sensation when they speak of the formation of ideas out of the elements of sensation through abstraction and reflection. The act of reflection is not performed on the simple sense datum but upon objects already known and present through intellectual perception. By noting certain characteristics and averting attention from others, abstraction forms ideas of various degree up to the most general. The idea of being is alone excluded from this account; for it is the presupposition, not the result, of intellectual perception.

SUBJECTIVE REALISM

Rosmini proceeded in *Psicologia* (1850) to consider the subject, which is the locus of the process of knowledge.

Here again his doctrine reflects his concern to meet both empirical and idealist claims by passing beyond them. He refused to resolve the subject into the transcendental process, as he claimed idealists did, or into the process of sensation, as he said empiricists did. Instead, he offered a “subjective realism” or, better, a “realism of the subject.” Its basis is the theory of the “fundamental sentiment,” the immediate analogue for which is intellectual perception. The soul, while retaining its classical status as the active principle of vital operations and psychic phenomena, takes on a new dimension; it is the substance-sentiment, the intuitive sense of immanent being that generates subsistence. The reality of the subject is constituted by this immediate, nonobjective, and synthetic sense of self, which draws into a subsistent unity all aspects—sensitive, intelligent, and volitional—of the subject’s complex life. This fundamental sentiment is the first and the continuous experience that man has of himself. It always involves, moreover, a relationship to a corporeal term, the body. This specific aspect of the fundamental sentiment, the corporeal sentiment, is characteristic of human nature. By it Rosmini justified the classical doctrine of man’s composition out of body and soul. All other sensations are accidental to this fundamental sentiment; it is primitive and incommunicable and constitutes the subject in its unity and complexity.

Rosmini was also able to offer a fresh form of the classical doctrine of the immortality of the soul. Immortality has its basis in the fundamental sentiment of the idea of being; through the corporeal sentiment, the body shares immortality.

THE PERSON

Important both in itself and for its function in his social and political thought is Rosmini’s central doctrine of the person. A subject has two aspects, nature and person. A subject’s nature is the complex and sum of the activities of which the subject is agent. The perfection of the subject in the order of nature is the perfection, in number and in quality, of these activities. “Person” designates the directive unity of these activities and hence is associated in a special way with the will. The will is fundamental because it directs and organizes the activities of a person’s nature, and in so doing it exhibits the basic deontic character of the person, its orientation toward a norm, toward the ought. The person emerges as the unique and incommunicable unity of the activities of the nature through a unique and unrepeatable activity of the will. It is not merely an operational or structural unity but a deontic one, basically oriented toward the world of values and

norms and hence constitutively moral. The central effort of life is the realization of the developed or explicit person, which is achieved through the exercise of moral decision within the context of nature and its diverse activities. This effort is the basis of Rosmini’s distinction between *vita diretta* and the *vita riflessa*, which is central to his moral philosophy. The central effort of the moral life is the practice of the *vita riflessa*, the examined life in a creative sense.

The elaboration of the notion of the person gives structure to Rosmini’s moral philosophy; his philosophy of right, law, and state; and his theory of education.

ETHICS

Personalism enabled Rosmini to overcome the formalism of Kantian ethics. The idea of being is the criterion of the good as well as of truth. In the intimate unity of the person, the speculative act of intellectual perception immediately translates itself into a practical judgment that becomes the legislative principle of action. The truth of being that intellectual perception presents inevitably involves the assenting activity of the will. The will seeks the being of all things in the idea of being, revealed in the deontic order as the good. Rosmini, on Kant’s model, tried to distill this insight into a rule: Recognize in action or practice what you have recognized speculatively. The essence of the moral life resides in this act of recognition, reflected prismatically in all the concrete situations in which the agent discovers himself. The obligatoriness of the rule springs from the fact that a hiatus between the speculative and the practical orders, between universal recognition and individual action, is intolerable. The psychological expression of this intolerance is remorse, the characteristic state of a person who deviates from this imperative. The true form of Rosmini’s moral philosophy is embodied in another imperative: Be faithful to being; specifically, to the being that is revealed in the idea of being and which is the ground of all.

Fidelity to being was immediately translated by Rosmini into a rule of justice. The idea of being contains all the grades of being. The realm of being thus constitutes at the same time a hierarchy of values. Fidelity to being demands that the rule of justice, “Give to each its due,” be interpreted in terms of this hierarchy. How is this hierarchy of values to be apprehended? Rosmini’s reply is that it is to be apprehended through spontaneous recourse to the intellectual light, the constitutive presence in the subject of the idea of being.

POLITICAL PHILOSOPHY

The concepts of person and justice provide the bases of Rosmini's political philosophy. Abstractly, right is the property of being, for being demands to be recognized and in doing so establishes the moral and the juridical orders. Concretely, right has its locus in the person, because of the person's ontological status as subject. In the person, right becomes a capacity to act eudaemonically, a capacity that is protected by the moral law; the same law imposes on others the obligation to recognize this capacity. Rosmini sought to bring right under the moral law in order to oppose those who would make it rest on force; he made it an endowment of the person to oppose those who would assign its origin to any other source, such as organized society in any of its forms. He distinguished innate natural rights, derived connatural rights, and acquired rights. Property, by means of which the person acquires physicomoral dominion over objects, is the chief acquired right.

While property defines the relation of the person to objects, the social bond relates him to other persons. The basis of the bond of sociality among a plurality of persons is their participation in a common intelligent principle, ideal being. Rosmini placed the forms of social life on a continuum between the terms of the most rudimentary and inclusive—membership in the human race—and the most intimate and exclusive—the conjugal relationship. Civil society falls midway on this continuum. Civil society has only a functional and not a substantive character: It does not originate rights but simply regulates the mode of their enjoyment and exercise. This provides Rosmini with his definition of the state and of government: The state is a regulatory principle of the modality of human rights. A just state achieves a balance between the common good (the good of the members distributively considered) and the public good (that of the social body considered as an organism). Abstractly, the common good is to be preferred to the public good, so as to preclude justification of acts of the state by recourse to the doctrine of "reason of state"; concretely, this preferential status is less determinate.

BEING AND GOD

In two extensive works, the *Teosofia* (posthumously published, 1859–1874) and the *Teodicea* (1845), Rosmini drew the widest possible conclusions from his personalistic premises. The theme of the *Teosofia* is the unity of being as prior to any of its modes (the absolute metaformality of being). Being, in this sense, is the basis of all the actual and determinate forms of being and contains

within itself all of the principles of that determination *in abstracto* or *virtualiter*. It is not, however, the creative principle by which those forms are reduced to actuality. The need for a creative principle opens the way for the argument of the *Teodicea*, that God necessarily exists. God is the creative principle by which the virtuality of the order of primal being is realized in the actual and concrete modes of existence.

EDUCATIONAL THEORY

The culmination of Rosmini's thought is considered by many to be his pedagogical theory. The guiding principle of this theory is a summary of his entire philosophy: respect for the human person as the vehicle of divine light and ideal being. Rosmini stressed the unity of educational process and also methodology. The person is the principle of integrity; education is the process of the realization of the person in this sense. The principle of this integration is religion, which gives unity of purpose, unity of doctrine, and unity of powers to the educational process. The supreme law of method, the principle of gradation, ensures the conformity of the process of education to that of life. The process of growth and integration according to this law is from the universal to the particular. The object of the entire process is the free and realized person who fulfills himself in free association with other persons in all social forms and whose freedom rests ultimately upon his foundation in ideal being.

ROSS, WILLIAM DAVID

(1877–1971)

William David Ross was a British Aristotelian scholar and moral philosopher. Sir David Ross was born in Scotland and was educated at the Royal High School in Edinburgh, Edinburgh University, and Balliol College, Oxford, where he took firsts in classical moderations and "greats." He was a fellow of Merton College from 1900 to 1902, when he was elected a fellow and tutor of Oriel. He was provost of Oriel from 1929 until his resignation in 1947.

Ross was prominent in academic and public life. He was vice-chancellor of Oxford University (1941–1944), pro-vice-chancellor (1944–1947), president of the Classical Association (1932), and president of the British Academy (1936–1940). He was chairman of Council of the Royal Institute of Philosophy continuously since 1940. In 1947 he served as president of the Union Académique Internationale.

Ross was awarded the Order of the British Empire for his work in the ministry of munitions and as a major on the special list during World War I. He was knighted in 1938. During World War II he was a member of the appellate tribunal for conscientious objectors and after the war was honored by the governments of Norway and Poland. Among his many public services were the chairmanships of three government departmental committees (1936–1937) and of the civil service arbitration tribunal (1942–1952). From 1947 to 1949 he was chairman of the important Royal Commission on the Press.

The qualities that made Ross successful in public life are those to which he owes his distinction as a philosopher. He was not only an Aristotelian scholar, but he also had an Aristotelian frame of mind—moderate, critical, balanced, thorough, and, above all, judicious. He valued and possessed what Aristotle called "practical wisdom" no less than speculative ability.

Ross edited the Oxford translations of Aristotle, published between 1908 and 1931. He translated the *Metaphysics* and the *Ethics* himself, and he published definitive editions of a number of Aristotle's works. His *Aristotle* (London, 1923) is mainly expository, each chapter being concerned with a major aspect of Aristotle's work; this is still the best all-round exposition in English.

Ross was the leading opponent of the view of John Burnet and A. E. Taylor that the Socrates of Plato's dialogues is never a mouthpiece for Plato's own doctrines. In *Plato's Theory of Ideas* (Oxford, 1951), Ross rejected their contention that the theory of Ideas was originally the work of Socrates and not of Plato. This book traces the

development of the theory of Ideas through Plato's thought. It includes a detailed discussion of Plato's cryptic doctrine of "ideal numbers," using Aristotle's account in the *Metaphysics* as a guide to the interpretation of the doctrine.

Ross's main contribution to philosophy, as distinct from philosophical scholarship, is in the field of ethics. In *The Right and the Good* (Oxford, 1930), he argued the case for intuitionism with a lucidity and thoroughness that made the book a classic. For some ten years it was the center of ethical controversy. In his *Foundations of Ethics* (Oxford, 1939) Ross restated his case and replied to his critics.

Ross's approach to ethics is Aristotelian. "The moral convictions of thoughtful and well-educated people are the data of ethics, just as sense-perceptions are the data of a natural science" (*The Right and the Good*, p. 41). He appeals to what we mean by rightness and goodness and assumes that this guarantees the existence of what is meant and is a sure guide to its nature.

The germ of Ross's position is to be found in an article by H. A. Prichard, "Does Moral Philosophy Rest on a Mistake?" (*Mind* 21 [1912]: 21–152; reprinted in *Moral Obligation*, Oxford, 1949, pp. 1–17). Prichard was a pupil of John Cook Wilson, who also influenced Ross directly, an influence that appears in Ross's opposition to reductionism and in his view that knowledge and opinion are distinct in kind. The other main debt acknowledged by Ross is to G. E. Moore, whose arguments against ethical subjectivism he endorses, although he rejects Moore's "ideal utilitarianism."

Right and good are for Ross distinct, indefinable, and irreducible objective qualities. Rightness belongs to acts, independently of motives; moral goodness belongs to motives. Ross uses "act" for what is done and "action" for the doing of it. Thus, the doing of a right act may be a morally bad action—that is, a right act can be done from a morally bad motive; the inverse also holds. Nor can it ever be morally obligatory to act from a good motive. There are four kinds of good things—virtue, knowledge, pleasure, and the allocation of pleasure and pain according to desert. No amount of pleasure equals the smallest amount of virtue. In *Foundations of Ethics* Ross argued that virtue and pleasure are not good in the same sense—virtue is "admirable," pleasure only "a worthy object of satisfaction." What alone is common to the two senses is that they express a favorable attitude.

Ross's two main targets are ethical subjectivism and "ideal utilitarianism," which "ignores, or at least does not

do full justice to, the highly personal character of duty" (*The Right and the Good*, p. 22). Specific duties are of three kinds—reparation, gratitude, and keeping faith. The "plain man" (to whom Ross, as a good Aristotelian, frequently appeals), in deciding what he ought to do, thinks as often of the past (a promise made, a debt incurred) as of future consequences. Ross does, however, admit among duties the utilitarian general duty of beneficence when it does not conflict with a specific duty. And "even when we are under a special obligation the tendency of acts to promote general good is one of the main factors in determining whether they are right" (p. 3a).

Conflict of duties is one of the main problems facing an intuitionist, who cannot accept the utilitarian's "Do what will produce the most good." Ross says: "Do whichever act is more of a duty." To make sense of "more of a duty," he draws a distinction between prima-facie and actual duties and holds that conflict can only arise between prima-facie duties. An act is a prima-facie or "conditional" duty by virtue of being of a certain kind (for instance, the repaying of a debt) and would be an actual duty if it were not also of some other morally important kind or did not conflict with another more important prima-facie duty. Thus, if I have promised to lend money to a friend in need, I have a prima-facie duty to hand over the money. But suppose that before I have done so, I find that I need it for the legal defense of my son, charged with a crime of which I believe him innocent. I recognize a conflicting prima-facie duty to help him. Ross maintains that (a) one, and only one, of these two prima-facie duties is my actual duty; (b) I know each of them to be a prima-facie duty—this is self-evident; (c) I can have only an opinion about which is "more of a duty" and therefore my actual duty.

ROUGIER, LOUIS

(1889–1982)

Louis Rougier, the French philosopher, was a pupil of Edmond Goblot. Rougier taught philosophy at the universities of Besançon and Caen. In 1935 he organized and presided over the Paris International Congress of Scientific Philosophy, where the leading spokesmen for logical empiricism, at the time little known in France, presented their views in a body.

From the start, Rougier’s thought had been marked by the contemporary upheavals in the sciences of physics, mathematics, and logic. To these developments he devoted several of his early books, including *La philosophie géométrique d’Henri Poincaré* (Paris, 1920), *La structure des théories déductives* (Paris, 1921), *La matière et l’énergie selon la théorie de la relativité et la théorie des quanta* (Paris, 1921), and *En Marge de Curie, de Carnot et d’Einstein* (Paris, 1922).

In his view, the upsets in the sciences reinforced the closely pressed critique which he had directed in his doctoral thesis, *Les paralogismes du rationalisme* (Paris, 1920), against the theory academic philosophers call “rationalism.” This is an a priori rationalism, quite different from scientific and experimental rationalism. It asserts the existence of a universal, immutable reason and of eternal, necessary truths, with all the theological, ontological, and epistemological implications that such a thesis requires. According to Rougier, the body of notions and principles that constitute “reason” in the classic sense is simply the characteristic of a certain mental structure, the ontological or metaphysical temperament, which is also the subject of his detailed study *La scolastique et le thomisme* (Paris, 1925). Besides the temperament dominated by “reason,” history discloses other temperaments—animistic, symbolic, scientific—having command of other types of explanation. The human mind possesses an infinite plasticity; it is able to take delight in quite varied forms of intelligibility, without any internal necessity having compelled it to evolve in just the direction that it has. If the laws of logic are necessary truths, it is only because they are tautologies in the sense

of Ludwig Wittgenstein; that is, they are devoid of any information about the universe and hence stripped of any ontological import. Even this logical necessity, as is shown by the existence of a plurality of logics, is relative to a given system of axioms and rules.

This rejection of all a priori synthesis, this radical separation between logico-mathematical statements and empirical statements, and the condemnation it entails of all metaphysics as victim of the imperfections of our natural languages (*La métaphysique et le langage*, Paris, 1960), closely ally Rougier’s philosophy to that of logical empiricism. His long *Traité de la connaissance* (Paris, 1955) offers analyses illustrated with abundant examples from the past and contemporary history of the sciences; in style and ideas it is probably closer than any other French book to the majority of central European and American works on epistemology. Nevertheless, certain features testify to his originality in comparison with the logical empiricism of the Vienna circle. Rougier rejects the physicalist reduction and upholds a plurality of languages. Nor does he agree that all basically unsolvable problems must by their nature alone be regarded as devoid of meaning; besides, meaninglessness is a notion relative to the language chosen. Further, several of the ideas he developed in works other than the *Traité*, for example his thesis of the diversity of mental structures and the plasticity of the intellect, do not strictly belong to the common stock of the school of logical empiricism, but have been added to it.

Although epistemology and the critique of knowledge are at the center of Rougier’s philosophy, he wrote in two other fields. One is the history of scientific, philosophical, and religious ideas, to which he devoted *Celse ou le conflit de la civilisation antique et du christianisme primitif* (Paris, 1926) and *La religion astrale des Pythagoriciens* (Paris, 1959). The other is contemporary political problems; he dealt critically with the democratic and egalitarian ideology of the “men of 1789” and their successors in such works as *Les mystiques politiques et leurs incidences internationales* (Paris, 1935), *Les mystiques économiques* (Paris, 1949), and *L’erreur de la démocratie française* (Paris, 1963).

Rougier systematically omitted these two aspects of his thought from the account he himself gave of his “philosophical itinerary” (*La revue libérale*, no. 33, [1961]: 6–79), an account which can well serve as an overall study of his theory of knowledge.

ROUSSEAU, JEAN-JACQUES

(1712–1778)

Jean-Jacques Rousseau, the philosopher, essayist, and novelist, was born at Geneva. His mother having died a few days after his birth, he was brought up by an aunt and an erratic father who taught him to read through the medium of sentimental novels and Plutarch's *Lives*. He had little formal education. After staying for about two years with a country minister at Bossey, he returned to Geneva and lived with an uncle. He was then apprenticed in turn to a notary and an engraver, the latter of whom treated him so brutally that in 1728 he left Geneva to seek his fortune elsewhere.

Rousseau was protected and befriended by Mme. de Warens, a convert to Roman Catholicism, who had left her native canton of Vaud to live at Annecy in Savoy, with financial support from the king of Sardinia and the ecclesiastical authorities. Rousseau's subsequent attachment to

her was a decisive factor in his conversion to Roman Catholicism as well as in his emotional development. He made a formal abjuration of Protestantism at the hospice for catechumens at Turin. He then served for a time as a lackey, finally returning to Mme. de Warens in 1729. Thereafter, he led an unsettled life, restless travel alternating with a more stable existence at Chambéry, where Mme. de Warens had established herself. Intellectually, the most important event of this phase of his life was a protracted spell of enthusiastic study under his own direction. A brief experience as a private tutor at Lyons in 1740 helped to create a lifelong interest in education and at the same time convinced Rousseau that he had no aptitude for this profession. As he had acquired some musical competence at Annecy, he set out hopefully for Paris in 1742 with a new system of musical notation. Although this did not bring him the success he hoped for, he was introduced to a number of influential people, including the wealthy Mme. Dupin and her stepson M. de Francueil.

In 1743, Rousseau was appointed secretary to the French ambassador at Venice, M. de Montaigu, but he lost this post the following year because of a quarrel with him. On his return to Paris, Rousseau increased his difficulties by an irregular union with an ignorant servant girl, Thérèse Le Vasseur, in 1745; by her he probably had five illegitimate children, who were all sent to a foundlings' home. He also met Denis Diderot, Jean Le Rond d'Alembert, and other *philosophes* and was invited to contribute musical articles to the *Encyclopédie*.

Rousseau's literary career began in 1750 with the publication of the *Discours sur les sciences et les arts*, which had previously won a prize at the Academy of Dijon. However, his first real success came with the performance of his opera *Le devin du village* before Louis XV at Fontainebleau, but his refusal to allow himself to be presented to the king lost him any chance of securing a royal pension. A journey to Geneva in 1754 led to a reconciliation with the republic and a formal return to Protestantism.

After the publication in 1755 of his *Discours sur l'origine de l'inégalité*, Rousseau felt increasingly unhappy in Paris, and in 1756 he installed himself in a small country house, called the Hermitage, which belonged to a rich friend, Mme. d'Épinay. There followed a comparatively short but intense period of literary activity that saw the publication of the *Lettre à d'Alembert sur les spectacles* (1758), *Julie, ou la Nouvelle Héloïse* (1761), *Émile* (1762), and the *Contrat social* (1762).

During this time Rousseau's relations with the Encyclopedists became increasingly strained, with intellectual differences, especially on the subject of religion, being aggravated by personal quarrels with former friends such as Diderot and the Baron von Grimm. In 1762 the condemnation of *Émile* by the Paris Parlement forced him to flee from France and settle in Neuchâtel under the protection of the king of Prussia. In the *Lettre à M. de Beaumont* (1763) Rousseau vigorously defended the "Profession de foi du vicaire savoyard," which had been included in the fourth book of *Émile*, against its condemnation by the archbishop of Paris; this was followed in 1764 by another polemical work, the *Lettres écrites de la montagne*, provoked by increasing opposition from the Genevan authorities to his political and religious views. Alarmed by local hostility, Rousseau decided to leave the Neuchâtel region in 1765, and he accepted an invitation from the philosopher David Hume to make his home in England. His arrival in that country in 1766 and his subsequent residence in Derbyshire were disturbed by the appearance of abnormal emotional and mental reactions, culminating in the irrational conviction that Hume's invitation had been a mere pretext for Rousseau's defamation. After quarreling violently with Hume (who riposted by publishing an account of the affair), Rousseau fled panic-stricken to France in 1767. For the next few years he moved from place to place, oppressed by the thought of universal persecution. He eventually settled in Paris in 1770 and died suddenly on July 2, 1778, less than two months after he had gone to live on the estate of the marquis de Girardin at Ermenonville.

The chief literary activity of Rousseau's last years was the composition of a remarkable series of personal works, the *Confessions*, on which he had worked intensively during his stay in England; the dialogues known as *Rousseau juge de Jean-Jacques*, a curiously pathological document illuminated by some pages of remarkable brilliance and insight; and the beautiful but unfinished *Rêveries du promeneur solitaire*. These writings are remarkable for their lyrical power and sustained efforts at self-analysis.

THOUGHT

From the very first Rousseau's work betrayed the strongly personal emphasis of a writer who felt that he did not truly belong to his immediate environment. Being of Genevan origin, largely self-taught, and endowed with a particularly sensitive temperament, he could never bring himself fully to accept the social and moral implications of French culture, even though he never ceased to admire French taste. In 1749, as he was on his way to Vincennes

to visit his imprisoned friend Diderot, he saw in a copy of the *Mercure de France* the subject of the prize essay set by the Academy of Dijon: whether the restoration of the arts and sciences has contributed to the purification of manners. In the *Confessions* he writes that at that moment he experienced a sudden "illumination" and "inspiration," the dazzling vision of a "new universe," which impelled him to answer the academicians' question with an emphatic "No!" Although this viewpoint was already familiar to a certain type of traditional Christian moralist, Rousseau struck a new personal note remarkable for its deeply felt sincerity; he always refused to consider himself as a professional man of letters and stressed his role as an independent writer with a message for humanity.

NATURE AND SOCIETY. Rousseau's early works (the two discourses and the *Lettre à d'Alembert*) developed the fundamental antithesis that he deemed to exist between contemporary society and the nature of man. European civilization was indicted for having sacrificed the moral demands of human nature to the superficial allure of a purely intellectual culture and thus for having replaced natural by artificial needs. The artificial uniformity of behavior that society imposes on people causes them to ignore "the duties of man and the needs of nature," so that appearance and reality are constantly at variance in modern social life, as for example in the case of an excessive regard for politeness and convention concealing the most ruthless and calculating egoism. Likewise, insisted Rousseau, the sciences and the arts, in spite of their brilliance, are not the genuine expression of fundamental human needs but the result of pride and vanity. The rapid growth of luxury and idleness serves merely to increase the corruption of the contemporary situation. Consequently, as culture appears to attain an ever increasing splendor, genuine human relationships become steadily weaker. Man is alienated from his original nature and prevented from being his real self; a perpetual prey to inner contradictions, he vainly grasps at objects outside himself as he neglects the true lessons of nature in order to pursue the illusions of opinion.

To "society" Rousseau opposed "virtue"—a constant theme of his early works. Virtue confers stability and unity upon human existence because it subordinates idle speculation to the active needs of the moral life. Unlike mere reflection, it induces "strength and vigor of soul," allowing full expression to man's genius and conferring on his existence a solidity and permanence that are quite unlike the ephemeral brilliance of contemporary culture. Whereas society forces man to assume the mask of

hypocrisy and deceit as a means of satisfying his selfish interests, virtue, “the sublime science of simple souls,” gives him an authentic openness and innocence that allow him to reveal himself to others as he truly is.

A particularly serious feature of modern society is the prevalence of an unnatural inequality based on power and wealth. In the *Discours sur l'origine de l'inégalité* Rousseau examines this phenomenon in the light of man's evolution from the primitive state to his present existence as a political being and concludes that modern conditions represent a fall from happiness into misery. In spite of its historical form, this discourse, as the author himself admits, is a purely hypothetical and imaginative reconstruction that deliberately ignores facts, whether historical or theological, in order to concentrate on the nature of man as it is revealed to Rousseau's intuitive perception. If the state of nature can never be known as a historical fact, it at least serves as a useful concept that enables him to distinguish man's original qualities from fortuitous historical accretions.

Limited and instinctive though the life of primitive man may have been, it was at least a happy one inasmuch as the savage knew how to live in accordance with his own innate needs. Leading an isolated existence in the forests, satisfying his basic appetite for food and sex without difficulty, untouched by modern man's anxiety before illness and death, he was largely self-sufficient; the primordial urge toward self-preservation was effectively counterbalanced by an innate feeling of natural pity that prevented him from inflicting needless pain upon his fellow men. Man was from the outset endowed with free will and perfectibility, but these became active only when the first rudimentary social communities, based mainly on the family, were established, a period that Rousseau treats as the golden age of humanity since it lay halfway between the brutishness of primitive existence and the corruption of political societies. The discovery of agriculture and metallurgy and the distinction between “mine” and “thine” meant that people had to work together, and this inevitably led to the establishment of property. Men then became divided into rich and poor and, later, into powerful and weak, so that the inequality of the social system was at last made permanent through the institution of laws and political organization. In Rousseau's opinion the historical process will culminate in the triumph of despotism, which makes all men once again equal because all have become slaves of one master.

Whereas the early discourses dealt mainly with general principles, the publication of d'Alembert's article “Geneva” in the seventh volume of the *Encyclopédie* in

1757, with its suggestion that the Genevans would benefit from the establishment of a theater, led Rousseau to deal with a specific aspect of his criticism of society. In his various replies to early critics he had already insisted that man, having once left the primitive state, could never return to it; he also maintained that it was the large states, especially the monarchies of Europe, which had traveled furthest on the road to perdition. However, small republics like Geneva, though no longer close to nature, still retained a relative simplicity and innocence and could be protected against further corruption. To introduce the theater into Geneva was, in Rousseau's eyes, to bring an evil product of society into a comparatively unspoiled community. The *Lettre à d'Alembert* also provided him with an opportunity of examining not only the general characteristics of the theater but also the whole question of what amusements are best suited to man's true nature.

Starting from the assumption that all valid entertainment must “derive from man's work, relationships and needs,” Rousseau insists that it must be an integral part of man's daily life, different from his work and yet inspired by the same spirit. The theater, however, is primarily an artificial entertainment, the product of idleness and vanity and the fomenter of dangerous passions and emotions; it is always subservient to the impulses that create it and remains incapable of directing people toward moral activity. The theater is typical of a large city like Paris, with its reversal of natural values. Whereas for Rousseau woman is naturally modest and self-effacing, the theater makes her a shameless figure who transforms love into a public spectacle; the very existence of actresses also sets the example of a completely unfeminine way of life that is characteristic of a society in which women set the tone and rule the *salons*, reducing men to a condition of abject and effeminate dependence. By contrast, Rousseau extols the simplicity of the Montagnons, the simple, industrious mountain dwellers whom he remembered from his youth and recalls with heartfelt enthusiasm. Unlike modern men such people relied upon their own creative resources for their work and entertainment. The Genevans, too, through their “societies” and “circles,” wisely allowed men and women to indulge in their own separate pastimes. The *Lettre* ends with a remarkable evocation of the kind of national entertainment that, in Rousseau's opinion, would be suitable for a small homogeneous community like Geneva. The Genevans should actively participate in a joyous public entertainment that takes place “beneath the sky” and in the presence of their fellow citizens; in this way the whole community would be inspired by feelings that are both social and human.

Perhaps one of the gravest general aspects of society's harmful influence on the nature of man is its constant tendency to transform *amour de soi* (self-love) into *amour-propre* (pride). Although this antithesis was not peculiar to Rousseau, who had already noted its existence in Vauvenargues, it does, occupy a particularly significant position in his social criticism. *Amour de soi* is always good and, in its purest state, quite spontaneous because it expresses the real essence of human existence. It is an absolute feeling or passion that serves as the source of all genuinely natural impulses and emotions; already revealing itself at the instinctive level as the desire for self-preservation, it assumes a much nobler expression as soon as it is combined with reason. Being in complete uniformity with the principle of order, it will affect all the main aspects of human existence as it brings the individual into contact with his own inner self, his physical environment, and his fellow men. Unfortunately modern society has changed this natural *amour de soi*, which makes a man what he truly is, into *amour-propre*, an artificial reaction originating in an anxious reflection that induces a man to be forever comparing himself with others and even finding his sole pleasure in their misfortune or inferiority; through *amour-propre* he is taken outside himself into the realm of illusion and opinion and so prevented from being a complete person.

EDUCATION. Having diagnosed the malady of modern civilization, Rousseau was faced with the task of suggesting a cure, and this led him into the domain of education and politics, activities that are, or should be, rooted in man's moral nature. Rousseau was convinced that man's original nature is good, but that it has been corrupted mainly by the historical accident of society. It therefore seemed quite consistent to affirm that men are wicked but that man himself is good. To be good is to exist in accordance with the intrinsic potentialities of one's nature, and *Émile* seeks to trace the natural development of a human being brought up in the country away from the nefarious influence of contemporary social life. From this point of view the work is not just a manual of education but, as Rousseau himself points out, a philosophical treatise on the goodness of human nature. It is less concerned with laying down the practical details of a specific pedagogic method than with describing the fundamental principles that underlie the whole of man's development from infancy to maturity. Rousseau's ultimate object is to teach the art of living, for man's first duty, he says, is to be human.

The educator must realize that "vice and error, alien to man's constitution, are introduced into it from out-

side"; his first task will be to keep away harmful influences from the young child. This is why *Émile* is set in a rural environment that allows the child to grow in accordance with his own nature. Early education is therefore largely negative insofar as it is mainly concerned with removing obstacles that might hinder this development.

From the first Rousseau stresses the importance of a progressive education: Each stage of the process must be carefully adapted to the individual's developing needs and so follow "the natural progress of the human heart." In this respect Rousseau uses in his own way the genetic method of contemporary thinkers like d'Alembert, Condillac, and Comte de Buffon, who, in turn, had taken over the notion of the genealogy of ideas developed by John Locke in his famous *Essay concerning Human Understanding*. In *Émile*, however, as in the *Discours sur l'origine de l'inégalité*, Rousseau does not strive to establish an inductive law based on the empirical examination of facts but starts from a fundamental principle (man's natural goodness) that is derived initially from personal intuition, though he believes it to be subsequently verifiable by observation and psychological analysis. *Émile* therefore involves certain metaphysical elements, but these are referred back to the concrete aspects of human nature.

Rousseau maintains that a truly progressive education will recognize that the child has his own special needs as a being who exists in his own right. "Nature wants children to be children before being men.... Childhood has its own ways of seeing, thinking and feeling." Since the child's needs are largely physical, negative education "tends to perfect the organs, instruments of our knowledge." Incapable of dealing with abstractions, the child must be educated through contact with things. To him dependence on things will be natural and inevitable; acknowledging only the "heavy yoke of necessity," he will escape the tyranny of any human will. Unlike the despotic power of men necessity is quite compatible with properly controlled freedom since it lets the human being exercise his powers within the limits prescribed for him by nature. "The truly free man" wishes to do no more than this. Well-regulated freedom thus provides the only valid basis and aim of sound education.

Early education, being based primarily on the senses, ignores bookish learning for direct contact with the physical world. Learning through a process of trial and error, the child experiments, as it were, through the medium of facts rather than words. (The sole book Rousseau will allow the child is Daniel Defoe's *Robinson Crusoe* and that only because it describes a man's reliance on his own

ingenuity and resourcefulness.) Freed from the tyranny of human opinion, the child identifies himself effortlessly with the requirements of his immediate existence; content to be himself and completely absorbed in his present being, he leads a kind of self-sufficient, timeless existence that knows no anxious concern for the future, none of that tormenting foresight that causes modern man to be so unhappily “outside himself.” The child is happy because he is unaware of artificial needs or of any serious disproportion between capacity and desire, power and will, and in this respect he resembles the happy savage.

Rousseau recognizes that even at the stage of greatest inner harmony, the child must be prepared for the future, for in him there is a reservoir of potential energy that he does not immediately need. The educator’s task is to hold back this energy, this “superfluous aspect of his immediate being,” until it can be effectively used. It is particularly important to avoid any precocious excitement of the imagination that may be the source of future unhappiness. These dangers will be largely averted if, after the lesson of necessity, the child learns that of utility, his developing reason being applied only to what interests and helps him. That is why his early judgment must be formed not through words or abstractions but through sensations and feelings.

A truly positive education begins only when the child becomes aware of his relationships with other people, although these early social lessons will be based on sensibility rather than reason, in particular on the innate feeling of pity, with its later concomitants of love and aversion. There are no good or bad passions, says Rousseau. All are good when they are under our control; all are bad when they control us. Through the force of our passions we are impelled beyond ourselves; through the “superabundance of our strength” we are induced to “extend our being.” With the growth of sensibility, reason, and imagination the child leaves the self-sufficiency of the primitive stage for a fuller life involving relations with the physical realm of nature and the world of human beings. The educational process must therefore be carefully timed and controlled so that the various potentialities of the human being are brought to fulfillment in an orderly and harmonious manner.

It is clear from the last book of *Émile* that man must be educated for society, though not necessarily for society in its present form. Man’s nature is not fully mature until it becomes social. However, the natural man in the state of nature and the natural man in the social state cannot be identical, for whereas the former is predominantly an instinctive, primitive creature living on the spontaneous

expression of his innate vitality, the latter is a rational, moral being aware of his obligations to other people, a man called upon to subordinate the impulse of “goodness” to the demands of “virtue.” Therefore, only in society can a genuinely human morality become possible. If by “nature” is meant the merely primordial responses of the presocial man, then it is true to say that “good institutions denature man” inasmuch as they raise him up from the absolute self-sufficiency of the isolated primitive state to the level of a moral, relative existence based on an awareness of the common good and the need to live in harmonious relationship with his fellow men. Since morality inevitably involves the problem of man’s life as a social being, it is impossible to separate morality and politics, and Rousseau states most emphatically that “those who want to treat morality and politics separately will never understand anything about either.” This is a most important aspect of his political thinking. If “nature” intended man for a moral existence, then it also intended him for social life; indeed, only through the individual’s participation in the “common unity” can full personal maturity become possible. “Nature” is still the norm, but one that has to be re-created, as it were, at a higher level, conferring on man a new rational unity that replaces the purely instinctive unity of the primitive state.

POLITICAL THEORY. There appears to be no valid reason for finding, as some critics have done, any fundamental contradiction between *Émile* and the *Contrat social*. Such a difficulty arises only when anachronistic attempts are made to explain Rousseau’s thought in purely individualist or collectivist terms. If at first sight *Émile* seems to be an isolated individual, this is mainly because Rousseau wanted to stress the importance of the human being’s natural development, and it in no way excludes the idea that all true education must eventually be for society.

In itself the particular form of education, like that of government, must be determined by specific historical and physical conditions, but Rousseau was less concerned with this question than with that of the fundamental principles on which all true education and all true government must be based. In this respect *Émile* and the *Contrat social* are similar since each is a theoretical, normative work. Rousseau points out in his correspondence that the *Contrat social* is a philosophical discussion of political right (the work is actually subtitled *Principes du droit politique*) rather than an examination of any existing form of government. As he says in the introduction to his work, he is taking “men as they are” and “the laws as they can be.” He seeks to reconcile “what right permits

with what interest prescribes, so that justice and utility are not divided.” In Rousseau’s eyes this is what distinguishes his approach to political problems from Baron de Montesquieu’s. Whereas Montesquieu is concerned with “the positive right of established governments,” Rousseau, as the theorist of political right, examines the philosophical basis of all legitimate government.

Although the *Contrat social* has often been described as the forerunner of totalitarianism, this interpretation is certainly not consistent with Rousseau’s conscious intention, for from the very outset his overriding preoccupation is the same as it was in *Émile*—the problem of freedom. No doubt, just as the concept of nature undergoes a radical transformation when it is applied to society, so the natural freedom enjoyed by man in the state of nature differs in important respects from the civic freedom of the social state; both, however, are natural to man at different stages of his development. Man living in society faces a problem that does not affect primitive man—namely, the possible tyranny of his fellow men. Now, a true and just society can never be based on sheer force, for right can never be equated with might. Rousseau vigorously repudiates traditional views that seek to justify the right of conquerors to subject the vanquished to permanent enslavement; no society founded on such a principle can ever be legitimate. Man’s participation in society must be consistent with his existence as a free and rational being. Society is therefore unthinkable without a freedom that expresses man’s most fundamental attribute. “To give up freedom is to give up one’s human quality: to remove freedom from one’s will is to remove all morality from one’s actions.” Moreover, it is with the emergence of society that man comes into possession of his freedom and thus attains the status of a moral being. The institution of any genuine political society must be the result of a social pact, or free association of intelligent human beings who deliberately choose to form the type of society to which they will owe allegiance; this is the only valid basis for a community that wishes to live in accordance with the requirements of human freedom.

However, there still remains the problem of finding a form of association that will continue to respect the freedom that brought it into being. Although man is naturally good, he is constantly threatened by forces that not only alienate him from himself but also transform him into a tyrant or a slave. From this point of view the political problem is not dissimilar from the pedagogic one. How is man to be protected from the tyranny of the human will? Just as the child has to be liberated from dependence upon human caprice in order to confront

necessity, so the individual is to be preserved from tyranny by “an excessive dependence” of all citizens on a new kind of necessity, on something that is greater than the citizen himself and yet in one sense a part of his life. Rousseau seeks a form of association in which “each one uniting with all obeys, however, only himself and remains as free as before.” In other words, “each one giving himself to all gives himself to nobody.” The possibility of inequality and injustice will be avoided through the “total alienation of each associate, with all his rights, to the community”; if such alienation were less than total, it would expose the individual to domination by others. As it is, the citizen does not obey some sectional interest but the general will, which is a “real force, superior to the action of any particular will.” Nor, in Rousseau’s view, need this arouse any apprehension, for unlike the individual will which concerns itself with specific and perhaps selfish interests, the general will is always directed toward the general good.

Moreover, total alienation involves equality in another way; the general will is not simply an external authority that the citizen obeys in spite of himself but the objective embodiment of his own moral nature. In accepting the authority of the general will, the citizen not only belongs to a collective, moral body but also achieves true freedom by obeying a law that he has prescribed for himself. Through the law he escapes from the bondage of appetite in order to follow, as an intelligent being, the dictates of reason and conscience. Submission to a will possessing an “inflexibility which no human force could ever overcome” leads to a freedom that “keeps a man exempt from vice” and to “a morality which lifts him up to virtue.” The individual is thereby invested with another kind of goodness, the genuine virtue of the man who is not an isolated being but part of a great whole. Liberated from the narrow confines of his own being, he finds fulfillment in a truly social experience of fraternity and equality with citizens who accept the same ideal.

This conception of political right is essentially democratic insofar as the source of all political authority and, therefore, of all true sovereignty must always lie with the people as a whole. Moreover, such sovereignty is both inalienable and indivisible since, as the basis of freedom itself, it is something that can never be renounced by the people or shared with others. However, Rousseau establishes an important distinction between sovereignty and government. The sovereign, or subjects (for “sovereign and subjects are simply the same people in different respects”), may delegate the executive function of the state to the prince, or government, which thus becomes

the agent, or officer, of the people; this is true whatever the form of any particular government, whether monarchy, aristocracy, or republic. If every legitimate government is democratic in essence, this does not mean that democracy, as a definite political institution through which the people themselves carry on the government by assembling as a body, is either possible or desirable in modern conditions. Any specific form of government, as Rousseau was to show very clearly in his *Projet de constitution pour la Corse* (1765) and his *Considérations sur le gouvernement de la Pologne* (probably written about 1770–1771), will depend on a variety of historical and geographical factors.

Law, as the act of the general will and the expression of sovereignty, is of vital importance, for the establishment of sound laws can determine the whole destiny of the state. As Rousseau observes, only the gods themselves would be capable of giving good laws to the human race. That is why the legislator has such an important role in the *Contrat social*; he is invested with a remarkable, almost divine quality. It is from him that the citizen “receives in some way his life and his being”; through the legislator’s actions he experiences a genuine transformation of his personal life, forsaking the “physical, independent existence he received from nature” for a moral existence as a social being. This new mode of existence is not something imposed upon him from the outside but a possibility elicited from the depths of his inner self. The legislator is in one respect an almost godlike figure, but his purpose is to serve the essential needs of human nature.

At the end of the final version of the *Contrat social* (though not in the original draft), Rousseau seems to acknowledge that an even more powerful sanction may be required to ensure complete political stability, for he proposes to introduce into the state a kind of civil religion or civic profession of faith to which every citizen, having once given his free assent, must remain obedient under pain of death. This is an aspect of Rousseau’s political thought that many commentators have found either shocking or inconsistent. However, it will already be clear that Rousseau is no liberal in the classical political sense since he does not believe in the possibility of any rigid separation of the individual and the state; the development of a full moral life is inconceivable without active participation in society, and the unity and permanence of the state depend, in turn, upon the moral integrity and undivided loyalty of its citizens. This civic profession of faith is deliberately restricted to the “few simple dogmas” that, according to Rousseau, every rational, moral being

ought readily to accept: belief in a supreme being, the future life, the happiness of the just, and the punishment of the wicked, together with a “single negative dogma, the rejection of intolerance.” Anybody repudiating these principles would presumably be, in Rousseau’s opinion, little more than a criminal who, by forfeiting his right to be considered as a responsible human being, threatens the state with anarchy and dissolution. The practical implications of this view may still sound alarming to a modern liberal, but they are not necessarily inconsistent with Rousseau’s ideas.

RELIGION. If the chapter “Civil Religion” seems to strike a new note in the *Contrat social*, it is certainly not incompatible with the religious emphasis of Rousseau’s thought, for religion had always played an important role in his work, as the “Profession de foi du vicaire savoyard” made clear. Nature itself must be understood in the widest sense, as the whole realm of being originally created by God, who guarantees its goodness, unity, and order. Rousseau offended traditional Christian orthodoxy with his belief that man needs no intermediary between himself and God and is able to attain salvation by his own efforts. (In spite of his great respect for the figure of Jesus and the message of the Gospels, Rousseau could not accept the notion of the Incarnation as a solution to the problem of human sin.) But Rousseau never doubted the importance of accepting God’s existence; man, he believed, is impelled toward God by the evidence of both feeling and reason, for apart from the presence of intelligence in the universe there is also the sensitive man’s deep “feeling for nature” and the inescapable conviction of a real bond uniting his immortal soul with the spiritual order that underlies the outward appearance of the physical world.

As is well known, Rousseau was the eighteenth-century writer who gave particularly eloquent expression to this aspect of the “feeling for nature.” Furthermore, apart from the testimony of reason and sensibility there is also that of the all-powerful conscience, the “divine instinct” or “voice of the soul” which forms the basis of man’s moral existence. In moments of doubt and perplexity, when all else fails man, he can always rely for guidance on the promptings of his conscience. This does not mean that reason is thereby excluded, for reason is to be condemned only when it becomes the instrument of blind passion or selfish reflection—in other words, when it fails to recognize its dependence upon other essential elements of human nature. Conscience, however, is an even more important attribute; it is a fundamental feeling that is strikingly effective when reason may be impotent.

Even so, conscience, reason, and freedom are all integral elements of man's natural endowment, potentialities that it is his right and duty to develop, for God gave him "conscience to love the good, reason to know it and freedom to choose it." It is only through the harmonious development of all man's faculties that he can come to a full understanding of his own nature and the place allotted to him by God in the universal order.

At first sight Rousseau's philosophy seems to retain many characteristics of the traditional metaphysical outlook, and several critics have stressed his great admiration for Plato and Nicolas Malebranche. In Rousseau's eyes the universe still possesses a rationality, order, and unity that reflect the wisdom and intelligence of its creator. Yet this cannot be known by reason alone, for although reason has a function in all reflection about the meaning of the world, the heart may often provide surer insights into the ultimate mystery of creation. Moreover, Rousseau's system took the form of a series of basic intuitions that he subsequently linked together into a unified whole. His thought, therefore, is imbued with a strongly personal element that excludes any purely abstract or rationalistic speculation about the ultimate meaning of reality. What concerns him is that part of reality which is identified with the nature of man. The nature of man is, of course, inseparable from nature in the wider sense, but sensibility and feeling, rather than mere reason, are probably the most effective means of penetrating this wider objective realm of being. The thinker concerned with fundamental truths will do well, in Rousseau's view, to concentrate on what is of interest to him, "interest" here being defined not in any narrowly pragmatic or empirical sense but as indicating those matters that appertain to man's original nature. This means that Rousseau finally emerges as a moralist rather than as a traditional metaphysician.

Since reflection on the nature of man involves the ability to distinguish between reality and appearance, between the genuinely original and the merely artificial aspects of existence, the thinker's first task must be to abandon the illusions of opinion for the truths of nature. This explains both the negative, critical aspects of Rousseau's views of modern society and his more positive, constructive efforts to elaborate a philosophy of man. If his interpretation of nature seemed too optimistic to satisfy the demands of contemporary religious orthodoxy, it was also too religious to please the advocates of philosophical skepticism or materialism. Of one thing Rousseau felt quite certain: To ignore or reject the profound moral and spiritual aspects of human existence could have only the most disastrous consequences for the

welfare of humanity. The discovery of truth requires an active renewal of the whole man and a reawakened moral consciousness that acknowledges the full implications of man's situation in the universe; the genuine possibilities of human life cannot be separated from the universal order of which they are a part, and man's ultimate felicity is to feel himself at one with a God-created "system in which all is good."

Like so many of his contemporaries Rousseau considered happiness to be the legitimate goal of human endeavor, but he insisted that "enjoyment" must not be interpreted in a shallow or selfish manner. Happiness consists of being oneself and of existing according to one's own nature, but a nature that has been purified of all extraneous artificial elements. When truly fulfilled, man will experience satisfaction with himself and a sense of being identified with the pure "feeling of existence"; this, in turn, presupposes the ability to find a true personal unity and plenitude. No doubt, Rousseau's efforts to realize this ideal in his own life were not free from ambiguity and contradiction, as an examination of his personal writings well shows, but his didactic works are consistent in their main objective.

In a corrupt society the recovery of a full human existence can never take the form of a mere return to nature, for the nature of man cannot be equated with the primordial state of nature. Although Rousseau was often nostalgically drawn to the innocence and simplicity of early times, he also treated nature as a dynamic, forward-looking concept. Starting from man as he is, the movement toward nature must be constantly sustained by the vision of what man might be. The achievement of this goal requires a radical transformation of human existence, the rediscovery and re-creation of a new nature. At the same time Rousseau did not believe in the need for any kind of supernatural grace to help man to carry out this task, since nature represented an innate possibility that could be realized through the wise exercise of human freedom alone.

Rousseau's powerful influence on later generations was partly due to this vision of a regenerated human nature, but unlike merely utopian thinkers he seemed to promise a transfiguration of everyday existence, not the pursuit of a hopeless chimera. Indeed, his philosophy revealed a striking, if often elusive, combination of idealistic and realistic elements that constantly seemed to open up the possibility of a better world. Moreover, this optimistic outlook was transmitted through a particularly eloquent and persuasive style, rich in emotional and musical overtones, giving the impression of intense sin-

cerity and convincing the humblest of men that he need never feel ashamed to call himself a human being.

Bibliography

WORKS BY ROUSSEAU

For bibliographical information about the various editions of Rousseau's works, though not about works on Rousseau, the reader is referred to Jean Sénélier, *Bibliographie générale des oeuvres de J.-J. Rousseau* (Paris, 1949), and Théophile Dufour, *Recherches bibliographiques sur les oeuvres imprimées de J.-J. Rousseau*, 2 vols. (Paris: L. Giraud-Badin, 1925).

Collections and Other Editions

Of the collected editions of Rousseau's works, *Oeuvres complètes de J.-J. Rousseau*, 13 vols. (Paris, 1865–1870), and *Oeuvres et correspondance inédites de J.-J. Rousseau*, edited by G. Streckeisen-Moultou (Paris, 1861), will be superseded by *Oeuvres complètes de Jean-Jacques Rousseau*, edited by Pléiade Bernard Gagnebin and Marcel Raymond (Paris, 1959–), five volumes projected. Similarly, the *Correspondance générale de J.-J. Rousseau*, edited by Théophile Dufour and P.-P. Plan, 20 vols. (Paris: Colin, 1924–1934), with the *Table de la correspondance générale*, edited by P.-P. Plan and Bernard Gagnebin (Geneva, 1953), superseded by the *Correspondance complète de Jean-Jacques Rousseau*, 51 vols., edited by R. A. Leigh (Geneva, 1965–1991).

Although the new Pléiade edition of the collected works will henceforth be authoritative, the following separate editions are still important: *Political Writings*, edited by C. A. Vaughan, 2 vols. (Cambridge, U.K.: Cambridge University Press, 1915); the critical edition of *La nouvelle Héloïse*, edited by Daniel Mornet, 4 vols. (Paris, 1925); *La profession de foi du vicaire savoyard*, edited by P. M. Masson (Paris, 1914); *Les rêveries du promeneur solitaire*, edited by J. S. Spink (Paris, 1948). For the *Confessions* see also the edition by Jacques Voisine (Paris, 1964).

WORKS ON ROUSSEAU

Some general bibliographical information about studies of Rousseau's work is to be found in Albert Schinz, *État présent des travaux sur J.-J. Rousseau* (New York: Modern Language Association of America, 1941); Jacques Voisine, "État des travaux sur J.-J. Rousseau," in *L'information littéraire* 16 (May–June 1964): 93–102; and Peter Gay, *The Party of Humanity, Studies in the French Enlightenment* (New York: Knopf, 1964), Ch. 8, "Reading about Rousseau."

A very pleasant introduction to Rousseau is Bernard Gagnebin's *A la Rencontre de Jean-Jacques Rousseau* (Geneva, 1962), a picturesque collection of texts, documents, and illustrative material. Sound general

introductions to Rousseau's thought are Daniel Mornet, *Rousseau l'homme et l'oeuvre* (Paris, 1950); E. H. Wright, *The Meaning of Rousseau* (Oxford: Oxford University Press, H. Milford, 1929), which corrects earlier misinterpretations of Rousseau's idea of nature; and J. H. Broome, *Rousseau: A Study of His Thought* (New York: Barnes and Noble, 1963), to which should be added *Rousseau par lui-même*, edited by Georges May (Paris: Éditions du Seuil, 1962), the pioneering article by Gustave Lanson, "L'unité de la pensée de Jean-Jacques Rousseau," *Annales de la société Jean-Jacques Rousseau* 8 (1912), and Ernst Cassirer, *The Question of Jean-Jacques Rousseau*, translated and edited with an introduction by Peter Gay (New York: Columbia University Press, 1954).

For Rousseau's biography see Jean Guéhenno, *Jean-Jacques*, 3 vols. (Paris: Grasset, 1948–1952), of which a new edition, titled *Jean-Jacques, histoire d'une conscience*, 2 vols., was published in 1962. See also F. C. Green, *Jean-Jacques Rousseau: A Critical Study of His Life and Writings* (Cambridge, U.K.: Cambridge University Press, 1955).

More detailed discussions of various aspects of Rousseau's philosophy are to be found in C. W. Hendel, *Jean-Jacques Rousseau: Moralism*, 2 vols. (New York and Oxford: Oxford University Press, 1934; 2nd ed., 1 vol., New York, 1962), an important examination of Rousseau's intellectual development; Albert Schinz, *La pensée de Jean-Jacques Rousseau* (Paris, 1929), which stresses and perhaps exaggerates the basic conflict between the "romantic" and the "Roman" Rousseau but is nevertheless a significant study; Pierre Burgelin, *La philosophie de l'existence de J.-J. Rousseau* (Paris: Presses Universitaires de France, 1952), an important modern synthesis of Rousseau's thought; Robert Derathé, *Le rationalisme de Jean-Jacques Rousseau* (Paris, 1948), a helpful corrective to earlier sentimentalist interpretations of Rousseau; and Jean Starobinski, *Jean-Jacques Rousseau, la transparence et l'obstacle* (Paris: Plon, 1957), an original and important study of certain key themes in Rousseau's work.

Still important for a study of Rousseau's Genevan background is Gaspard Vallette, *Jean-Jacques Rousseau genevois* (Paris, 1908), although the discussion of the Genevan aspects of Rousseau's thought has been modified by more recent criticism, especially by J. S. Spink, *Rousseau et Genève* (Paris, 1934), and François Jost, *Jean-Jacques Rousseau suisse*, 2 vols. (Fribourg: Éditions Universitaires, 1961).

Indispensable for any serious study of Rousseau's religious thought is P. M. Masson's *La religion de J.-J. Rousseau*, 3 vols. (Paris, 1916), in spite of some exaggeration of both its Roman Catholic and sentimental elements; for a corrective see Albert Schinz, *La pensée religieuse de J.-J. Rousseau et ses récents interprètes* (Paris, 1927). On Rousseau's political thought see Alfred Cobban, *Rousseau and the Modern State* (London: Allen and Unwin, 1934; 2nd ed., 1964), and Robert Derathé, *Jean-Jacques Rousseau et la science politique de son temps* (Paris: Vrin, 1950), which sets Rousseau's political thought in its contemporary philosophical context. For the difficult question of Rousseau's psychology and personality see Louis Proal, *La psychologie de J.-J. Rousseau* (Paris, 1930), and Suzanne Elosu, *La maladie de J.-J. Rousseau* (Paris, 1929). More recent discussions of this problem and its bearing on the personal writings are to be found in Ronald Grimsley, *J.-J. Rousseau: A Study in Self-Awareness* (Cardiff: University of Wales Press, 1961), and

Marcel Raymond, *J.-J. Rousseau: La Quête de soi et la rêverie* (Paris: Librairie J. Corti, 1962).

The year 1962, being the 250th anniversary of Rousseau's birth, was marked by three important international conferences whose proceedings were published: *Jean-Jacques Rousseau et son oeuvre, Colloque de Paris, 16–20 Octobre*, 1962 (Paris: Librairie C. Klincksieck, 1964); *Annales de la société Jean-Jacques Rousseau*, Vol. 35, *Entretiens sur J.-J. Rousseau* (Geneva, 1962); and *Études sur le contrat social de J.-J. Rousseau* (Paris: Belles Lettres, 1964), proceedings of Dijon conference of May 1962.

It has not been possible to include in this bibliography many important articles on Rousseau. For further information on this and other subjects, the reader is referred to the indispensable *Annales de la société Jean-Jacques Rousseau* (Geneva), published from 1905 on, which contain not only original articles but a full review of Rousseau literature.

Ronald Grimsley (1967)

ROUSSEAU, JEAN-JACQUES [ADDENDUM]

The writings of Jean-Jacques Rousseau continue to attract a wide range of readers throughout the world. Persistent questions concerning nationalism, political legitimacy, and the social costs of technological progress sustain an ongoing interest in Rousseau's major political writings (*The Social Contract*, *Considerations on the Government of Poland*, the first and second discourses). Controversies over child-rearing, the nature of language, and the role of the media in public life keep alive his educational and cultural writings (*Emile, Essay on the Origin of Languages*, *Letter to d'Alembert on the Theater*). Speculations about psychology and the arts of autobiography draw readers to Rousseau's personal writings (*The Confessions*, *Reveries of a Solitary Walker*, *Rousseau Judge of Jean-Jacques*). And new attitudes regarding love, marriage, and eroticism provoke reconsideration of his romantic novel (*La nouvelle Héloïse*). As the editors of a 1978 issue of *Daedalus* commemorating the bicentennial of Rousseau's death observed, Rousseau anticipated many of the moral, political, social, and aesthetic concerns that continue to preoccupy us today.

Three intellectual currents have contributed significantly to a growing body of scholarship on Rousseau. Feminist studies have offered fresh interpretations of his notoriously controversial writings about the nature, education, and status of women (see esp. *Emile*, book 5). Some feminist theorists (e.g., Okin, 1979) argue that Rousseau's advocacy of sexually differentiated social and political roles contradicts his egalitarian principles and

undermines the logic and validity of his political theory. Others (e.g., Weiss, 1994) maintain that sexual differentiation constitutes a necessary social construct undergirding the unity of his entire system. At issue in many of these debates are fundamental questions about the usefulness for modern feminism of any theory that posits a close connection between a woman's essential "nature" and her moral role in society.

Deconstruction has also affected the content and direction of Rousseau criticism, especially among scholars in language and literature departments. The French philosophers and literary critics who originated this movement in the 1960s and 1970s gave prime place to Rousseau in the development of their ideas (see, e.g., Derrida, 1976). In seeking to expose the indeterminacy of the meaning of Rousseau's texts by examining details that are commonly overlooked (e.g., footnotes, metaphors, his choice of particular terms), deconstructionist critiques illuminate the multilayered quality of his prose and show that even an author committed to the truth may produce writings fraught with artifice.

A third important source of Rousseau criticism has been the legacy of Leo Strauss (1899–1973)—a political philosopher who is as well known for the habits of close textual analysis he passed on to his students as for the ideas put forth in his own writings (see, e.g., Strauss, 1953). Straussian interpretations take seriously Rousseau's claims that his political thought forms a single coherent system; they also emphasize his debt to classical sources. Most important, perhaps, the Straussian legacy includes a substantial number of English translations of Rousseau's work (e.g., by Allan Bloom, Victor Gourevitch, Christopher Kelly, Judith R. Bush, and Roger D. Masters)—thus making him more accessible to the general reader in North America.

Rousseau specialists have benefited from the publication of Rousseau's *Oeuvres complètes* and *Correspondance complète*, from the appearance of scholarly journals and associations devoted to Rousseau studies (*Annales de la Société Jean-Jacques Rousseau*, *Études Jean-Jacques Rousseau*, and the *Proceedings* of the North American Association for the Study of Rousseau), and from the publication of papers delivered at various conferences held in 1978 to commemorate his death and in 1989 to mark his relationship to the French Revolution.

ROYCE, JOSIAH (1855–1916)

Josiah Royce, the American idealist philosopher, was born in Grass Valley, California. He received his AB degree from the University of California in 1875 and his doctorate from Johns Hopkins University in 1878. In the inter-

vening years he studied in Germany at Leipzig and Göttingen, where he attended the lectures of Hermann Lotze. Royce returned to the University of California in 1878 as an instructor of English. Four years later, with the help of William James and George Herbert Palmer of the Harvard department of philosophy, he was invited to Harvard, where he taught for two years as a replacement for men on leave; in 1885 he received a regular appointment as assistant professor. Until his death Royce was one of the mainstays of the philosophy department in its so-called golden period. During that time he carried on his friendly debate with William James about the merits and demerits of absolute idealism, supervised the doctoral work of George Santayana, and delivered the Gifford Lectures at the University of Aberdeen in Scotland. Royce was a prolific writer and was much in demand as a public speaker.

PHILOSOPHICAL ORIENTATION

Royce's philosophy is a unique synthesis of the rationalist metaphysic we associate with the system builders in the Western philosophical tradition and the appeal to experience and practice that has been dominant in American philosophy since 1875. Royce is the best American representative of absolute idealism, although there are voluntaristic elements in his position that distinguish it from both the Hegelian position and the systems of the British idealists. Royce's theory of the will and his conception of its role in the knowledge process introduced novel features into the tradition of rationalistic idealism. Royce was aware of this fact and hence called his position absolute voluntarism or absolute pragmatism.

Royce's thought revolves around the problems raised by a religious view of reality. He sought to resolve them through a metaphysical system constructed with the aid of concepts drawn from a wide range of thought and experience. Basic to his position is the concept of the self, an idea that he elucidated in several forms. In his earlier thought the self appears as the Absolute Knower, grasping all truth in one synoptic vision *totum simul*. Later, however, Royce put more emphasis on mediation and on the idea of system. Ultimately, he arrived at the community of interpretation, or social theory of reality, according to which all selves are joined in a Universal Community whose goal is to possess the truth in its totality.

THE NATURE OF BEING

In large measure Royce's idealism consists in his having given to the process of knowing a privileged position in the definition of reality. The nature of Being is to be

determined through the elucidation of the process of being known.

ARGUMENT FROM ERROR. The pattern of the approach through knowing was established early in Royce's development. In a paper, "Kant's Relation to Modern Philosophic Progress" (1881), he argued that the proper task of philosophy is to study the nature of experience, especially the role played by the forms of intellectual activity in knowing. In later works he returned repeatedly to the task of defining the relation between sense and understanding, between the perceptual and conceptual poles in experience and knowledge. Strongly influenced by Immanuel Kant, Royce sought to discover the exact relation between the knowing activity and its matter. He asked how the function of judgment transforms the sensible starting point of all experience into knowledge. Whereas Kant had argued that the past moment and its datum can be brought into the present through the activity of the transcendental subject, Royce regarded the past and future as projections from the present. Knowledge starts with immediate data of sense; these data, as present, are beyond the control of judgment (this is the realistic element in Royce's idealism), but the whole of experience involving reference to a past, a future, and a public object is to be built up from the momentary consciousness. In order to accomplish this construction, judgment and principles of transcendence are required.

Dissatisfied with the view that assigns the status of postulates to the principles needed for transforming immediate data into knowledge, Royce sought to justify those principles. His theory of the Absolute Knower, which he developed in the well-known chapter "The Possibility of Error" in *The Religious Aspect of Philosophy* (Boston, 1885), was intended to show that the conditions for both knowledge and error must themselves be actual; what is actual cannot be explained or justified by what is merely possible or postulated. The argument that is presented for the existence of God or the Absolute Knower may be summarized as follows. Error actually exists; erroneous judgments cannot be made erroneous by finite knowers. In order to be in error, a judgment must fail to agree with its intended object. Yet if the intended object is wholly and completely defined by the isolated judgment, it is difficult to see how the judgment can fail to be true. Royce's central contention is that a judgment can have its own object and at the same time fail to agree with it only if the judgment is not isolated as an entirely enclosed fact but is, instead, part of a system of judgments or an organized body of thought. The isolated judgment cannot have within itself the distinction between its truth and falsity;

for that we need an inclusive thought capable of relating the isolated judgment to all other actual and possible judgments about the intended object. In finding error as a fact that we cannot create, we are actually involved in the Infinite Thought. Without that Thought, error is either impossible or unintelligible. This ingenious argument assumes, among other things, that the real individual at which knowledge aims can be identified only at the end of the knowledge process. However, as Charles Peirce and others have shown, there is no need to make this assumption, although without it the argument fails.

THOUGHT AND REALITY. Royce continued to approach the problem of Being—the problem of defining the basic nature of the real—through concentration on the knowledge process. He was also trying to retain critical philosophy and neutralize its negative judgment on the possibility of ontology. His solution was to say that a theory of Being is possible if we can discover the true relation between our ideas and the real world. In *The World and the Individual* (New York, 1901–1902) Royce posed the problem of Being as one of explaining what thought and reality must be like if the former is to attain genuine knowledge of the latter. By means of an extended dialectical argument, Royce examined three classical theories of Being (in his language, theories of "the ontological predicate")—realism, mysticism, and critical rationalism. In subjecting them to critical analysis, he tried to show the element of truth and error in each. From this analysis Royce's own voluntaristic idealism emerged; it was designed to avoid the errors of the other positions while preserving their truth in a new and more comprehensive system that defined Being in terms of purpose fulfilled.

For Royce realism is the doctrine that to be is to be independent of being known. According to realism, the real is just what it is apart from the knower and his acts of knowledge. Royce, however, aimed at exposing this position and hence placed a narrow construction on the term *independent*. To be independent is taken to mean that the idea and object are totally externally related. If the idea and object are thus disconnected, he argued, then knowledge becomes inexplicable, and reality is severed from truth. Peirce, among others, objected to this statement of the realist position, describing it as one-sided.

Mysticism is defined as the thesis that to be is to be immediate. Here again, the real is understood as that which falls effectively beyond the power of analytical reason.

Royce's exposition of critical rationalism, which he defined somewhat cryptically with the formula "to be is to be valid," has been charged with ambiguity; John Dewey claimed that Royce's entire argument was vitiated by his having confused "possible experience" and "validity" in his presentation of the position. Dewey's claim is not without warrant; Royce combined several ideas under one heading, and it is not clear that they are compatible. Nevertheless, Royce's argument is clear enough in its main outline. The critical rationalist does not accept the independent objects of either realism or common sense and still less allows the immediacy of mysticism. Instead, he defines the real as that which gives warrant or validity to our ideas. To be real in this instance means that an object conforms to certain universal forms or conditions—causal sequence, temporal succession, spatial relations, numerical identity, and so on—that are marked out in advance as the general structure of all experience. For Royce the merit of this position is that it comes closer to defining reality in terms of truth than was possible with either realism or mysticism. Critical rationalism, however, is inadequate because it can define or anticipate only the universal form of experience and cannot reach the determinate individual. Royce's point is that the determinate individual cannot be defined in terms of universal conditions of possible experience alone; in order to have knowledge of an individual, we must appeal to actual, sensible experience. But it is just the need for this appeal that marks the defect of the position; a completed rationalistic idealism would show us how to pass from the idea to its fulfillment in the individual object without having to appeal to a brute, sensible experience that is "given." Critical rationalism, however, is forced to rest with "possible experience," by which Royce meant the universal conditions that any proposed object of knowledge would have to satisfy in order to be an object of experience at all. It is important to notice that the entire discussion is dialectical, in the sense that Royce expounds and criticizes the alternative theories only in relation to his own final view. Competing theories fail or succeed precisely to the extent that they are incompatible with, or contribute to the development of, his voluntaristic idealism.

VOLUNTARISTIC IDEALISM. Royce's own view can be summed up in the thesis that to be is to be the individual or determinate fulfillment of a purpose. Distinguishing between the internal and external meaning of ideas, Royce defined an idea as a purpose (internal meaning) seeking its object, or other (external meaning). An idea intends, and thus selects, its object; the object, as the full realization of the idea, must be the determinate individ-

ual that allows no other of its kind if it is to be the unique fulfillment of the purpose expressed by the original idea. If we say that Socrates is snub-nosed, our ideas (internal meaning) aim at, or intend, the unique and unduplicable individual Socrates (external meaning). Our ideas are not about just anyone or anything but only about the individual intended; the internal meaning selects the object (external meaning) by reference to which it can be judged true or false. The voluntarism of the position lies in the idea that the other at which all ideas aim is itself the expression of the absolute will or purpose. For Royce it is only in this way that we can explain how an idea can correspond with an object other than itself while that object remains other and yet is the object intended by the idea.

The entire theory is recognizable as a modern version of an ancient doctrine of self-knowledge. We start with an idea that is fragmentary and imperfectly understood, and we seek to find its true meaning in the object that is its individual fulfillment. The object intended exceeds the fragment with which we began; we can discover the true nature of the object and the truth or falsity of our idea only when we have reached the total individual reality that fulfills our purpose. Royce developed this conception of Being into a comprehensive system embracing a doctrine of man, nature, and God. The rational will and its purpose mark the ultimate reality; all finite individuality is what it is in virtue of its fulfilling the purpose of the Absolute Self.

The reality of the infinite. In the essay "The One, the Many and the Infinite" appended to *The World and the Individual*, Royce introduced the topic that was to occupy much of his later thought—the reality of the infinite. He attempted to refute the claim, made by F. H. Bradley in *Appearance and Reality* (1893), that we cannot express in clear concepts the detail of the many facts constituting the Absolute. Since such a claim, if true, would have rendered Royce's entire project pointless, he felt called upon to refute it. To explain how the many develop out of the one, Bradley argued, always leads to an actual infinity, and this is self-contradictory. In the Absolute all is one, but according to Bradley, we are unable to comprehend the unity. Royce denied that an actual infinite is self-contradictory. Through the concept of a self-representative system based on what would now be called a recursive function, he developed a modern version of the actual infinite. The form of the self-representative system was construed as a purpose or an ordering plan and defines once and for all an actual infinity of members. A self-representative system is one that represents itself with all else that it represents. A mirror of the entire universe, for

example, would have to include itself among the represented items. By the form of the system, Royce meant the principle or purpose behind it, which in the above example would be mirroring. From the one form or purpose there comes, by the recurrent or self-representative operation, an infinity of detail such that nothing less than that infinity will serve to express all that was meant by the original form. Understanding the self as having the form of a self-representative system, Royce claimed that the multitude of details constituting the concrete individuality of the real world is an expression of that self. Reality is an actual infinite, a unity of one and many. Royce's later doctrine of the community of interpretation represents his final attempt to elaborate the theory.

Logic and mathematics. It is important to note that Royce took very seriously the development of mathematical logic and studies in the foundation of mathematics. He was fond of criticizing pragmatism for neglect of what he took to be a doctrine of absolute truth implied in the new logic of Gottlob Frege, Bertrand Russell, Giuseppe Peano, and Ernst Schröder. Maintaining that "order is the fundamental category of exact thought about facts," Royce argued for the validity of using technical logical concepts in the construction of a metaphysical theory. Two examples will clarify the point. In the analysis of discrimination, he used the concept of between, arguing that discrimination and comparison are possible because, given any two conceptions, we are always able to find a third conception that is between the other two and expresses some relation in which they stand. This point was later expressed through the logic of triadic relations and the theory of interpretation. An even more striking illustration is found in the use of the limit concept to define the nature of the real as individual. The reality at which the process of knowledge is directed is said to be the "limit" of a series of attempts to apprehend the object. Royce understood "limit," not in the sense of an end term that we can approach at will, but in the sense of a least upper bound, which, in the series $1 + \frac{1}{2} + \frac{1}{4} \dots$, for example, is the least number that lies beyond the sum of the series—namely, 2. Thus, the real, individual reality is what is immediately beyond the whole series of efforts to know it.

ETHICAL AND RELIGIOUS DOCTRINES

Royce contributed ideas worthy of consideration to almost every branch of philosophy, not least in ethics.

LOYALTY. Royce's *Philosophy of Loyalty* (New York, 1908) is still one of his best-known books. In it he developed the

principle of loyalty to loyalty as the basic moral law. He regarded his principle as superior to both Kant's categorical imperative and J. S. Mill's principle of utility. Loyalty, by which is meant a freely chosen and practical devotion to a cause or goal, is the highest virtue. Royce was well aware of the existence of evil causes and of the fact that not every cause aims at the loyal spirit. Hence, he argued that loyalty in the ethical sense means devotion to causes that extend the spirit of loyalty and do not contribute to deception, dishonesty, racial and social strife, and so on. Every cause involves some loyalty, but not all causes involve loyalty to loyalty. It is only through loyalty to loyalty itself, the virtue that makes all social life possible, that the self can solve the basic problem of ethics, which is to find a good that is at once objective, in the sense that it constrains our purely individual and subjective interests, and freely chosen, so that the self can acknowledge its obligatory character. Royce followed G. W. F. Hegel in finding the good in a form of self-realization, and he followed Kant in upholding the autonomy of the will.

PHILOSOPHY OF RELIGION. Royce's interest in the philosophy of religion was a basic factor in the shaping of his philosophical position. Religious issues constitute the foundation of his thought, starting with *The Religious Aspect of Philosophy* (Boston, 1885) and continuing to his last major work, *The Problem of Christianity* (New York, 1913). Royce had a twofold aim in the philosophical treatment of religion. First, he sought to reinterpret classical religious ideas through contemporary experience and current language; second, he attempted to assess their validity by comparing them with the results of metaphysical analysis. Both aims are clearly present in *The Problem of Christianity*, in which he developed an original interpretation of the Christian religion, first, by uncovering the experiential roots of three central ideas—the church, sin, and atonement—and, second, by seeking support for these ideas in his metaphysics of interpretation and community.

Starting with the view that neither perception nor conception alone, nor any indeterminate combination of the two, is able to yield knowledge of selves, Royce went on to develop the theory of interpretation, according to which all our knowledge is mediated through signs. From this view it follows that the human self is not known (either by itself or another) intuitively as a particular datum or as a universal character but only as the goal of an infinite process of interpretation. In requiring comparison with other selves, this process necessitates a community if there is to be self-knowledge. Persons are involved in, and linked together by, a number of different

communities—political, legal, economic, moral, religious—each of which is defined by its purpose or the goal for which it exists. The religious or Beloved Community has the special purpose of redeeming man from sin (a moral burden) and from the consequences of the self-centered deeds by which he endangers the community through disloyalty. The three central ideas of Christianity (the church, sin, and atonement) are linked together. The Beloved Community is the locus of the love (in Royce's terms, loyalty) exemplified by the atoning deed of Jesus; the church exists to overcome, through love, the self-centeredness of the individual and to transmute the evil consequences of treachery by a constant renewal of the community of many selves devoted to the cause of charity.

The novel feature of Royce's reinterpretation of Christianity is his attempt to rework the much neglected doctrine of the Spirit, or Third Person, of the ancient Trinitarian tradition. God now appears as the Spirit or Interpreter, linking together a multiplicity of distinct selves in a spiritual unity of love. The Beloved Community, founded by the sacrificial or atoning deed of Jesus, becomes the ultimate instrument of the redemptive process.

Unlike William James, Royce was clearly dissatisfied with a purely practical basis for religious belief. Instead, he made the validity of religion dependent on a metaphysical system. He set forth one such system in *The World and the Individual*, and he returned to the task in *The Problem of Christianity*, in which he dealt with specifically Christian ideas. In the intervening years Royce fell under the influence of Peirce's thought, and he freely acknowledged an indebtedness to Peirce's theory of signs, his analysis of triadic relations, and the idea of the community of knowers engaged in interpreting the meaning of things through an infinite system of signs.

The continuation of the logical and epistemological aspects of Royce's philosophy is to be found mainly in the work of C. I. Lewis, and its metaphysical aspects are developed in the thought of W. E. Hocking. The strong current of pragmatism on the American scene, however, carried philosophical thinking away from the speculative realm and directed it into other channels.

ROYER-COLLARD, PIERRE PAUL

(1762–1845)

Pierre Paul Royer-Collard, the French statesman and professor of philosophy, was born at Sompuis, a village in what is now the department of the Marne. He represented this department in the Chamber of Deputies from 1815 to 1839, usually in the opposition. He is best known as the leader of the *Doctrinaires*, a group whose members derived their political views from what they believed to be immutable and self-evident principles. These principles led to a compromise between absolute and constitutional monarchy, and though the principles were supported by Louis XVIII, they were rejected by his brother and successor, Charles X.

Royer-Collard had little, if any, philosophical training. Nevertheless, from 1811 to 1814 he was professor of philosophy and dean at the Sorbonne. He lectured first on Thomas Reid and later on his own views. Just as his political views were a compromise, so in philosophy he sought a compromise between the left wing of sensationalism and the right wing of authoritarian traditionalism. He found it in the philosophy of Reid. Royer-Collard rejected sensationalism on the ground that it could not account for judgment, which is always something contributed to sensory material by the active mind. Since the individual mind is active and capable of making judgments, there is no need of a supernatural authority to dictate to it. In place of such an authority he substituted common sense, which is a consolidation of the judgments of all men. But this did not imply a return to tradition except insofar as tradition itself is an expression of common sense. On the contrary, every man has within him the ability to distinguish between right and wrong, truth and falsity, by a power that resembles the natural light of medieval philosophy. If this faculty did not exist, he maintained, one would be stranded in solipsism, for there would be no reason to believe that one man's conclusions would be harmonious with another's.

Common sense, however, does not operate entirely without the guidance of reason. In reaching its decisions, reason uses two principles of argument, that of causality and that of induction. The search for causes is intrinsic to thinking itself and will inevitably lead back to the idea of a First Cause. For, following Isaac Newton, Royer-Collard believed that one must never accept more causes than are necessary to explain phenomena. However, he does not

seem to have had any clear idea of the nature of a causal explanation.

The principle of induction is a necessary accompaniment to that of causality, for it is by induction that one discovers the essential similarities among phenomena that permit one to group them in a single class. It is man's nature to look for these similarities, as it is his nature to look for causes.

Following Reid, Royer-Collard maintained that the distinction between sensation and perception is all-important. Sensation is simply the pleasure found in experience and is purely subjective. Perception is the apprehension of an external object as external. The externality of the object is not proved by reasoning; it is judged by a spontaneous act of the human mind, as in the twentieth-century epistemology of G. E. Moore.

Though only fragments of Royer-Collard's philosophy exist, collected by his admirer Théodore Jouffroy, it is probable that he saw the philosophy of common sense as a support for his political views. Common sense is the basis of communal life; it provides stable theses of morality and religion; it has all the authority of natural law; and to those who accept it, it is incontrovertible. It is, however, generally admitted that the main contribution of Royer-Collard to French philosophy was the introduction into France of Scottish philosophy.

ROZANOV, VASILII VASIL'EVICH

(1856–1919)

Vasilii Vasil'evich Rozanov, the Russian critic and philosopher, was born in Vetluga, Russia, and attended secondary schools in Simbirsk and Novgorod before entering Moscow University as a student in the faculty of history and philology. After his graduation from the university in 1881, he taught history and geography in a succession of secondary schools in provincial towns and began the writing on religious and philosophical themes that was to gain him a reputation as a brilliant if erratic critic of contemporary culture, both secular and religious. In 1893 a minor government post in St. Petersburg brought him to the center of Russian literary life, and in 1899 he retired to devote full time to writing. He published numerous books and contributed many articles to the Russian reviews of the day, particularly the reactionary *Novoe vremia* (New times). During the Russian Revolution he took refuge with the religious philosopher Father Pavel Florenskii in Sergiev Posad, near Moscow, where he died.

Rozanov's first major writing and his only strictly philosophical work was an elaborate scholarly treatise titled *O ponimanii* (On the understanding), in which he developed a conception of understanding as a unifying mode of cognition that reconciles science and philosophy. He first won public acclaim with his critical study of Fëdor Dostoevsky, *Legenda o Velikom Inkvizitore* (The legend of the grand inquisitor). In a number of impressionistic, aphoristic works written from 1911 to 1918 he developed most fully the critique of Christianity and the "metaphysics of sex" for which he is best remembered. Chief among these later works are *Opavshie list'ia* (Fallen leaves), *Uedinennoe* (Solitaria), and *Apokalipsis nashego vremeni* (The apocalypse of our time).

Rozanov's mature worldview was a mystical theism based on the sanctification of sex. Emphasizing the generative power of sexuality, Rozanov saw in it the aspect of man that relates him most intimately to God. Sexuality is man's "noumenal aspect," of which his other qualities and capacities are manifestations. Rozanov vigorously attacked Christianity for its denial of the flesh in preaching celibacy and fasting and for its failure to recognize the holiness of elementary animal processes. He preferred the religion of the Old Testament because of what he regarded as its greater acceptance of life and greater humanitarianism, and he called for renewed worship of the vital biological forces enfeebled by Christianity.

ROZANOV, VASILII VASIL'EVICH [ADDENDUM]

Since the late Soviet period and especially since the collapse of the USSR, Vasilii Rozanov has been one of the most popular and influential thinkers of the religious-philosophical movement of the early twentieth century. His playful and artful texts, at once pungent and profoundly self-conscious, have provided an example of Russian postmodernism *avant là lettre*. He has had a noticeable impact on recent Russian literature (most notably Andrei Siniavskii [aka Abram Terts], Venedikt Erofeev, and Viktor Erofeev) and philosophy (Vladimir Bibikhin). A collection of Rozanov's works, numbering eighteen volumes by the end of 2004, includes many of his published books, scores of uncollected essays, and a wealth of previously unpublished material, including several volumes in the genre of "fallen leaves" (*Sakharna*, 1913; *Mimoletnoe* [Transitory things], 1914 and 1915; *Poslednie list'ia* [Final leaves], 1916 and 1917) and the greater part of texts written for *Apokalipsis nashego vre-*

meni (The apocalypse of our time), left unpublished at his death.

Rozanov's flouting of conventional philosophical methods and genres has generated challenging insights in the face of rapidly changing circumstances and intellectual currents. In particular, his phenomenological observations and reflective self-analysis provide an incisive commentary on the interaction between the self and the modern world in such areas as nature, women's fashion, sex, Christianity, and Judaism. In his essay "O sladchaishem Iisuse i gor'kikh plodakh mira" (On sweet Jesus and the bitter fruits of the world, 1907) Rozanov scandalized Russian orthodoxy by condemning its denial of worldly values. In *Ital'ianskie vpechatleniia* (Italian impressions, 1909) Rozanov used the persona of an estranged and bemused Russian tourist to analyze the legacy of roman antiquity and the place of religion in modern Western civilization. Even his first book *O ponimaniï* (On understanding), a spectacular flop upon publication in 1886, has been revisited for its more systematic exposition of ideas that Rozanov later developed in his prolific journalistic work.

There has been considerable interest in Rozanov's Aristotelian concepts of potentiality and teleology, and his quest for a holistic form of knowledge more closely attuned to living reality. For Rozanov, cognition cannot be strictly separated from the reality it constructs; long before existentialism, Rozanov declared existence to be prior to essence. He maintains that the philosopher's task is to describe the interaction between the active percipient and his object in all of its complex existence; only in this way can one access and activate essences. Of especial interest is Rozanov's insistence that a particular kind of sympathetic attention is needed to unleash the potential of the inert forms of life. These themes—reality as dependent upon human interaction and history as the process of human understanding—associate Rozanov with the hermeneutic tradition in European philosophy and inspired his turn to an original, narrative style of philosophy in his books of the 1910s. The significance of Rozanov's thought for philosophical aesthetics and the philosophy of religion has only recently begun to be explored.

Rozanov's writings on sexuality (including homosexuality) and Judaism have become only more controversial with time. While Rozanov verged on outright antisemitism in his political commentary, he also professed profound admiration for Jewish traditions of kinship, coupled (especially in his final writings) with increased hostility toward Christian asceticism. His veneration of

fertility caused him to oppose homosexuality, although his frank discussion of the matter rankled with traditionalist allies. Some attempt has been made to cast these writings as “carnivalistic” and “dialogic” (both terms stem from the discourse philosophy of Mikhail Bakhtin): Rozanov is seen as exploring various voices and inverting social conventions in order to overcome the manifest conflicts in society at the level of discourse. Continuing this theme of dialogism, Rozanov’s correspondence (which he often cited in his essays) and his broader intellectual exchange with such leading figures as Konstantin Leont’ev and Pavel Florenskii shed much light on the broader philosophical discourse of his day. As new texts come to light and his entire project is more fully understood, interest in Rozanov’s work will likely continue to grow.

Robert Bird (2005)

RÜDIGER, ANDREAS

(1673–1731)

Andreas Rüdiger, the German physician and philosopher, was born in Rochlitz, Saxony. Poverty and bad health allowed him to study only irregularly. In 1692 he served as a tutor in the home of Christian Thomasius. He was compelled to interrupt his studies completely in 1695; not until 1697 could he enter the University of Leipzig, where he studied law and medicine, receiving a master’s degree in 1700. He received a doctorate in medicine from the University of Halle in 1703, but he continued to lecture at the University of Leipzig. From 1707 to 1712 he practiced medicine and lectured in Halle, and from 1712 until his death he did so in Leipzig.

The development of Rüdiger’s philosophy was greatly influenced by his teachers Christian Thomasius and Franz Budde. However, he soon developed individual views within the Thomasian school. His medical studies centered his interests on natural philosophy and gave his thought a practical bent. Like Budde’s, Rüdiger’s mind was more systematic than Thomasius’s.

Rüdiger’s most important work, *Philosophia Synthetica* (1706–1707), is divided into three sections: “Wisdom,” “Justice,” and “Prudence.” The section on wisdom embraces logic and natural philosophy, that on justice

covers metaphysics and natural law, and that on prudence covers ethics and politics.

Rüdiger's logic had a clear psychological orientation. He was mainly interested in the origin and development of our ideas, which, he held, come into our minds through the senses, although there are some innate mental elements, too. He criticized René Descartes, discussed Pierre Gassendi, and drew some inspiration from John Locke. Rüdiger stressed the passive element of the mind; reflection, or *sensio interna*, is (contrary to Locke) a passive fact. The standard of truth lies in man's consciousness, in a *recta ratio*, which is not common sense but something that can be acquired only through instruction in logic (*lumen acquisitum*). Logic was therefore more important for Rüdiger than for the other members of the Thomasian school. He developed a refined syllogistic theory, formalizing his acceptance of the mathematical method in philosophy. However, he conceived the mathematical method quite differently from Christian Wolff, as a method for deducing facts from given facts rather than as the drawing of possible conclusions from abstract principles. Rüdiger's philosophy, like that of the Thomasian school generally, was based in large part on the notion of reality and appealed mainly to the senses and to experience, both interior and exterior. He defined "truth" in connection with the possibility of perceiving and "existence" in connection with being perceived—again in the tradition of Thomasian subjectivism.

In natural philosophy, Rüdiger tried to combine the Thomasian and Pietistic animistic or spiritualistic physics with mechanism, but the spiritualistic element predominates. He held that we have no certain knowledge of nature, and generally he refrained from choosing between different hypotheses, for instance, between the Copernican and the biblical astronomical theories.

The practical bent of Rüdiger's philosophy explains why he discussed metaphysics under the heading of justice. His metaphysical discussions were largely devoted to theology and to man's duties toward God; his discussions of natural law were devoted to our duties toward other men. Metaphysics is the science of reality, and in particular of the *ens realissimum*, rather than the science of possibility. However, according to Rüdiger, we cannot penetrate the essence of things in metaphysics; we can only establish, by means of experience, that things exist and how they exist.

Rüdiger's section on prudence constitutes, in the Thomasian tradition, a kind of anthropology, both private and public. Ethics provides precepts for reaching

happiness on Earth, and politics provides precepts for governing a commonwealth.

Through his pupil A. F. Hoffmann, Rüdiger exerted a strong influence on the development of the philosophy of Christian August Crusius, and through Crusius on the whole development of German philosophy.

Giorgio Tonelli (1967)

RUFUS, RICHARD

(?–after 1259)

Richard Rufus, a thirteenth-century philosopher and theologian, was among the first European medieval authors to study Aristotelian metaphysics, epistemology, and natural philosophy. His lectures on the so-called *libri naturales* date from a period shortly after the effective lapse of the ban on teaching them in 1231 and are among the earliest European commentaries on those works. In 1238, after writing treatises against Averroes and lecturing on Aristotle—at greatest length on the *Metaphysics*—he joined the Franciscan Order, left Paris, and became a theologian.

Rufus's lectures on Peter Lombard's *Sentences* were the first presented by an Oxford bachelor of theology. Greatly influenced by Robert Grosseteste, Rufus's Oxford lectures were devoted in part to a refutation of Richard Fishacre, the Dominican master who first lectured on the *Sentences* at Oxford.

Rufus's Oxford lectures were employed as a source by St. Bonaventure, whose lectures on the *Sentences* were vastly influential. Returning to Paris shortly after Bonaventure lectured there, Rufus took Bonaventure's lectures as a model for his own Parisian *Sentences* commentary. Rufus's Paris lectures made him famous. According to his enemy Roger Bacon, when he returned to Oxford after 1256 as the Franciscan regent master, his influence increased steadily. It was at its height forty years later in the 1290s, when John Duns Scotus was a bachelor of theology. Early versions of many important positions developed by Duns Scotus can be found in Rufus's works.

NATURAL PHILOSOPHY

Among the first medieval European philosophers to encounter Aristotle's arguments for the eternity of the world, Rufus also presented some of the most cogent counterarguments. One argument is based on a contradiction between the definitions of *past* and *infinity*. It is impossible to traverse an infinity, but it pertains to the nature of the past to have been traversed; therefore, past time cannot be infinite. In 1235 Rufus presents the argument with characteristic brevity: "Having been traversed" is incompatible with the definition of infinity, but "having been traversed" belongs to the definition of the past. Therefore, being past is incompatible with the definition of infinity.

This argument, first presented in late antiquity by John Philoponus, is now associated with Immanuel Kant; in medieval philosophy it is ordinarily ascribed to Bonaventure, who advanced it in 1250 or 1251. It occurs in different versions, some more persuasive than others. Grosseteste, for example, mistakenly seeks to apply it to the future as well as to the past, claiming that the argument can be used to show that time could not be infinite *a parte post*. Rufus sees even more clearly than Philoponus that the direction of time is an important part of this argument. He notices that the argument must be based on the fact that the whole of past time has been traversed, rather than on the claim that the whole of the past and the future will have been traversed. In his later work he seeks to force his opponents to see that they are committed to the claim that some past days are not now and never were present. By contrast, Philoponus sees this as an argument about the impossibility of completely

counting an infinite series, with no particular focus on the direction of time.

Rufus's version of another of Philoponus's arguments is based on the concept of priority. If the number of days before today is infinite, and the number of days before tomorrow is infinite, then the number of days before today is not less than the number of days before tomorrow. Consequently, today does not arrive sooner than tomorrow, which is absurd. Rufus assumes here that unequal infinities are impossible. Following Georg Cantor, modern mathematicians reject this assumption. However, Rufus needs only the uncontroversial claim that mappable infinities are equal: If one postulates beginningless time, the number of days before today and the number of days before tomorrow are mappable infinite series. Rufus might still argue that if the world has no beginning, then one must give up the belief that less time elapses before earlier events than before later events.

Philoponus's original version of this argument is not based on the claim that more time transpires before later events than before earlier events. The absurdities he asks one to reject are mathematical: that it is possible to add to an infinity, or that one infinity can be multiplied by another, so that one infinity would be greater than another by a determinate proportion. By contrast, the absurd conclusion Rufus asks one to reject is that "today does not come sooner than tomorrow"; he emphasizes the unique properties of time.

THEORY OF KNOWLEDGE

The fullest statement of Rufus's epistemological views now known is a treatise titled *Speculum animae* (A mirror of the soul), probably written to explain problems in Aristotelian philosophy to his Franciscan confreres. This treatise addresses the question: What does Aristotle mean when he says that "in some manner the soul is every thing"? In the *Speculum* Rufus develops and changes his views; he rejects the view his predecessors based on patristic authorities: The soul is everything because it shares being with rocks, life with animals, and understanding with angels—a view Rufus states without comment in the last lectures he gave before becoming a Franciscan, when expounding *Metaphysics* Lambda. Since Rufus also rejects a literal interpretation of the dictum, he must explain in what sense the soul becomes an object when it understands or senses that object.

Rufus has to face two related questions: Why does the soul not become green when it perceives something green? If reception of species produces apprehension in the soul, why does the presence of such species not have

this effect in other subjects? One element of Rufus's reply is constant. He postulates that sensible and intelligible species are nonnatural and different in their mode of being from external objects. Such species are not described by Aristotelian categories; they are neither substances nor accidents. Accordingly, their reception does not produce the object sensed but the sensation or cognition of the relevant object; the sensitive soul does not become green; it senses the color green. In his *De anima* commentary Rufus describes the direct objects of sensation as spiritual beings, and he holds that plants do not sense colors since spiritual beings do not act on them. Spiritual being, a concept Rufus owes to Averroes, is the key to Rufus's exposition of a phrase in Aristotle, who says that the senses are susceptible of sensible species "without matter" (2.12.424a18–19). In his *Contra Averroem* Rufus confronts the objection that accidents that are not spiritual also act without matter—in producing heat, for example. He replies by claiming that Aristotle was contrasting species or intentions with "materiated species" designed to perfect matter rather than to produce cognition. In his last *Metaphysics* commentary Rufus contrasts spiritual with material reception, repeating terminology from his *In De anima*, but omitting the *De anima* commentary's reference to spiritual being.

In his *Contra Averroem* Rufus also makes it harder to answer the second question in another respect. Lecturing on *De anima*, Rufus claims that wood, for example, apprehends nothing because its matter receives only the natural form of wood, not its species (a similitude of the whole). In *Contra Averroem* he cites passages that convince him that the objects one senses are not mere similitudes of sensed objects but really the same as them. Rufus's response to the problem this presents in the *Speculum animae* (and subsequently in his Oxford theology lectures) is to argue that what is really identical may be formally distinct. Since species exist nonnaturally, they can be really the same as, but not formally identical with, or predicable of, the objects of apprehension. This safeguards the claim that what one apprehends is really the same as external objects; in some sense the soul really is all things.

METAPHYSICS

Postulating a kind of identity that permits real but not formal predication is a conceptual tool that Rufus employs when discussing a variety of philosophical topics—for example, the problem of individuation. Like Duns Scotus in his *Metaphysics* commentary, Rufus postulates individual forms to explain individuation. Indi-

vidual forms are really, but not formally, the same as specific forms. Specific forms are principles of shared identity; they pertain to common natures capable of instantiation (*multiplicabilis*). By contrast, individual forms pertain to the same natures as they are actually instantiated (*actu multiplicata*).

Rufus's arguments against alternative theories were initially more influential than his own views. He holds that the cause of individuation cannot be an accident or an aggregation of accidents, since individual primary substances are ontologically prior to accidents. Though he allows a role for matter as an occasional cause of individuation, he argues that even determinate matter could not by itself be the principle of individuation. Being an individual means being distinct and united, both of which are functions of form, the active principle of substance, not matter, the passive principle.

Holding that individual forms added to an aggregate of matter and specific form must be the principle of individuation, Rufus denies that the ultimate constituents of individuals are knowable. He is not sure whether what is added to the common nature can be located within an Aristotelian category. He suggests that, strictly speaking, the cause of individuation may be neither a substance nor an accident. Identifying individual forms as perfections of the specific form, he suggests that they may be substantial without being substances. Specific and individual forms provide different degrees of unity: Specific unity is less than individual unity and greater than generic unity.

Like Rufus's views on individuation, his argument for the existence of God was accepted and modified by Duns Scotus. Rufus rejected St. Anselm's famous ontological argument as sophistical (though subtle). In its place he advanced a modal argument based on the concept of God as an independent being (*a se et non ab alio*). The existence of independent beings is either necessary or impossible. Therefore, if an independent being can exist, it does exist. Rufus employs logically sophisticated arguments to show that an independent being can exist.

At the opposite end of the cosmological scale, Rufus also makes an original contribution to the problem of elemental composition—positing elemental forms incompletely actualized in the compounds they comprise. Rufus sets out to explain how elements can retain their identity in a compound, so that we can correctly say that a compound is composed of elements, and yet also explain the unity of the compound with a distinct identity. Rufus has to describe how flesh and bone can be composed of elements that can be separated out when the compound breaks down, without immediately being dis-

solved by their component elements' actions on one another—the hot heating the cold, for example. If there is to be a compound at all, the elements cannot exist in the compound in quite the same way that they do when separated. Supposing that the elements are substances, Rufus argues contrary to Averroes that elemental forms are in no sense accidents, either in the compound or outside it, though they are subject to intension and remission. His solution to the difficulty is to postulate that the elemental forms can be more or less actual; they exist in compounds in accidental or proximate potential, prevented from complete actuality by the presence of the contrary elements. The resulting mixture Rufus describes as having the unity of fusion, intermediate between absolute unity and unity of aggregation.

INFLUENCE

Rufus's importance has long gone unrecognized, in part because he preferred not to take credit for his own work and in part because, unlike his contemporaries, he provided long quotations of the positions he treated seriously. Since his own views were often stated briefly, historians who overlooked his critical bent saw him as a derivative figure. Now that Bonaventure's borrowing from Rufus has been discovered, and scholars are beginning to appreciate the significance of citations by Grosseteste (to Magister Richardus), Duns Scotus (to *Doctor antiquus*), and Franciscus de Marchia (to Richardus), the question of Rufus's influence will have to be reconsidered.

Rega Wood and Jennifer R. Ottman (2005)

RULE FOLLOWING

In 1982 Saul Kripke published *Wittgenstein on Rules and Private Language* and ushered in a new era of Ludwig Wittgenstein interpretation. Although elements of Kripke's view of Wittgenstein could be found in the preceding literature (notably in Robert Fogelin's *Wittgenstein*), nothing had captured attention like his presentation of the "rule-following considerations."

Kripke presented his essay as a reconstruction of the problems Wittgenstein is addressing between around §140 and §203 of the *Philosophical Investigations*. These issue in the form of a paradox—that there can be no such thing as the meaning of a word; no fact of the matter that entails that a word is used according to a rule, whereby some applications of it are determined to be correct and other applications incorrect. In §201 Wittgenstein wrote "This [is] our paradox: no course of action could be determined by a rule, because every course of action can be made out to accord with the rule. The answer [is] if everything can be made out to accord with the rule, then it can also be made out to conflict with it. And so there would be neither accord nor conflict here."

The paradox is developed by Kripke through the figure of a "bizarre skeptic." The defender of common sense, here the view that words do indeed have meanings and obey rules, is challenged to show what this meaning consists in. The facts he or she can adduce typically include past applications and present dispositions to apply words in new cases. They may also include flashes of consciousness—for instance, if we associate a particular image with a term. But, Kripke's skeptic argues, these are not the kinds of facts that can determine the actual rule that governs the meaning of a word. The skeptic adduces three kinds of problems. First, our dispositions are finite, whereas a rule can cover a potential infinity of new cases. Second, our dispositions sometimes fail to match the relevant rules: This is precisely what happens when we mistakenly apply words to things to which they do not in fact apply. Third, the existence of a rule has normative implications. It determines correctness and incorrectness of application of the term it governs. Our dispositions, by contrast, have no such implication. There is nothing intrinsically wrong about bending our dispositions from moment to moment, in the way that there is about applying a term in a way that fails to accord with its meaning. Finally, the addition of flashes of consciousness is unlikely to help, for, as Wittgenstein himself said, any such fact itself stands in need of interpretation. A flash of consciousness cannot comprehend all the possible appli-

cations of a term and sort them into those that are correct and those that are not.

Kripke illustrates these points with the case of a strange arithmetical operator, “quus.” For two numbers n and m , n quus m is identical with n plus m for sufficiently small or common numbers, but the two results (or calculations) diverge when n and m are greater than a certain value (the function is therefore reminiscent of Nelson Goodman’s predicate, “grue”). We do not mean n quus m when we talk of n plus m . But our dispositions with “plus” might match those of people who in fact use the term to mean quus; we might give the answer n quus m when we attempt to add n and m , since we make mistakes; and finally there is nothing right or wrong about having one disposition or another.

The conclusion is paradoxical, since nothing seems more certain than that we do succeed in attaching reasonably determinate meanings to terms. It may be true that the “open texture” of terms suggests that meanings are never fully precise, capable of determining their application in any circumstances, however outlandish. Nevertheless, over an indefinite normal range of cases, there is no doubt that some applications are correct and others not, and any interpretation of us according to which we mean something along the lines of the “quus” function is incorrect. Yet so long as the skeptic wins, we have no conception of our right to say such things. Kripke’s own solution to the paradox is that the skeptic wins on his chosen ground. There is indeed no fact of the matter whether one rule rather than another governs the use of a term. But we can advance a “skeptical solution” (David Hume’s phrase from a different context) to the doubts. What there is instead is a practice of regarding ourselves and others in certain lights. We dignify each other as meaning one thing or another by our terms, and this ongoing practice is all that there is.

Kripke’s work generated enormous interest and a variety of responses in the literature. Some outraged students of Wittgenstein argued that it was not at all his intention to produce a paradox but to lay bare the oversimplifications, or desire for a simple theory, that trap people into finding rule following problematic (Baker and Hacker 1984). Many writers queried whether Wittgenstein could consistently have been content with a “non-truth-conditional” account of rule following, which is what Kripke offers him, since Wittgenstein’s abhorrence of theory and his belief that philosophy leaves everything as it is would make it impossible for him to say that it is not strictly speaking true that the application of words is correct or incorrect. Some (McDowell 1981)

detected a mischievous dislike of soft, humanly oriented facts in the setting up of the paradox and argued that a proper appreciation of the human constitution of rule following had wide implications for the notion of objectivity, as it occurs in domains such as aesthetics or ethics. Some (McGinn 1984) found that Kripke had not looked hard enough for natural facts with which to identify the obtaining of a rule; others (Blackburn 1985) embraced the thought that since the loss of a normative element in meaning was the main problem underlying the paradox, and since naturalistic theories of normativity have been proposed in many guises, a more generous sense of how to talk about facts solves the paradox. Paul Boghossian (1989) provided a summary of the state of the debate and a controversial contribution to it.

RULE FOLLOWING [ADDENDUM]

Paul Boghossian (1990) summarizes four components of what has become the received interpretation of Saul Kripke’s book *Wittgenstein on Rules and Private Language* (1982) (*WRPL*): (i) Kripke’s meaning-skeptic argues that meaning is normative and from descriptive facts one cannot derive normative claims, so descriptive facts cannot explain or reduce meaning; (ii) nonreductive accounts of meaning are not vulnerable to the meaning-skeptic’s argument; (iii) Kripke’s skeptical solution is a kind of nonfactualism about meaning; and (iv) Kripke’s arguments do not show that an isolated individual cannot follow rules. Contributions to the literature about

rule-following published after 1989 include criticisms of the meaning-skeptic's argument, investigations of the nature and coherence of nonfactualism about meaning, revisionary interpretations of *WRPL*, and interpretations of Wittgenstein that challenge Kripke's and others' understanding of rule-following.

Ruth Garrett Millikan (1990) argues that the normativity of meaning can be explained in terms of biological purposes shaped and sustained by natural selection. Philip Pettit (1990) argues that the normativity of meaning is explained by one's dispositions to question or revise a judgment when one has reason to think it was the result of interfering factors, such as poor lighting or intoxication. According to Paul Horwich (1995), there is a sense of "determine" in which facts about the use of a linguistic expression *E* can determine the meaning of *E*, even if the meaning of *E* cannot be "read-off" from those facts, as Kripke's meaning-skeptic argues.

Boghossian (1990) argues that nonfactualism about meaning is incoherent because it simultaneously *presupposes* and *conflicts with* deflationism about truth. Robert Kraut (1993) responds to this argument by describing a kind of deflationism about truth that seems compatible with nonfactualism about meaning. Crispin Wright (1992) and Scott Soames (1999) also identify what they regard as errors in Boghossian's argument.

George Wilson (1992) criticizes (iii), citing passages of *WRPL* that suggest that ascriptions of meaning can be factual even if they are not determined by independently specifiable facts. Against (i), José Zalabardo (1997) argues that the heart of the meaning-skeptic's argument is not that from descriptive facts one cannot derive normative claims, but that no facts of which we can be immediately aware can determine that our application of a word to a new case is justified. Gary Ebbs (1997) criticizes both (i) and (ii) by reconstructing Kripke's skeptical reasoning in a way that does not presuppose reductionism about meaning. Donald Davidson (1992) qualifies (iv) by supplementing Kripke's account of meaning-ascriptions with the premise that meaning requires triangulation.

Donna Summerfield (1990) reads Wittgenstein as presenting a positive account of representation that does not apply to an individual in isolation. Edward Minar (1991) presents an alternative to Kripke's skeptical solution and to the communitarian view that rule-following is constituted by linguistic interactions between speakers. David Bloor (1997) defends a communitarian interpretation of Wittgenstein. David Finkelstein (2000) suggests that to understand Wittgenstein one must come to see

that there is not always a gulf between a rule and its application.

RULE-UTILITARIANISM

See *Utilitarianism [addendum]*

RUSKIN, JOHN

(1819–1900)

John Ruskin, the English critic of art and society, was born in London, the son of a wine merchant. He began writing while at Oxford and in 1843 published, in London, the first volume of *Modern Painters*, four more volumes of which were published during the next sixteen years. In 1849 he published *The Seven Lamps of Architecture* and between 1851 and 1853 *The Stones of Venice* (3 vols.). The major part of his work as a young man was criticism of art and architecture, and his subsequent ethical and social writing grew from this root. The beginnings of this important extension of his range can be seen in the famous chapter “The Nature of Gothic” in *The Stones of Venice*; the important connection established there, between art and “the right kind of labour,” is developed in *The Political Economy of Art* (printed as *A Joy for Ever*, 1857), *Unto This Last* (1862), *The Crown of Wild Olive* (1866), and *Munera Pulveris* (1863 and 1872). Meanwhile Ruskin continued his criticism of art and architecture, notably in *The Two Paths* (1859) and in his lectures as Slade professor of art at Oxford, between 1870 and 1879 and in 1883/1884. A volume of essays, *Sesame and Lilies*, appeared in 1865 and an unfinished autobiography, *Praeterita*, between 1885 and 1889. He also published letters on social questions, notably in *Time and Tide* (1867) and *Fors Clavigera* (8 vols., 1871–1884).

Ruskin’s social and ethical teaching, though deeply influenced by the work of Thomas Carlyle, followed from his understanding of the nature of art. The artist’s function is to reveal aspects of the universal truth, which is also beauty. Any corruption of the moral nature of the artist is an inevitable corruption of this revelation, but it is impossible, finally, for an artist to be good if his society is corrupt. The art of any society is, correspondingly, “the exact exponent of its social and political virtues.” Where there is a lack of “wholeness” in art (wholeness being a full and deep response to the organic life of the universe), there is a corresponding lack of “wholeness” in society; to recover the one men must recover the other. Just as the beauty of art is the expression of the essential nature of the universe—what Ruskin called “typical beauty”—so the goodness of man is the “exertion of perfect life,” which, in comparable relation to the grand design of the created universe, is no more and no less than the “felicitous fulfillment of function” in all living things.

From his work on Venice, Ruskin developed a comparative historical approach to the social conditions in which the “exertion of perfect life” can be fostered or

damaged. In particular, following the English romantic writers and the architectural critic A. W. Pugin, he saw nineteenth-century industrial civilization as the enemy of wholeness in its rampant individualism, its substitution of “production” for “wealth,” and its basic misunderstanding of the nature of work. This kind of social criticism came in many respects to resemble the ideas of some philosophical socialists, and Ruskin’s work had an important formative influence on the British labor movement, both directly and through his influence on William Morris, who united Ruskin’s ideas with a direct commitment to socialism.

Ruskin’s opposition to individualism as a social principle and to competition as a method of political economy was based on his idea of function, the fulfillment of each man’s part in the general design of creation. This required a social order based on intrinsic human values, whereas the existing social order, based on the supposed laws of supply and demand, tended to put the economy above men—indeed, to reduce them to mere “labor”—and, by separating work from the pursuit of human perfection, to separate the work from the man, producing only an alienated and fragmented being. Wherever value is understood as “exchange value,” rather than as the “intrinsic value” derived from function in the universal design, this corruption of man to a mere tool or machine is inevitable. In particular, the confusion about the nature of value leads to false definitions of both wealth and labor. Labor is degraded whenever it is anything other than the “exertion of perfect life,” a creative activity comparable to that of the artist. Wealth is degraded whenever it is confused with mere production, for the meaning of wealth is human well-being, which in material terms is “the possession of useful articles *which we can use*.” Even if the existing system always produced useful articles, the kind of society that it also produced made just distribution and wise consumption impossible. Much actual production, and its widespread misuse, could more properly be called “illth” than “wealth,” for if it possessed only exchange value and not intrinsic value it corrupted its makers and its users.

The most remarkable aspect of Ruskin’s work, then, is the development of a philosophy of art into a moral critique of industrial capitalism. It is a very individual achievement, but it is also part of a general movement of nineteenth-century English thought and has evident connections with William Wordsworth, Percy Bysshe Shelley, Samuel Taylor Coleridge, and Carlyle, as well as with Morris and the Guild Socialists whom Ruskin so notably influenced.

RUSSELL, BERTRAND ARTHUR WILLIAM (1872–1970)

Bertrand Arthur William Russell, the British philosopher, mathematician, and social reformer, was born in Trelleck, Wales. He was the grandson of Lord John Russell, who introduced the Reform Bill of 1832 and later twice served as prime minister under Queen Victoria. John Stuart Mill, a close friend of Russell's parents, was his godfather in an informal sense. Russell's parents died when he was a little child. Both of them had been freethinkers, and his father's will had provided that he and his brother were to have as their guardians friends of his father's who shared the latter's unorthodox opinions. As the result of litigation the will was set aside by the Court of Chancery and the two boys were placed in the care of their paternal grandparents. Lord John Russell died two years later, and it was the boys' grandmother who determined the manner of their upbringing. Russell was not sent to school but received his early education from a number of Swiss and German governesses and, finally, English tutors. He entered Cambridge University in October 1890 and studied mathematics and philosophy at Trinity College from 1890 to 1894. He was a fellow of Trinity College from 1895 to 1901 and lecturer in philosophy there from 1910 to 1916. In 1916 Russell was dismissed by Trinity College

because of his pacifist activities. He was reinstated in 1919 but resigned before taking up his duties.

What is generally considered Russell's most important work in philosophy was done between 1900 and the outbreak of the first world war. From 1916 until the late 1930s Russell did not hold any academic position and supported himself by writing and public lecturing. During this period he wrote some of his most influential books on social questions, including *Marriage and Morals* (London, 1929) and his two books on education—*On Education, Especially in Early Childhood* (London, 1926) and *Education and the Social Order* (London, 1932). These views were put into practice in Russell's experimental school, the Beacon Hill School, which he started with his second wife, Dora, in 1927. Russell left the school in 1934 after he and Dora were divorced (the school itself continued until 1943). Russell returned to more concentrated work in philosophy around 1936. He moved to the United States in 1938, teaching first at the University of Chicago and then at the University of California at Los Angeles. In 1940 he accepted an invitation from the Board of Higher Education of New York City to join the department of philosophy at City College. However, he never had an opportunity to take up this appointment, having been found unfit for this position in a remarkable opinion by a judge who felt he had to protect "public health, safety and morals." From 1941 until 1943 Russell lectured at the Barnes Foundation in Philadelphia (these lectures were later expanded into *A History of Western Philosophy*). Dr. Albert Barnes, the head of this foundation, dismissed Russell in January 1943, on three days' notice. In this instance Russell successfully brought action for wrongful dismissal. In 1944 he returned to Cambridge where he had been reelected to a fellowship at Trinity College.

Russell was a candidate for Parliament on three occasions and was defeated each time: In 1907 he ran at Wimbledon as a candidate of the National Union of Women's Suffrage Societies, in 1922 and 1923 he stood as the Labour Party candidate for Chelsea. Russell was twice jailed—in 1918 for six months on a count of an allegedly libelous article in a pacifist journal and in 1961, at the age of eighty-nine, for one week, in connection with his campaign for nuclear disarmament.

In 1908 Russell was elected a fellow of the Royal Society. He became an honorary fellow of the British Academy in 1949, and in the same year he was awarded the Order of Merit. Russell twice served as president of the Aristotelian Society and was for many years president of the Rationalist Press Association. In 1950 he received the

Nobel Prize for literature. In making the award, the committee described him as “one of our time’s most brilliant spokesmen of rationality and humanity, and a fearless champion of free speech and free thought in the West.”

Russell had three children and was married four times. In 1931, upon the death of his brother, he became the third earl Russell.

Writing in 1935 the German historian Rudolf Metz referred to Russell as “the only British thinker of the age who enjoys world-wide repute.” At that time his works could not circulate in Germany, Italy, or Russia. Now they are available in every major and a great number of minor languages (a truncated version of *A History of Western Philosophy* was allowed to circulate even in the Soviet Union). It is safe to say that not since Voltaire has there been a philosopher with such an enormous audience. Russell also shares with Voltaire a glittering and graceful prose style and a delicious sense of humor. It is perhaps Russell’s humorous irreverence as much as the substance of his heretical opinions that has so deeply offended several generations of moralists and religious conservatives.

In the following section we shall briefly recount some of the highlights and formative influences in Russell’s eventful life and sketch his views on political and social issues. Although these views are certainly logically independent of his more technical work as a philosopher, they deal with questions that have traditionally been discussed by philosophers, and they also help one to understand the basic motives inspiring Russell’s thought.

LIFE AND SOCIAL THEORIES

Russell’s childhood and adolescence were unhappy. The atmosphere in his grandmother’s house was one of puritan piety and austerity, and his loneliness, he recalls, was almost unbearable. Only virtue was prized—“virtue at the expense of intellect, health, happiness, and every mundane good.” At the age of five Russell reflected that if he lived to be seventy, he had endured only a fourteenth part of his life, and he felt the long-spread-out boredom ahead of him to be unendurable. In adolescence, he remarks, he was continually on the verge of suicide, from which, however, he was “restrained by the desire to know more mathematics.” His grandmother had gradually moved from Scottish Presbyterianism to Unitarianism. As a child Russell was taken on alternate Sundays to the parish church and to the Presbyterian Church, while at home he was taught the tenets of Unitarianism. When he was fourteen he began to question theological doctrines and in the course of four years abandoned successively belief in free will, immortality, and God, the last as the

result of reading John Stuart Mill’s *Autobiography*. For some time, however, Russell had metaphysical attachments that served as substitutes for religion, and it was not until the end of the first world war that he became a militant opponent of all forms of supernaturalism.

EARLY PLATONISM AND HEGELIANISM. Under the influence of J. M. E. McTaggart and F. H. Bradley, Russell came, in his early years at Cambridge, to believe “more or less” in the Absolute and the rest of the apparatus of British Hegelianism. “There was a curious pleasure,” Russell wrote in retrospect, “in making oneself believe that time and space are unreal, that matter is an illusion, and that the world really consists of nothing but mind.” In a “rash moment,” however, he turned “from the disciples to the Master.” G. W. F. Hegel’s remarks in the philosophy of mathematics he found “both ignorant and stupid,” and in other ways Hegel’s work appeared a “farrago of confusions.” After that Russell was converted by G. E. Moore to a “watered down” version of Plato’s theory of Ideas, regarding the subject matter of mathematics as eternal and unchanging entities whose exactness and perfection is not duplicated anywhere in the world of material objects. Eventually Russell abandoned this “mathematical mysticism” as “nonsense.” Following Ludwig Wittgenstein he came to believe “very reluctantly” that mathematics consists of tautologies. As to the timelessness of mathematics, Russell now regarded this as resulting from nothing more than that the pure mathematician is not talking about time. Aside from this, it became emotionally difficult for him to remain attached to “a world of abstraction” in the midst of the slaughter of the Great War. “All the high-flown thoughts that I had had about the abstract world of ideas,” he wrote later, “seemed to me thin and rather trivial in view of the vast suffering that surrounded me.” The nonhuman world, he added, “remained as an occasional refuge, but not as a country in which to build one’s permanent habitation.” After his abandonment of Platonism, Russell wrote, he was not able to find religious satisfaction in any philosophical doctrine that he could accept.

PACIFISM. Russell was interested in social questions throughout his life. He was an early member of the Fabian Society and for some time in the 1890s, under the influence of Sidney and Beatrice Webb, championed imperialism and supported the Boer War. In 1901 he had a quasi-religious experience. He became “suddenly and vividly aware of the loneliness in which most people live” and felt the need to find ways of “diminishing this tragic isolation.” In the course of a few minutes he changed his

mind about the Boer War, about harshness in the education of children and in the administration of the criminal law, as well as about fierceness in personal relations. This experience led him to write his famous essay "A Free Man's Worship" (1903). Although Russell became a pacifist right then, for another ten years or more he was preoccupied with work in mathematical logic and theory of knowledge. It was not until the war that he became passionately concerned about social issues. It is probable, he observed later, that "I should have remained mainly academic and abstract but for the War." The war, however, "shook him" out of many prejudices and made him reexamine a number of fundamental questions. He recalled:

I had watched with growing anxiety the policies of all the European Great Powers in the years before 1914, and was quite unable to accept the superficial melodramatic explanations of the catastrophe which were promulgated by all the belligerent governments. The attitude of ordinary men and women during the first months amazed me, particularly the fact that they found a kind of pleasure in the excitement. (*Selected Papers of Bertrand Russell*, p. xi)

He decided that he had been quite mistaken in believing the claims of pacifists that wars were the work of devious tyrants who forced them on reluctant populations. Although he was not then familiar with the theories of psychoanalysis, Russell concluded that the majority of human beings in our culture were filled with destructive and perverse impulses and that no scheme for reform would achieve any substantial improvement in human affairs unless the psychological structure of the average person was suitably transformed.

Russell recalls that his decision to oppose the war was made particularly difficult by his passionate love of England. Nevertheless, he had no doubt as to what he had to do. "When the war came I felt as if I heard the voice of God. I knew that it was my business to protest, however futile protest might be. My whole nature was involved. As a lover of truth, the national propaganda of all the belligerent nations sickened me. As a lover of civilisation, the return to barbarism appalled me" (*Portraits from Memory*, p. 27). Russell remarks that he never believed much tangible good would come from opposition to the war, but he felt that "for the honor of human nature," those who "were not swept off their feet" should stand their ground. He patiently argued in lectures and books that the slaughter of millions of men was not justified by any of the possible gains of a defeat of the Central Powers. Russell's pacifism was not mystical. It was not then and

had not been his contention at any time that the use of force is always wrong, that war can never possibly be justified. He maintained that *this* war in *these* circumstances was not worth all the pain and misery, and the lying of all the parties. Consistently with his general position, Russell favored the Allies during World War II on the ground that the defeat of the Nazis was essential if human life was to remain tolerable. The Kaiser's Germany by contrast was "only swashbuckling and a little absurd," allowing a good deal of freedom and democracy.

Prior to the war there had been strong pacifist sentiment in all the major Western countries, especially among the intellectuals and the powerful socialist and liberal parties. When war came only a tiny minority of these pacifists remained true to its convictions. Overwhelmed by their need to conform and in many cases by what Russell would have regarded as their own primitive impulses, many of them became the most violent jingoists. Russell was bitterly attacked for his pacifist activities not only, as one might have expected, by conservatives and professional patriots but also by many of his erstwhile friends. H. G. Wells, for example, publicly heaped abuse on Russell when he was already in trouble with the authorities. Russell's political philosophy, according to Wells, amounted to a "tepid voluntarism," and he (unlike Wells) had no right to speak for British socialism. Wells even abused Russell's work as a mathematical philosopher. Russell, he wrote, is that "awe-inspiring" man who "objected to Euclid upon grounds no one could possibly understand, in books no one could possibly read" (preface to P. H. Loyson, *The Gods in the Battle*, London, 1917).

At Cambridge, Russell's teacher and friend McTaggart led a move for his ouster. Meetings addressed by Russell were broken up by violent mobs without any police interference. Eventually he was prosecuted by the government. For writing a pamphlet on the case of a conscientious objector he was fined £100. When he would not pay the fine the government sold parts of his library, including rare books on mathematics that Russell was never able to recover. In 1918 he was sentenced to six months' imprisonment for an article in the *Tribunal*, a pacifist weekly, in which he had written that "unless peace comes soon ... the American garrison, which will by that time be occupying England and France, ... will no doubt be capable of intimidating strikers, an occupation to which the American army is accustomed when at home." In a fierce denunciation which accompanied the sentence, the magistrate, Sir John Dickinson, referred to Russell's offense as "a very despicable one" and added that Russell "seems to

have lost all sense of decency.” It should be added that as the result of the intervention of Arthur Balfour, Russell was treated with consideration while in prison—he finished there his *Introduction to Mathematical Philosophy* and began work on *The Analysis of Mind*.

Attitude toward the Soviet Union. Russell’s isolation was not ended with the return of peace. This was due to his failure to support the Bolshevist regime in Russia. Like many Western socialists he at first welcomed the news of the revolution, but, wanting to see things for himself, he visited Russia in 1920 and came back totally disillusioned. Some of Russell’s friends argued that any criticism of the revolution would only play into the hands of the reactionaries who wanted to reestablish the old order. After some hesitation Russell decided to publish the truth as he saw it. Russia, he later wrote, “seemed to me one vast prison in which the jailors were cruel bigots. When I found my friends applauding these men as liberators and regarding the regime that they were creating as a paradise, I wondered in a bewildered manner whether it was my friends or I that were mad.”

The little book in which he recorded his views of the Soviet Union, *The Theory and Practise of Bolshevism* (1920), was remarkable for, among other things, its prescience. Long before most Westerners had heard of Joseph Stalin, Russell predicted, point by point, the reactionary features that came to characterize the Soviet system under Stalin—its militarism and nationalism, the hostility to free art and science, its puritanism, and the gradual ascendancy of bureaucrats and sycophants over the early idealists. Russell was able to reprint the book in 1947 without a single alteration. His isolation after his return from Russia was even greater than during the war. The patriots had not yet forgiven him his opposition to the war, while the majority of his former political friends denounced him for his opposition to the Soviet regime. But Russell has never played to the galleries. As on many other occasions he acted in accordance with his favorite biblical text—“Thou shalt not follow a multitude to do evil.”

Education and sexual morality. Probably the most controversial of Russell’s opinions are those relating to education and sexual morality. These were closely connected with his observations of the joy people took in the fighting and killing during the war. Russell wrote that he thought he saw the inward and outward defeats that led to cruelty and admiration of violence and that these defeats were, in turn, largely the outcome of what had happened to people when they were very young. A peaceful and happy world could not be achieved without dras-

tic changes in education. In sexual matters, although not only in these, irrational prohibitions and dishonesty were exceedingly harmful. “I believe,” he wrote in *Marriage and Morals*, “that nine out of ten who have had a conventional upbringing in their early years have become in some degree incapable of a decent and sane attitude towards marriage and sex generally” (p. 249). Conventional education was judged to be at fault in a great many other ways as well. Its general tendency was to cramp creative impulses and to discourage a spirit of critical inquiry. While a certain amount of discipline is necessary, very much of the coercion traditionally employed cannot be justified. The child who is coerced “tends to respond with hatred, and if, as is usual, he is not able to give free vent to his hatred, it festers inwardly, and may sink into the unconscious with all sorts of strange consequences throughout the rest of life.”

Although puritanical moralists were or professed to be violently shocked by Russell’s views on sex and education, it is worth emphasizing that his recommendations are not extreme and that unlike his opponents he stated his position temperately and without recourse to personal abuse. Russell may be characterized as a “libertarian” in education, but he was strongly opposed to the view of other educational pioneers who played down the importance of intellectual training and encouraged originality without insisting on the acquisition of technical skill. Similarly, although he may quite fairly be called a champion of free love, it is grossly misleading to describe Russell as an advocate of “wild living.” On the contrary, he disavowed any such intentions. He wrote:

The morality which I should advocate does not consist simply in saying to grown-up people or adolescents: “follow your impulses and do as you like.” There has to be consistency in life; there has to be continuous effort directed to ends that are not immediately beneficial and not at every moment attractive; there has to be consideration for others; and there should be certain standards of rectitude. (*Marriage and Morals*, p. 243)

But this does not mean that we should be “dominated by fears which modern discoveries have made irrational.” Russell could see nothing wrong in sexual relations before marriage, and he advocated temporary, childless marriages for most university students. This, he wrote, “would afford a solution to the sexual urge neither restless nor surreptitious, neither mercenary nor casual, and of such a nature that it need not take up time which ought to be given to work” (*Education in the Modern*

World, pp. 119–120). It would be wrong to regard Russell as an enemy of the institution of marriage. He did indeed object to keeping a marriage going when no love is left, and, what shocked people a great deal, he remarked that a “permanent marriage” need not exclude “temporary episodes,” but he also emphatically affirmed that “marriage is the best and most important relation that can exist between two human beings ... something more serious than the pleasure of two people in each other’s company” (*Marriage and Morals*, p. 115).

Russell’s views on sexual morality featured prominently in the New York City case of 1940. When his appointment was announced, Bishop Manning of the Episcopal Church wrote an inflammatory letter to all New York City newspapers in which he denounced Russell’s subjectivism in ethics and his position on religion and morality. It was unthinkable that “a man who is a recognized propagandist against both religion and morality, and who specifically defends adultery” should be held up “before our youth as a responsible teacher of philosophy.” The bishop’s letter was the beginning of a campaign of vilification and intimidation unsurpassed in a democratic nation in recent times. The ecclesiastical journals, the Hearst press, and numerous Democratic politicians joined in the chorus of abuse. Russell was described as “the Devil’s minister to men,” as an advocate of “the nationalization of women,” as “the mastermind of free love and of hatred for parents,” and also, needless to say, as an exponent of communism.

The climax of the campaign was a taxpayer’s suit by a Mrs. Jean Kay of Brooklyn demanding that Russell’s appointment be annulled. The case was heard before Justice McGeehan, who had previously shown his notions of tolerance by trying to have a portrait of Martin Luther removed from a courthouse mural illustrating legal history. In a startling decision, which was bitterly criticized by legal experts as in many respects grossly improper, McGeehan voided Russell’s appointment on three grounds: First, Russell had not been given a competitive examination; second, he was an alien and there was no reason to suppose that the post in question could not be competently filled by an American citizen; and, finally, the appointment would establish “a chair of indecency.” Elaborate arguments were adduced in behalf of this last claim. Among other things it was maintained that Russell’s doctrines would tend to bring his students “and in some cases their parents and guardians in conflict with the Penal Law.” In some fashion not explained by the judge, Russell’s appointment would lead to “abduction” and rape. Russell’s opposition to the laws that make

homosexuality a crime was misread as advocacy of a “damnable felony ... which warrants imprisonment for not more than 20 years in New York State.” Evasive actions of the mayor of New York, Fiorello La Guardia, prevented any effective appeal against this monstrous decision, and Russell was never able to take up his position at City College. In 1950, shortly after receiving the Nobel Prize, he returned to New York to deliver the Machette Lectures at Columbia University. He received a rousing reception that those who were present were not likely to forget. It was compared with the acclaim given Voltaire in 1784 on his return to Paris, the place where he had been imprisoned and from which he had later been banished. As for McGeehan, it is safe to say that he will go down in history as a minor inquisitor who used his one brief moment in the limelight to besmirch and injure a great and honest man.

McGeehan did not pass judgment on Russell’s competence as a philosopher, but other opponents of the appointment were not so restrained. Thus, Joseph Goldstein, attorney for Mrs. Kay, described Russell as “lecherous, libidinous, lustful, venerous, erotomaniac, aphrodisiac, irreverent, narrow-minded, untruthful, and bereft of moral fiber.” After a few gratuitous lies about Russell’s private life, he concluded:

He is not a philosopher in the accepted meaning of the word; not a lover of wisdom; not a searcher after wisdom; not an explorer of that universal science which aims at the explanation of all phenomena of the universe by ultimate causes ... all his alleged doctrines which he calls philosophy are just cheap, tawdry, worn-out, patched-up fetishes and propositions, devised for the purpose of misleading the people.

In the present encyclopedia a somewhat different view is taken of the value of Russell’s philosophy. Some of his most important theories in epistemology and metaphysics will be discussed in the next section, his contributions to logic and the foundations of mathematics will be covered in the following section, and his views on ethics and religion will be dealt with in the last section. However, a number of Russell’s most interesting ideas are not at all or only briefly discussed in the present entry. Many of these are treated elsewhere in the encyclopedia.

EPISTEMOLOGY AND METAPHYSICS

Russell exercised an influence on the course of Anglo American philosophy in the twentieth century second to that of no other individual. Yet, unlike many influential thinkers, he neither founded nor attached himself to any

definite movement. Although he wanted above all to be empirical, he always had reservations of one sort or another to the proposition that all acceptable beliefs can be derived from purely empirical premises, and although his stress on analysis as the proper philosophical method is one of the chief sources of the analytical bent that philosophy currently has in English-speaking countries, he never accepted the view that philosophy is nothing but analysis.

EARLY REALISM. Russell's first distinctive philosophical work was colored by a violent reaction against the absolute idealism then dominant in England, which was ultimately based on the thought of G. W. F. Hegel and whose outstanding British exponent was F. H. Bradley. According to Bradley if we try to think through the implications of any fact whatever, we will inevitably be forced to conclude that everything that there is constitutes a single, immediate unity of consciousness. In Russell's view the main weapon used to bludgeon people into submission to this result was the "doctrine of internal relations," according to which any relational fact—for example, that x is above y —is really a fact about the natures of the terms involved. This doctrine in effect refuses to take relations as ultimate.

It follows from this position that whenever x and y are related, each "enters into the nature of the other." For when x is above y , then being above y is part of the nature of x and being below x is part of the nature of y . Hence, y is part of the nature of x and x is part of the nature of y . Since everything is related to everything else in one way or another, it follows that everything else enters into the nature of any given thing, which is just another way of saying that there is no "other thing" relative to a given thing. In other words, the only thing that exists is one all-comprehensive entity. From the related principle that when we are aware of something, that something enters into the nature of the awareness or of the mind which has the awareness, it follows that it is impossible to conceive of anything which is not included within consciousness. Thus, the one all-comprehensive entity is a unity of consciousness.

Although in his youth Russell, with most of his philosophical contemporaries, was caught up in this philosophy, he and G. E. Moore became disenchanted with it shortly before the turn of the twentieth century. Russell came to hold that in sense perception we are as immediately aware of the relations between things as of the things themselves and therefore that any philosophy which denied ultimate reality to relations must be mis-

taken. Moreover, he came to think that mathematics would be impossible if we held that every relation enters into the nature of its terms; for in mathematics we must understand what our units are before we can know anything about their relations to other units. Russell therefore argued for a "doctrine of external relations," according to which relations have a reality over and above the terms they relate and do not enter into the definition of the terms they relate. This led him to a kind of philosophical atomism that thenceforth was characteristic of his philosophy. We may think of the basic core of atomism, which runs through all the shifts in Russell's later philosophizing, as being constituted by the following principles:

(1) There are nonmental facts that are what they are whether or not any mind ever becomes aware of them. This does not follow from the doctrine of external relations, but that doctrine enabled Russell to reject the idealistic argument based on the doctrine of internal relations and thus left him free to hold his native realist convictions with a good conscience.

(2) A particular proposition (for example, that my car is in the garage) can be unqualifiedly true "in isolation." This follows from the thesis that facts are "atomic" in the sense that any given fact could hold, whatever is the case with the rest of the world, together with the correspondence theory of truth—that what makes a true proposition true is its correspondence with an objective fact. Hegelians, on the other hand, had argued that since one could not adequately think about any particular fact without inflating it into the absolute totality of being, whenever one is saying something short of everything, what he is saying is not quite true in any absolute sense.

(3) An important corollary of (2) is the usefulness of analysis as a method in philosophy. If it is possible to get an adequate grasp of the parts of a totality without considering their place in the whole, then it is possible to give an illuminating account of something complex by showing how its simple parts are related to form the whole. Hegelians had argued that analysis cannot get started because we cannot understand what any part is without already seeing how it fits into the whole, which means already knowing everything about the whole. The conviction that analysis is the proper method of philosophy has remained the most prominent strand in Russell's thought.

Intoxicated by his release from idealism, Russell, as he later put it, tended to accept as objectively real anything that the absolute idealists had not succeeded in showing to be unreal. Numbers, points of space, general

properties like roundness, physical objects as they appear to sense perception, were all regarded as having an independent existence. Under the influence of Alexius Meinong this extreme realism was reinforced by an extreme form of the referential theory of meaning, the view that in order for a linguistic expression to have a meaning there must be something that it means, something to which it refers. In this stage of Russell's thought, represented most fully by *The Principles of Mathematics* and to a lesser extent by *The Problems of Philosophy*, Russell was inclined to think that the meaningfulness of the sentence "The car is in the garage" required that there be objectively existing referents not only for the words *car*, *garage*, and *in* but even for the words *the* and *is*. An objectively existing "isness" soon proved to be too much for Russell's self-proclaimed "robust sense of reality." He came to think that terms belonging to the logical framework of sentences, such as "the," "is," "or," could perform their function without each being correlated with extralinguistic referents. Nevertheless, a modified form of the referential theory of meaning continued to dominate Russell's thinking.

LOGICAL CONSTRUCTIONISM. Russell's decisive shift away from the full-blooded realism of *The Principles of Mathematics* came with the development of logical constructionism. The theory can be generally stated as follows. We start with a body of knowledge or supposed knowledge which we feel strongly inclined to accept but which has the following drawbacks: (1) the knowledge claims do not seem to be adequately justified, (2) there are unresolved problems about the natures of the entities involved, and (3) we feel uncomfortable about committing ourselves to the existence of such entities. If we can show that this body of knowledge could be formulated in terms of relations between simpler, more intelligible, more undeniable entities and that when so formulated there is a decisive justification for it, we will have made a philosophical advance. We will have converted the problematic to the unproblematic, the obscure to the clear, the uncertain to the certain. Russell called this technique logical constructionism because the problematic entities were said, in a possibly misleading metaphor, to be "constructed" out of the simpler ones.

Reduction of mathematics to logic. The technique of logical constructionism was first employed in the theory of mathematics worked out by Russell and A. N. Whitehead and published in *Principia Mathematica* (3 vols., 1910–1913). In the *Principia* the authors set out to show that all of pure mathematics can be stated in terms of logic, using no undefined terms other than those required

for logic in general—for example, implication, disjunction, class membership, and class inclusion. In the course of carrying out this reduction, various more or less problematic mathematical entities were "constructed" out of what were thought to be less problematic entities. Thus, numbers were defined as classes of classes: Zero is the class of all empty classes. The number 1 is the class of all classes each of which is such that any member is identical with any other member. The number 2 is the class of all classes each of which is such that it includes a member not identical with another member and such that any member is identical with one or the other of these. If one is puzzled about what sort of entity a number is (it does not seem to be in space or time and is not perceivable by the senses) or is uncomfortable about assuming that such queer entities exist, he will presumably be reassured by the discovery that he can think of numbers as classes of classes of familiar, unproblematic entities. Of course analogous problems may arise with respect to the entities made use of in this first reduction—for example, classes. And in fact various difficulties in doing mathematics in terms of classes led Russell to try to "construct" classes out of "prepositional functions." (See the section on logic and mathematics, below.) Starting from a given point we may well have to perform a series of reductions before we get down to maximally intelligible, indubitable entities.

Construction of physical objects. After *Principia Mathematica*, Russell applied the technique of logical constructionism to our knowledge of physical objects, both in physical science and in common sense. Physical theories are formulated in terms of a variety of unperceivable entities—electromagnetic fields, protons, energy quanta, forces exerted at a point, and so on. There are serious problems in the philosophy of science both about the content of our concepts of such entities and about the basis for our accepting their existence. We can try to show that such entities can be inferred from what we know about perceivable entities, but how could we get an empirical basis for a principle correlating observed and unobserved entities? Or we can try to show that unobserved entities have to be postulated in order to give an adequate explanation of observed happenings, but it seems impossible to show conclusively that no adequate explanation could be given purely in terms of observables. If we apply the constructionist principle, "Whenever possible, substitute constructions out of known entities for inferences to unknown entities," to this problem, we shall try to show that electromagnetic fields can be construed as complexes of less problematic entities related in various ways. Russell devoted a large proportion of his philosophical energy to trying to show that sci-

entific entities can be constructed out of undeniable data of perception. But it will be easier to illustrate this kind of analysis by taking ordinary physical objects like trees and buildings, for Russell thought that they raise analogous problems, although in less obvious ways.

There is a long tradition, dominant since the time of René Descartes, according to which common sense is mistaken in supposing that we directly perceive physical objects. According to this tradition what we are directly and indubitably aware of in sense perception is something private to the individual observer. There are several sources of this view, the most important of which are, first, the fact that the content of one's perception can change with, for example, changes in perspective, lighting, and physiological condition of the observer, without there being any change in the physical object which, according to common sense, one is perceiving, and, second, the fact that in dreams and hallucinations one can have experiences which are intrinsically indistinguishable from those one has when one is "really" seeing a tree, but in these cases no tree is present. In dreams and hallucinations one is really aware of something that is not a physical object and is not perceivable by anyone else. And since these experiences are intrinsically just like those in which a physical object is present, one must be perceiving these private objects in the latter cases as well. This consideration is reinforced by the first, which is designed to show that even where a physical object admittedly is involved, I am often aware of different things without the physical object's undergoing any change.

The conclusion of these arguments is that the colors, shapes, sounds, and so on, of which we are directly aware in sense perception (sense data) are private objects that must be distinguished from the entities in the physical world (if any) which we suppose ourselves to be perceiving. This conclusion inevitably gives rise to the question how, if at all, I can start from the private objects of whose existence I can be certain and show that public, physical objects like trees exist. No generally accepted solution to this problem has emerged in several centuries of discussion. Here again Russell tries to avoid the necessity for an inference by showing that the public physical objects can be construed as a complex structure of data of immediate experience. At first Russell aimed at a solipsistic reduction in which a given physical object would be constructed out of the actually experienced data of a single observer, but he soon came to lower his aspiration and to admit into the construction data experienced by others, as well as data which would have been experienced by others if they had been in a certain place. The view, then, is that a tree

can be regarded as a system of all the actual and possible sense experiences that would be regarded as figuring in perceptions of that tree. This is a form of the position known as phenomenalism, and it is subject to the difficulties to which that position is notoriously subject, particularly the apparent impossibility of specifying which experiences go into defining a particular physical object without referring to that physical object or others in the specification.

Construction of mind. Until about 1920 Russell was a mind-matter dualist. As we have just seen, physical objects were regarded as complex structures of data of the sort given in sense perception. Now, although the mind might be partly constituted by data which are given to "inner sense"—that is, things which are the objects of introspective awareness, such as images and feelings—it seemed to Russell, as it had to most philosophers, that in any act of awareness, be it directed to the external or to the internal world, there is in addition to the data of which one is aware a subject or self which has the experience or which performs the act of awareness. But as the spirit of logical constructionism took increasing hold of Russell, he came to feel that there was no real warrant for believing in a subject of awareness which performs acts. He became convinced that one cannot really find any such constituent of the experience; its apparent obviousness is a reflection of the grammar of the sentences in which we speak about such matters—we say "I saw a flash of light" rather than "A flash of light occurred." As it presents itself, a minimal piece of consciousness does not involve a relation between two components. It is a unitary whole. Only the flash of light is given. The "I" and the "saw" are added interpretations. If we have no real basis for accepting a subject or mind as an ultimate entity, then the logical constructionist will try to show that it can be exhibited as a complex of entities of which we are directly assured by our experience. Here Russell followed the lead of William James, who had earlier formulated a view known as neutral monism, according to which both mind and matter consisted of the data of immediate experience, the difference between them lying in the grouping of the constituents.

Thus, if I am looking at a tree the visual datum (an irregularly shaped green splotch) of which I am directly aware is both part of my mind and part of the tree. When grouped together with other experiences from this and other perspectives that would be said to be experiences of that tree, it goes to make up a tree; when grouped with other data bound together in a single conscious field, along with other data related to these by memory, it goes

to make up a mind. If this theory is acceptable, traditional puzzles about the mind-body relation are dissolved. We are faced not with two radically distinct kinds of stuff but with two different kinds of arrangement of the same elementary components. (That is, some of the components are the same. Russell considers images to be peculiar to mind.) It is in the light of this theory that one should consider Russell's notorious view that what one perceives is always his own brain. Whenever I have any sense perception whatever, I do so because a certain kind of physical activity is going on in my brain. This activity, as a physical process, is to be regarded, like all physical processes, as a construction out of the sort of data given in immediate experience. And since whatever may be the case otherwise, my brain is always active when I perceive, the data of which I am aware enter into the constitution of my brain, whatever other entities they may enter into. Hence the paradoxical view that whenever one is conscious he is aware of his own brain.

When Russell abandoned the subject of experience as an ultimate constituent of the world he rejected sense data and thenceforth spoke simply of sense experiences. But he would have represented his view more clearly by saying that he had given up belief in anything other than sense data. For in the old paradigm of *subject aware of sense data*, it was the subject exercising awareness that was abandoned. In *The Analysis of Mind* Russell set out to construct the conscious mind out of sensations and images. (Insofar as facts regarded as mental do not consist of consciousness, Russell's strategy is to give a behavioristic analysis. Thus, desire, belief, and emotions can be regarded as made up, at least in part, of dispositions to behave in one way rather than another in certain circumstances.) The results are admittedly equivocal. Russell has always been too honest to overlook glaring deficiencies in his analyses. One that has particularly bothered Russell is this: On a commonsense basis it seems clear that one must distinguish between simply having a sensation and taking that sensation as an indication of a tree, and there seems to be an important difference between simply having an image and employing that image in, for example, thinking about a forthcoming election. If this analysis of mind is to be made to work, one must give an account of the reference of perception and thought in terms of the interrelations of data. Thus, we might hold that to take a sensation as an indication of a tree is to be disposed to have the sensation of surprise if certain other sensations were to follow. But apart from difficulties about the nature of these dispositions, which are themselves neither images nor sensations, this is all extremely difficult to

work out in detail, and it is equally difficult to make sure that one has shown that it can be done.

It is clear that logical constructionism is based on a tendency opposite to that of the realism briefly espoused by Russell in his youth. Logical constructionism wields Ockham's razor with a heavy hand. We begin with those entities whose existence is indubitable because they are given in immediate experience, and we then try to show that anything we might wish to say about anything else can be stated in terms of relations between these indubitable entities. In other words, anything we want to say about something else is not really about something else. Thus, we try to represent all our knowledge as having to do with as few kinds of entities as possible, thereby reducing the possibility of error.

LOGICAL ATOMISM. Thus far we have concentrated on the epistemological side of logical constructionism, its concern with reducing the number of assumptions we make and with exhibiting clearly the basis for what we claim to know. But it also has a metaphysical side, although Russell wavers about this. Sometimes he talks as if his constructionism is metaphysically neutral. At such times he says that in showing that minds can be constructed out of sensations and images we do not show that there is no ultimate, irreducible subject of awareness; we show merely that everything we know about minds can be expressed without assuming the existence of such an entity. At other times, however, he claims that by showing that minds can be constructed out of sensations and images we have shown what minds really are—we have revealed their metaphysical status. And by carrying through constructions of everything that can be constructed out of simpler entities we will have developed a complete metaphysical scheme.

Ideal language. The most systematic presentation of this metaphysical side of logical constructionism is found in the set of lectures *The Philosophy of Logical Atomism*, which Russell gave in 1918. Here Russell makes explicit the principle on which a metaphysical interpretation of logical constructionism depends—namely, isomorphism of the structure of an ideal language and of the structure of reality. If we can determine in outline how the world would be described in an ideal language, we will have, in outline, an account of what the world is like. The restriction to an "ideal" language is essential. Since there are alternative ways of stating the same body of facts, it could not be the case that all these ways reflect the real structure of the world. In this approach to metaphysics the basic metaphysical commitment is to the identity of structure

between reality and an ideal language, and one shows one's hand metaphysically by choosing one rather than another set of criteria for an ideal language.

For Russell the most important requirement for an ideal language is an empiricist one, formulated in the "principle of acquaintance": "Every proposition which we can understand must be composed wholly of constituents with which we are acquainted." In other words, we can understand a linguistic expression only if it either refers to something we have experienced or is defined by other expressions which are so used. This principle plays a part in the constructions we have been surveying, as do the considerations we have already made explicit. That is, Russell holds not only that if physical objects were not defined in terms of sense experiences we would have no way of *knowing* anything about them but also—and even more important—we would not be able to *understand* talk about them. In logical atomism this principle is reflected in the requirement that the expressions which figure in the "atomic" sentences in terms of which everything is to be expressed must get their meaning through direct correlation with experience. They will, therefore, be names of particular sense data and terms for properties of sense data and relations between sense data. Russell is forced to exclude the logical framework of sentences from this requirement ("is," "the," etc.), but he is recurrently uneasy about this exclusion and recurrently disturbed by the question how, in that case, we can understand them.

In addition to the need for its undefined terms getting their meaning through correlation with immediately experienced items, the ideal language will have to satisfy some more strictly logical requirements. These will include the absence of vagueness and having one and only one expression for each meaning. But the most important restriction concerns the form of the basic sentences. An atomic sentence will be one that contains a single predicate or relational term and one or more than one name, the whole sentence asserting that the entity named has the indicated property ("This is white") or that the entities named stand in the indicated relation ("This is above that"). If a sentence (1) has this form, (2) contains only terms that get their meaning through correlation with experienced items, and (3) has to do with entities that cannot be analyzed into anything simpler, then it is an atomic sentence. It is clear that for Russell the sentences which satisfy these requirements will all state a minimal fact about a momentary content of sense experience.

Logical atomism can then be presented as the thesis that all knowledge can be stated in terms of atomic sen-

tences and their truth-functional compounds. A truth-functional compound of two sentences is one whose truth or falsity is a determinate function of the truth or falsity of the components. Thus, "I am leaving and you are staying" is a truth-functional compound of "I am leaving" and "You are staying." For the compound is true if and only if both its components are true. There is an empiricist motivation for maintaining this thesis. Atomic sentences, in the sense specified above, can be conclusively verified or falsified by a single experience, and as long as we are dealing only with truth-functional compounds of these no further problem can arise concerning their truth or falsity. Consider a "contrary-to-fact conditional," such as "If I had offered him more money, he would have accepted the job." As it stands this sentence is not a truth-functional compound of its constituents. For in saying it we are presupposing that both its constituents are false, yet this does not settle the question whether the whole statement is true or false. There is a corresponding puzzle about what empirical evidence would settle the question. Obviously I cannot go back in time and offer him more money and see what he will do. If we could find some way to restate this as a (very complicated) truth-functional compound of atomic sentences, it would become clear which experiences would verify or falsify it.

Pluralism and knowledge by acquaintance. The metaphysical correlate of this sketch of the ideal language brings together two of Russell's deepest convictions, the logical independence of particular facts (pluralism) and the dependence of knowledge on the data of immediate experience. In this view reality consists of a plurality of facts, each of which is the sort of fact which could be infallibly discerned in a single moment of experience and each of which could conceivably be what it is even if nothing else were in existence. All the familiar and seemingly relatively simple objects in the world of common sense are really extremely complicated complexes of atomic facts of these sorts.

Russell was well aware that logical atomism in this extreme form was untenable. For example, he insisted that generalizations could not be truth-functional compounds of atomic sentences. The most promising way of so construing them would be to take, for example, "All lemons are yellow" as a conjunction of a large number of atomic sentences of the form "This lemon is yellow," "That lemon is yellow," But as Russell points out, even if it were possible to list *all* the lemons, the conjunction would say the same thing as the original universal generalization only if we added the conjunct "and that is all the lemons there are." And this last addition is not an atomic

sentence. Moreover, Russell had doubts about so-called intensional contexts, such as “Smith believes that the White Sox will win,” where the truth or falsity of the compound is clearly independent of the truth or falsity of the components. Whether Smith has this belief does not in any way depend on whether the White Sox win. Russell has always hoped that neutral monism would help him to get out of this difficulty. If we could construct beliefs out of sensations and images we might be able to restate this fact as some truth-functional derivative of atomic sentences.

Later doubts. In the mid-twentieth century Russell came to have more fundamental doubts about logical atomism, including doubts concerning the very notion of a logical atom. How can we ever be sure that we are dealing with something that cannot be further analyzed into parts? How can one be sure that yellowness is an absolutely simple property? More basically, what makes a property *logically* simple? Does the fact that one can explain the word *yellow* to someone by saying “Something is yellow if it has the same color as the walls of your room” show that being the same color as the walls of your room is logically a *part* of yellowness? If so, then yellowness is not absolutely simple. If not, what does count against logical simplicity? Moreover, if there are alternative minimum vocabularies, then a simple, undefined term in one mode of formulation may turn out to be definable in another. Thus, on one systematization “pleasure” might be defined as the satisfaction of desire, whereas on a different systematization “desire” would be defined as the belief that something is pleasant. Russell gave up the belief that we can know that we have gotten down to ultimate simples and even the belief that there must be absolute simples. He became disposed to think, in more relativistic terms, of a class of things that can be taken as simple at a given stage of analysis. In those terms he still tended to fall back on sense experiences that are as apparently simple as anything we can find. Such experiences, even if not absolutely simple, can be regarded as being independent of anything except their possible components.

LATER DEVELOPMENTS. Despite Russell’s frank admissions that logical atomism does not work as a depiction of the structure of an ideally adequate language, he did not develop an alternative metaphysics. On the principle of isomorphism, if one cannot represent general statements as functions of atomic statements, then one must admit general facts as ultimate constituents of the world. This metaphysical implication did not seem to bother Russell as it once had. This is partly because he became less pre-

occupied with metaphysics in his later years and partly because the principle of isomorphism became so heavily qualified as to remove most of the cutting edge. In his major philosophical works of the 1940s, *An Inquiry Into Meaning and Truth* and *Human Knowledge*, he is more concerned with the nature of atomic facts thought of as the ultimate pieces of empirical data and the kinds of inferences required to get from these to the rest of what one wants to count as knowledge than he is with inferring a metaphysical structure from the logical form which an adequate statement of our knowledge would assume.

In these works there is a major shift in his view of the structure of atomic facts. Russell had earlier interpreted the word *this* in “This is red” as referring to a particular, something which has qualities and stands in relations but is not itself a quality or relation or set of qualities or relations. This is the traditional concept of substance as the substratum of properties, which was still alive in the realm of sense data even after physical objects and minds were no longer taken to be substances. But eventually the sense datum as substratum of properties went the way of physical objects, minds, and numbers. Here, too, Russell became convinced that there is no empirical warrant for assuming the existence of any such thing. In sense experience I am aware of a variety of qualities and their interrelations, but I am not also aware of something which *has* qualities. The bearer of qualities turns out to be the shadow of the usual grammatical form of the sentences used to report atomic facts. (There is a subject of the sentence—for example, “this”—which does not refer to any quality.) Russell’s latest position was that the subject of qualities is simply a construction out of a set of compresent qualities. Thus, in the ideal language “This is red” would be restated as “Red is compresent with ...,” where in place of the dots we have a specification of the other properties involved in that experience, for example, being round, being in the middle of the visual field, having ragged edges. It might be thought that this necessarily involves giving up the idea of absolute simples, for what takes the place of things in this view is bundles of qualities. But in this theory qualities themselves are regarded as the ultimate particulars (possibly simple) of which the world consists. Thus, in “Red is compresent with ...” “red” does not refer to a particular exemplification of redness. If we took that line we would have to suppose that there is something which distinguishes *this* exemplification from other exemplifications of just the same color, and that would have to be something as unempirical as a substratum. Instead, it is taken to refer to the color conceived as a “scattered particular,” something which can

exist in a number of different places at the same time. And such a particular might well be simple.

Russell continued to think of commonsense physical objects and the entities of physics as constructions out of entities of the sort that are given in sense experience. But he came to require less similarity to sense data in the elements of these constructions. His later view was that although all ultimate entities have basic structural similarities to sense experiences, they need not involve only qualities that are given in sense experience. They may have qualities that it is impossible for us to be aware of. This uncertainty does not carry with it any serious gap in our knowledge, since for physical science it is the structure of external events that is important. In the 1940s Russell became increasingly concerned with the principles that are required to justify inferences from sense experience to unexperienced events and complexes of unexperienced events. The simplest form this takes is, for example, the inference that my desk has continued to exist in my office throughout the night, when no one was observing it. On Russell's view this is an inference from certain sense experiences to structurally similar events spatiotemporally connected with them in certain ways. He felt that the principle of induction by simple enumeration (the more often one has observed *A* and *B* to be associated, the more it is likely that they are invariably correlated) is insufficient to justify such inferences. What is needed, he thought, is a set of assumptions having to do with spatiotemporal connections of events of like structures. In *Human Knowledge* he presents a set of such assumptions. He does not claim that they can be *known* to be true. His point is a Kantian one: We must accept these assumptions if we are to accept the inferences to unobserved events that we all do accept in the course of our daily life.

Russell's entire philosophical career was dominated by the quest for certainty. In the middle decades of the twentieth century he was driven to admit that it is less attainable than he had hoped, but nevertheless the desire to approximate it as much as possible continued to shape his thinking about knowledge and the nature of the world. Because of this desire he was continually preoccupied with the problem of how to formulate those pieces of knowledge that are rendered indubitable by experience. And because of it he consistently attempted to analyze anything that appears dubitable into constituents about which there can be no doubt. Even where he was forced to admit that inferences beyond the immediately given are inevitable, he strove to reduce the principles of such inferences to the minimum. Russell is distinguished

from other seekers after absolute certainty chiefly by the ingenuity of his constructions and by the candor with which he admits the failures of the quest.

LOGIC AND MATHEMATICS

REDUCTION OF MATHEMATICS TO LOGIC. Russell's main work in logic and mathematics was concerned with the problem of bringing the two together and with the interpretation of mathematics—arithmetic in particular—as a simple extension of logic, involving no undefined ideas and no unproved propositions except purely logical ones. Russell achieved this synthesis at the beginning of the twentieth century, a little later than Gottlob Frege, but independently of him; in working it out in detail he had the collaboration of A. N. Whitehead. By current standards Russell's work lacks rigor, and in this respect it compares unfavorably with that of Frege; at an early stage, however, Russell did notice a difficulty that had escaped Frege's attention, the paradox about the self-membership of classes, which will be examined later. Because of its complexity it will be best to treat Russell's picture of the logical foundations of mathematics systematically rather than historically, with occasional comments about the actual development of his thought. We shall also separate from the outset two elements of Russell's treatment of his and other paradoxes, the theory of "types" and the theory of "orders," which Russell himself ran together, and thereby give a slightly clearer picture of his intention than his own writings immediately furnish.

Definition of "similarity." Russell took over from Giuseppe Peano the reduction of all other arithmetical notions to complications of the three arithmetically undefined ideas of "zero," "number," and "successor" and defined these in terms of the theory of logical relations between classes or sets. In particular, he defined a number as a class of classes with the same number of members; for example, he defined the number 2 as the class of pairs. This procedure may seem unnatural (do we really mean by "2" the class of two-membered classes?) and circular. To the charge of unnaturalness Russell's answer was that his definition (together with the definitions of addition, etc.) gives all the ordinary results ($2 + 2 = 4$, for example) and that for a pure mathematician this is enough; another answer can be given only after it has been made clearer what Russell means by a class. With regard to the charge of circularity, Russell defines the complex "having the same number of members," or "similarity," as he calls it, not in terms of "number" (or of his definition of "number") but in other terms altogether.

At this point some notions from the logic of relations have to be introduced. A relation is said to be one to one if whatever has that relation to anything has it to one thing only and if whatever has anything standing in that relation to it has one thing only standing in that relation to it. (In strictly monogamous countries, “husband of” is a one-to-one relation in this sense.) Here the phrase “one only” does not presuppose the notion of the number 1. The sentence “ x stands in the relation R to one thing only” means “For some y , whatever x stands in the relation R to is identical with y .” The domain of a relation is the set of objects that stand in that relation to anything (the domain of “husband of” is the class of all husbands); the relation’s converse domain is the set of all objects to which anything stands in that relation (the converse domain of “husband of” is the class of individuals that have husbands—that is, the class of wives). A class A is similar to (that is, has the same number of members as) another class if there is some one-to-one relation of which the first class is the domain and the second the converse domain.

One can see that in a monogamous country the class of husbands will be similar in this sense to the class of wives, but one might think that two sets of objects could have the same number of members without there being any relation at all that pairs them off in the way that “husband of” does in our example. This, however, is a mistake when the term *relation* is understood as widely as it is by Russell. A relation in Russell’s sense is, roughly, anything that can be expressed by a sentence with two gaps in it where names might go, and this covers not only obvious relating expressions like “_____ shaves ()” or “_____ is the husband of ()” but also ones like “Either _____ is identical with A , or B is identical with ().” Take any set of two objects C and D . The relation “Either _____ is identical with A and () with C , or _____ is identical with B and () with D ” (where all dashes must be replaced by the same name, and similarly with the bracketed blanks) will be a one-to-one relation in which A stands to C alone and B to D alone and in which C has A alone standing to it and D has B alone—that is, it will be a one-to-one relation of which the class with A and B as sole members is the domain and the class with C and D as sole members the converse domain; there are analogous relations in the case of larger classes. (Where the classes are infinitely large these relations will not be expressible in a language with only finite expressions, and perhaps that means that they will not be expressible in any language. Some philosophers would regard this as a serious difficulty; others would not.)

Axiom of infinity. Similarity, then, or having-the-same-number-of-members, is defined in terms of notions from the logic of relations: one to one, domain, and converse domain. The number-of-members of a given class is the class of classes similar to it, and a class of classes is a number (strictly, a cardinal number) if there is some class of which it is the number-of-members. This last step gives rise to another difficulty: Suppose there are (as there might well be) no more than a certain number n of objects in the universe. Then there will be no classes with more than n members and so, by the above definition, no cardinal numbers greater than n . This makes a great part of arithmetic (for example, the principle that every number has a successor different from itself) subject to the hypothesis (sometimes called the axiom of infinity) that there are an infinite number of objects.

Russell came to accept this last consequence of his definitions, but at an earlier stage he had thought that the axiom of infinity was provable, as follows: If we assume that every property demarcates a class, we must admit that some classes are empty (have no members), for example, there are no objects not identical with themselves. (The number 0 is precisely the class of classes with no members.) Thus, even if the universe contains no ordinary objects at all, there will still be at least one object of a more abstract sort, the universe itself considered as an empty class. And if there is this object there will also be two further objects of a still more abstract sort: the class of classes that has the first empty class as its one member and the empty class of classes. That makes three objects, call them A , B , and C . In addition to these there will be four classes of classes of classes—the class with B as its sole member, that with C as its sole member, that containing both B and C as members, and the empty class of classes of classes. And so on ad infinitum.

Russell paradox and the theory of types. Russell was led to abandon the above demonstration (which, as he said, has anyway “an air of hocus-pocus about it”) by his discovery of the paradox of self-membership, mentioned earlier. If we can concoct classes with some members that are themselves classes, some that are classes of classes, and so on as we please (if, in other words, we can treat classes, classes of classes, etc., as so many sorts of classifiable “objects”), we can, it seems, argue as follows: The most obvious classes do not contain themselves as members—for example, the class of men is not itself a man and so is not itself a member of the class of men (that is, of itself). On the other hand, the class of non-men *is* a non-man (is one of the things that are not men) and thus *is* a member of itself. We can therefore divide classes into two broad

classes of classes—the class of classes that are members of themselves and the class of classes that are not. Now take the class of classes that are not members of themselves: Is it a member of itself or not? If it is, it must possess the defining property of this class to which ex hypothesi it belongs—that is, it must be not-a-member-of-itself. (Thus, if it is a member of itself, it is not a member of itself.) And if it is not a member of itself, ipso facto it possesses its own defining property and so *is* a member of itself. (If it is not, it is.) Let p be the proposition that our class is a member of itself; it follows even from the attempt to deny it, so it *must* be true—but it entails its own denial, so it *must* be false. There is clearly something wrong here.

Russell thought the error lay in treating a class seriously as an object. Perhaps it is an object in a sense, but not in the same sense in which genuine individuals are objects—and classes of classes are different again. They are, as he put it, of different “logical type.” In particular, in an intelligible sentence you cannot replace an individual name by a class name or a class name by the name of a class of classes, or vice versa, and still have the sentence make sense. If “Russell is dead” makes sense, “The class of men is dead” does not, and if “The class of men is three-membered” makes sense (even if false), “Russell is three-membered” does not. And where a sentence makes no sense (as opposed to being merely false), its denial makes no sense either. Since “The individual I is a member of the class-of-individuals C ” makes sense, “The class-of-individuals C is a member of the class-of-individuals C ” does not and neither does “The class-of-individuals C is not a member of the class-of-individuals C ”—and so on at higher points in the hierarchy. This being granted, the paradox with which we began simply cannot be intelligibly formulated and thus disappears from the system.

At this point it would be wise to remove a possible source of confusion. The relation of class membership is different from the relation of class inclusion. One class is included in another if all the members of the former are members of the latter; for example, the class of men is included in the class of animals—all men are animals. But the class of men is not a member of the class of animals; that is, the class of men is not an animal (or, more strictly, “The class of men is an animal” is nonsense). The class of men is a member, rather, of the class of classes-of-animals—it is a class of animals. And the class of classes of animals is included in (but is not a member of) the class of classes of living things—any class of animals, in other words, is a class of living things. Inclusion thus relates classes of the same logical type; membership, on the other

hand, relates an entity with another entity of the logical type one above its own. The membership of an individual in a class of individuals is membership in a sense different from the membership of a class of individuals in a class of classes, and similarly for inclusion—there is a hierarchy not only of classes but also of membership and inclusion relations.

All this, besides solving a technical problem, is not without some attraction for philosophical common sense. Even apart from paradoxes it seems an artificial “multiplication of entities” to suppose that in addition to the individual objects which form the members of the lowest type of classes there are classes, classes of classes, and so on, and Russell devoted some attention to the problem of showing how what appears to be talk about these rather strange objects is in reality just more and more oblique talk about quite ordinary ones. To see just how he shows this it is necessary to look more closely at what might be called his “straight” language, into which this talk of classes, etc., does not enter and into which, once this talk *has* been introduced, it can always be “translated back.”

LOGIC. From what has been said so far, it is clear that the “logic” to which Russell reduced arithmetic covered, implicitly or explicitly, such subjects as class membership and class inclusion, identity, and some sort of theory of relations. This is that part of logic that we first encounter when we work back to logic from arithmetic. We must now try and work forward to the same point from the fundamentals of logic.

Russell thought of logic as being at bottom “the theory of implication” (to quote the title of one of his early papers). And from the first he considered it important to distinguish implication from inference. He objected to the view that logic is primarily about thinking—conception, judgment, and inference, as some of the traditional logic texts put it. The connection of logic with inference is rather that logic is concerned with that in the real world that makes inference justified, and this is implication. “Where we validly infer one proposition from another,” he wrote in 1903, “we do so in virtue of a relation which holds between the two propositions whether we perceive it or not: the mind, in fact, is as purely receptive in inference as common sense supposes it to be in perception of sensible objects” (*Principles of Mathematics*, p. 33).

Material implication. Even in Russell’s purely objective, nonpsychological sense “implication” is ambiguous. Implication may be a relation between complete propositions, in which case it is called “material” implication and

holds whenever it is not the case that the implying proposition is true and the implied proposition false. Before enlarging and commenting upon this account, certain grammatical and metaphysical clarifications are in order. Russell originally believed that sentences symbolized abstract objects called “propositions” and that material implication was a relation between these objects in exactly the same sense that marriage might be a relation between two people. He later dropped this view and regarded propositions, like classes, as mere “logical constructions,” but he still used the old forms of words (as being, no doubt, accurate enough for practical purposes). In particular, the partly symbolic form “ p implies q ” (or “ p materially implies q ”) freely occurs in all his writings, and we ought to be clear about what he means by it. Generally it is simply a variant of “If p then q ,” or completely symbolically “ $p \supset q$ ” (“ p hook q ”), where the phrase “If _____ then ()”—or the hook—is not a transitive verb expressing a relation between objects but a conjunction, or, as we now say, a “sentential connective.” “If p then q ” is thus not a statement about two objects symbolized by “ p ” and “ q ” but rather a complex statement about whatever the statements represented by “ p ” and “ q ” are about. For example, “If James is going to come, John will stay away” is not about two objects symbolized by “James is going to come” and “John will stay away,” nor is it about these subordinate sentences themselves; rather, it links these two sentences to make a more complex statement about James and John. And if we say “That James is going to come implies that John will stay away,” this is just a verbal variant of “If James is going to come then John will stay away”; that is, the linking expression “That _____ implies that ()” has the same meaning as the conjunction “If _____ then ().” The general form “That p implies that q ” thus has the same sense as the form “If p then q ” or “ $p \supset q$,” and Russell’s “ p implies q ” is thus just a loose way of saying “That p implies that q .” In a similar way Russell often uses “ p is true” and “ p is false” as variants of “It is the case (is true) that p ” and “It is not the case (is false) that p ”; although sometimes he may really be talking about sentences in such a way that the sentence “John will stay away” may be described as true if and only if John will stay away and as false if and only if he will not, and the sentence “James is going to come” may be said to “imply” the sentence “John will stay away” if and only if the sentence “If James is going to come then John will stay away” is true.

The assertion that an implication is true if and only if it is not the case that the implying statement (antecedent) is true and the implied statement (consequent) false is not intended as a definition of the form “If

p then q .” It is simply an informal attempt to fix our attention on the relation (or quasi relation) that Russell intends. In his earliest works, like Frege and C. S. Peirce before him, Russell took this relation to be undefinable, and “the discussion of undefinables—which forms the chief part of philosophical logic—is the endeavour to see clearly, and to make others see clearly, the entities concerned, in order that the mind may have that kind of acquaintance with them which it has with redness or the taste of a pineapple” (*Principles of Mathematics*, 1st ed., preface; 2nd ed., p. xv). Later he preferred to take as undefined the conjunction “or” and the negative prefix “it is not the case that” (or just “not”) and to define “If p then q ” as an abbreviation of “Either not p or q ”; later still he followed H. M. Sheffer and Jean Nicod in using the stroke form “ $p | q$ ” (which is true if and only if the component statements are not both true) and defined “if,” “not,” and “or” in terms of it. But for Russell the central part of logic has always been the study of implication, whether taken as undefined or not.

Since the form “If p then q ” as understood by Russell is true as long as it is not the case that the antecedent is true and the consequent false, it is automatically true if the antecedent is false (for then it is not the case that the antecedent is true and thus not the case that the-antecedent-is-true-and-the-consequent-false) or the consequent true (for then it is not the case that the consequent is false and thus not the case that the-antecedent-is-true-and-the-consequent-false). In other words, a false proposition materially implies, and a true one is materially implied by, any proposition whatever. But implication is supposed by Russell to justify inference, and the mere fact that “Grass is pink” is false would not seem to justify us in inferring the 25th proposition of Euclid from it, and the mere fact that Euclid’s proposition is true would not seem to justify us in inferring it from “Grass is green”—geometry would be much easier if we could do this. Russell’s explanation is that the first of these inferences cannot be performed because we cannot get it started (the premise not being true) and that the second inference is justified but we cannot know it to be so unless we already know the conclusion, so that we will not need it. In other words, “Infer a true proposition from anything at all” is a rule with no practical use, but this does not make it logically wrong.

Formal implication and propositional functions.

Implications are of practical use when we know their truth without knowing either the falsehood of their antecedents or the truth of their consequents, and this happens most often when a material implication is an

instance or particularization of an implication in the second of Russell's senses, a "formal" implication.

Formal implication is not (to use Russell's "realistic" language) a relation between propositions but one between what he calls "propositional functions." One might say roughly that formal implication is a relation between properties and that one property formally implies another if it is never present without the other; for example, being human formally implies being mortal (nothing is human without being mortal). Formal implication is clearly involved in the notion of class inclusion— A is included in B if being a member of A formally implies being a member of B . But the notion of a propositional function is wider than that of a property. It is what is meant by an "open sentence," a sentence in which some expression—say, a name—has been replaced by a variable. "Socrates is a man" expresses a proposition; " x is a man" expresses a propositional function. Sometimes, more simply, Russell uses the term *propositional function* for the open sentence itself. And the proposition that Socrates is a man may be said to be the *value* of the propositional function " x is a man" for the value "Socrates" of the argument x . The propositional function " x is a man" formally implies " x is mortal" if x 's being a man materially implies that x is mortal whatever x may be—that is, if we have "For any x , if x is a man then x is mortal." Russell writes this sort of implication as " $\phi x \supset \psi x$." At one stage he treated this notion, for systematic purposes, as undefined, but even then he regarded it as complex in meaning, being built up from material implication together with the prefix "for any x ," called a quantifier. Writing this last as " (x) ," we may spell out the sense of a formal implication by writing it as " $(x) : \phi x \supset \psi x$." It should be noted that whereas a propositional function is not a proposition, a formal implication between such functions is a proposition. The propositional function " x is a man" is neither true nor false; only its various values are true or false. But "For any x , if x is human then x is mortal" is as it were complete and is as it happens true. The quantifier is said here to "bind" the variable x , or, in the terminology Russell took over from Peano, x is in this context not a "real" but an "apparent" variable.

A propositional function may also have more than one expression in a proposition replaced by a variable, as in " x shaves y ," " x gives y to z ," and "If x shaves y then x does not shave z ." In such cases the function corresponds to a relation (two-termed or many-termed) rather than to a property, and such functions may again be linked by formal implication, as in "For any x and y , if x is a child of y then x detests y "—that is, "All children detest their par-

ents." Symbolically, we have here the form " $\phi xy \supset_{x,y} \psi xy$," or " $(x,y) : \phi xy \supset \psi xy$." Again, formal implication may link a propositional function and a complete proposition, as in "If anything is in that box I'm very much mistaken," which is of the form "For any x , if ϕx then p " or " $\phi x \supset_x p$." Moreover, the expression whose place is taken in a propositional function by a variable need not be a name. It might, for example, be a sentence—"If p then q " is a propositional function of which "If James is going to be there then John will not come" is the value when "James is going to be there" is the value of the argument p and "John will not come" the value of the argument q . If we prefix quantifiers to forms of this sort we obtain further formal implications, including the laws of propositional logic themselves—for example, "For any p , q , and r , if p implies q then if q implies r , p implies r ," which may be written " $(p,q,r) : (p \supset q) \supset ((q \supset r) \supset (p \supset r))$ " or " $(p \supset q) \supset_{p,q,r} ((q \supset r) \supset (p \supset r))$."

A further case of special interest is that in which a variable replaces a verb or equivalent expression, as in " ϕ (Socrates)," where ϕ stands indifferently for "is a man," "smokes," "is running," etc. With appropriate quantifiers this function will yield such formal implications as " $(\phi) : \phi a \supset \phi b$," " $\phi a \supset_{\phi} \phi b$ " (roughly, "Whatever a does, b does," or "Whatever goes for a goes for b "). However, Russell says not that " ϕ (Socrates)" and "If ϕ (Socrates) then ϕ (Plato)" are functions of the verb or predicate ϕ but that they are functions of the *function* ϕx or, as he writes it in this type of context, the function $\phi \hat{x}$ (the significance of this accenting or "capping" will be indicated later). His aim here is in part to bring out what Peirce and Frege called the "unsaturatedness" of verbs: The function of verbs can be understood only in relation to names and sentences; we use verbs to *make statements* about objects, not to name a special sort of object. The additional associated variables also enable one to represent unambiguously such complexes as "shaving oneself"—if ϕ is "shaves," shaving oneself is $\phi \hat{x} \hat{x}$, as opposed to simply shaving ($\phi \hat{x} \hat{y}$). But Russell was hampered by not having the word *functor* to designate what makes a function out of its argument; it is more natural to speak of "Socrates is a man" as a propositional function of "Socrates," of " x is a man" as the same propositional function of " x ," and of "is a man" as the functor which forms this function in both cases than to speak of " \hat{x} is a man" as a propositional function and to treat it in practice as a functor (Frege and W. E. Johnson were more accurate here, although they, too, lacked the term *functor*).

This part of Russell's "philosophical grammar" can now be set out fairly straightforwardly: Sentences may be

built out of other units in various ways—out of other sentences by connectives, as in “ $p \supset q$ ” and out of names by verbs, as in “ ϕx ,” “ ϕxy ,” and “ $\phi x \supset \psi x$ ” (which may be conceived of as constructed out of the subsentences “ ϕx ” and “ ψx ” by the connective “ \supset ” or out of the name “ x ” by the complex verb “ $\phi x \supset \psi x$,” “ ψ ’s-if-it- ϕ ’s”). The rest of the hierarchy goes on from here—there are, for example, functors that form sentences out of verbs (that is, out of functors that form sentences out of names) and functors that form sentences out of these again, and so on ad infinitum. Functors may require one or more than one argument to make a sentence (the difference between “is a man” and “shaves,” in the transitive sense), and when more arguments than one are required they may or may not be of the same type (for example, “If x is a man then p ” requires a name and sentence).

Quantification. Of functors that form sentences from verbs, the most important are quantifications, such as “ $(x)\phi x$ ” (which makes a sentence out of the verb whose place in the sentence is kept by “ ϕ ”), represented in English by such words as “everything,” “Everything” is, or is constructed out of, the universal quantifier; there are many other quantifiers. Russell distinguished one other basic quantifier, “something.” “Something is a man” expands in his language to “For some x , x is a man,” or symbolically $(\exists x)(x \text{ is a man})$.

Given the quantifier “something” and negation we can construct the complex “It is not the case that (for some x (x is a man))” or “For no x is x a man.” Here we have the philosophical beginnings of the number series. The number 0 makes its appearance as part of a quantification, for we could write the preceding form as $(0x)(x \text{ is a man})$. And the series can be continued. “Some” means “At least one, and “At most one thing is a man” is “For some, x , if anything is human it is identical with x ”—that is, “For some x : for any y , if y is human y is identical with x .” The combination of “At least one thing is a man” with “At most one thing is a man” gives us “Exactly one thing is a man” that is, “ $(1x)(x \text{ is a man})$.” “ $(2x)(x \text{ is a man})$ ” is, similarly, “At least two things are men, and at most two things are men”—that is, “(For some x and for some y , x is a man, y is a man, and y is not identical with x) and (for some x and for some y : for any z , if z is a man z is either identical with x or identical with y).” Apparent occurrences of numbers as objects can be analyzed away in terms of this primary sense; “1 and 1 is 2” for instance, becomes “For any ϕ and for any ψ , if exactly one thing ϕ ’s, exactly one thing ψ ’s, and nothing does both, then exactly two things either- ϕ -or- ψ .” Numbers are inseparable components of functors of functors of names, or, as Russell

would say, functions of functions, but the naturalness of this analysis is disguised in his own work by the fact that before he brings arithmetic into the picture he introduces the language of classes and defines numbers in terms of classes. (The notation “ $(0x)\phi x$,” etc., is not Russell’s.)

DESCRIPTIONS. Before going on to Russell’s discussion of classes, we should note that “ $(x)\phi x$,” “ $(\exists x)\phi x$,” and also “ $(0x)\phi x$,” “ $(2x)\phi x$,” and so on, are *functions* of functions of names, not *arguments* of such functions—that is, they are not names. “Something,” “nothing,” “exactly one thing,” etc., are not names, although, like names, they go with verbs to make sentences. They go, so to speak, on the other side of verbs: They “govern” the verbs; the verbs do not govern them. And although Russell’s hierarchy of types of functors or “functions” provides innumerable ways of constructing sentences (and so of constructing functions), it provides no way of constructing genuine names. It is of the essence of the expressions represented by Russell’s variables of lowest type (x , y , z , etc.)—that is, individual names—that they are logically structureless; they pick out individuals, and that is all. But in common speech and in mathematics we do seem to construct names, or at least ways of designating objects, out of expressions of other types: For example, “the man who broke the bank at Monte Carlo” seems to function as a name, yet it seems to be constructed from the verb “broke the bank at Monte Carlo.” On Russell’s view this appearance is illusory, and sentences in which such apparent names occur can always be replaced by paraphrases expressed entirely in Russell’s language of structureless names, functions of functions, etc. However, he regarded it as useful for logical symbolism to reproduce at this point, although with greater precision, some of the devices of common speech and to have, as it were, a secondary language imposed on the primary one.

(Some account of Russell’s handling of descriptions—that is, expressions of the form “The so-and-so”—and of other points raised below is given in the entry Existence.) “There ϕ -er,” or “The thing that ϕ ’s,” when it occurs as the apparent subject of a further verb—that is, in a context of the form “The ϕ -er ψ ’s”—is in reality a functor, in some way like a quantifying expression, of which the verbs “ ϕ ’s” and “ ψ ’s” are arguments; in fact “The thing that ϕ ’s ψ ’s” amounts precisely to “Exactly one thing ϕ ’s, and whatever ϕ ’s ψ ’s,” whose first component has been analyzed above and whose second component is a simple formal implication. Expressions of this kind are especially important in mathematics when the contained functor ϕ is relational in form, as in “The ϕ -er of y ”—that is, “The thing that ϕ ’s y ,” “The square root of y ” (the num-

ber that yields y when multiplied by itself) is such an expression. Russell called expressions of this kind “descriptive Functions.” They include most “functions” in the ordinary mathematical sense. It is a little inaccurate, of course, to use name symbols like “ y ” for numbers, which on Russell’s view are not genuine individuals, but once the devices that yield class language and number language have been worked out, Russell’s analysis of descriptive functions can be reproduced at the new level in a transposed form. This language of classes and numbers, to which we shall now turn, is itself a case of a secondary language containing apparent names (like “The class of persons that shave themselves”) that disappear from the primary-language paraphrase.

CLASSES, FUNCTIONS, AND PROPERTIES. Russell represented the form “The class of things that φ ” as “ $\hat{x}(\varphi x)$ ”—usually read as “the x ’s such that φx —and represented “ y is a member of the class of φ -ers” as “ $y \in \hat{x}(\varphi x)$.” Alternatively we may read “ $\hat{x}(\varphi x)$ ” simply as “ φ -er” and “ $y \in \hat{x}(\varphi x)$ ” as “ y is a φ -er.” The expression “ y is a φ -er” is true if and only if $y \varphi$ ’s. One can in fact simply define “ $y \in \hat{x}(\varphi x)$ ” as “ φy .” Given this definition, other concepts associated with class theory are easily introduced. For example, as noted earlier, “The class of φ -ers is included in the class of ψ -ers” amounts to the formal implication “For any x , if x is a φ -er then x is a ψ -er.”

Classes of classes are related to functions of functions as classes are related to functions. To say that a given class— $\hat{x}(\varphi x)$, for example—is a member of the class of two-membered classes (or, as Russell would write it, “ $\hat{x}(\varphi x) \in 2$ ”) is just to say that exactly two things φ —i.e., the class of classes that Russell identifies with the number 2 is just the correlate in the class hierarchy of the function of functions $(2x)\hat{\varphi}x$.

Counting classes. There are two difficulties in Russell’s views concerning classes. One is that classes, and, for that matter, numbers, can themselves be counted, as can individuals, but a number of classes would have to be not a class of classes but a class of classes of classes, and a number of numbers would similarly have to be a class of classes of classes of classes. This means that when we say “The number of numbers between 2 and 5 is 2,” the first “2” has a sense quite different (belongs to a place quite different in the type hierarchy) from the second; and this seems a little implausible. Russell at this point is content to speak of the “systematic ambiguity” of the key expressions of his symbolic language. Given the proof of “ $1 + 1 = 2$,” for instance, considered as a statement about numbers of individuals, an analogous proof can always be

constructed for the analogous statements about numbers of classes, numbers of numbers, etc., so that in practice it does not matter at which place in the type hierarchy we are working, provided we keep the types going up in order.

Ludwik Borkowski has suggested what may be a better solution: Suppose we always express quantification by a sign followed by a variable; for Russell’s “ (x) ” we might put “ $(\forall x)$,” by analogy with “ $(\exists x)$.” We might then use the term *quantifier* not for this expression as a whole but for the initial sign, which can then be described as a functor that constructs a sentence out of a variable followed by a sentence, usually an “open” sentence in which the variable just mentioned occurs. We might then say that the initial sign “ \forall ” or “ \exists ”—or in the case of numerical quantifiers “0” or “1” or “2,” etc.—is of the same logical type whatever the type of the variable that comes between it and the sentence following it. For counting properties (and, therefore, classes), we would have prefixes like “ (2φ) ”—for example, “ $(2\varphi)\varphi(\text{Socrates})$ ” would mean “Socrates has exactly two properties” or, better, “Exactly two things are true of Socrates”; and “ (2φ) ” is different from “ $(2x)$,” but the “2” is exactly the same in both contexts.

Counting functions. The other difficulty in Russell’s theory is that classes dissolve into functions, but we do not count classes and functions in quite the same way. We would say, for example, that any two-membered class has four subclasses, in the sense that there are four ways of selecting members from such a class (both members, the first only, the second only, and neither). The corresponding theorem about functions would seem to be this: If exactly two things φ , then for exactly four ψ ’s, whatever ψ ’s φ ’s. But in fact there will always be vastly more than four ψ meeting this condition. Suppose, for example, that there are just two men in a room—i.e., $(2x)(x \text{ is a man in the room})$ —and that one of them wears spectacles, spats, spotted socks, a red tie, and striped trousers; this much alone gives us five ψ ’s (namely, “_____ is a man in the room wearing spectacles,” “_____ is a man in the room wearing spats,” etc.), such that whatever ψ ’s is a man in the room. The key point here is simply that we count classes as being the same when they have the same members, but we do not count propositional functions as being the same merely because they are satisfied by the same arguments, and all the numerical concepts that are built up from the concept of identity must be similarly adjusted. For instance: “At most one class is a sub-class of $\hat{x}(\varphi x)$ ” does not mean “For some ψ : for any χ , if $\hat{x}(\chi x)$ is a subclass of $\hat{x}(\varphi x)$, then χ -ing is the same as ψ -ing,” but rather it means “For some ψ : for any χ , if $\hat{x}(\chi x)$ is a sub-

class of $\hat{x}(\varphi x)$, then whatever χ 's ψ 's and whatever ψ 's χ 's." It is the same when we move up a type and count numbers themselves. If we write " $(0x)(\varphi x)$ " for "It is not the case that (for some x , φx)" and " $(0'x)(\varphi x)$ " for "For any x , if $x \varphi s$ then x is not identical with itself," we may say that these are different functions of functions—but whatever function either of them applies to the other applies to also; thus, they determine a single class of classes and a single "number," 0. The class and number language that Russell superimposes on his basic one is such that this is the way these quasi entities are counted.

Extensionality. One very radical way of simplifying this whole problem (one that Russell has considered from time to time) is to say that functions (properties, relations, etc.) are to be counted in just the same way that classes are; that is, that if $\varphi \hat{x}$ and $\psi \hat{x}$ characterize precisely the same objects (are formally equivalent), they are the same function. This is called the principle or law of extensionality; it in effect simply identifies a function with its "extension"—that is, with the class that it determines. The objection to this principle is simply its extreme implausibility in particular cases. For example, it seems obvious that even when two individuals and these two only are the men in a certain room wearing spats and the men in that room wearing spectacles, being a man in the room with spats is something different from being a man in it with spectacles.

Quine's criticism. Logicians such as W. V. Quine, following Ernst Zermelo and John von Neumann, have developed systems in which classes, classes of classes, and so on, are treated not as logical constructions but as genuine objects, and Russell's paradox is dealt with not by saying that " x is (is not) a member of x " is meaningless but by denying that " $x\varphi$'s" always implies that x is a member of the class of φ -ers. This account runs into difficulty when we try to handle certain nonmathematical properties of these supposed objects. Russell's view seems to have the advantage of not unnecessarily "multiplying entities," but Quine argues that Russell succeeds in dispensing with classes only by making genuine objects of properties or functions. This is said on the ground that in the course of his treatment of classes and numbers Russell is compelled to quantify over predicate variables—that is, to employ such quantifiers as " $(\exists \varphi)$ " (for example, in defining "Exactly as many things ψ as χ as "For some relation, φ whatever φ 's anything ψ 's and vice versa, whatever is φ 'd by anything χ 's and vice versa, and whatever φ 's or is φ 'd by anything φ 's or is φ 'd that thing only"). This, Quine says, is to make properties and relations (like

φ -ing) the "values of bound variables," and to do this is to treat them as existing.

This amounts to saying that to generalize an expression by quantifying over it is ipso facto to make it a name of an object; but this claim may be contested. We do not elucidate "He must have killed him somehow" by translating it "There must be some way in which he killed him" (which, taken literally, suggests that there are objects called "ways") but rather vice versa: We understand "somehow" directly as a generalization of qualifications like "with a knife," and the "way" line of talk is merely a variant of this. Even "something" is often to be understood as a generalized adjective rather than as a generalized individual name—for example, when I say "I am something that Jones is not—logical." It seems more plausible to interpret "I have something that Jones has not—logicality" as a verbal variant of the preceding sentence than to say that the latter alone brings out what I am really doing. And the logical rules for such higher-order quantifications are simple—we proceed from the specific case to the generalization, from "I am logical and Jones is not" to "For some A , I am A and Jones is not A ," exactly as we do from "I am logical but not intelligent" to "For some individual x , x is logical but not intelligent."

Elimination of abstract terms. Russell might more plausibly be said to "hypostatize" or "reify" abstractions on the ground that there are some contexts from which it seems impossible to eliminate from his basic language his symbols for "abstracts," that is, φx , etc. This part of his system is developed more tidily in Alonzo Church's calculus of λ -conversion, in which the property of φ -ing is represented not by " $\varphi \hat{x}$ " but by " $\lambda x \varphi x$," and of " ψ -ing if one φ 's" by " $\lambda x . \varphi x \supset \psi x$." The basic rule of this calculus is that the application of $\lambda x \varphi x$ to an object a , symbolized by $(\lambda x \varphi x)a$, is equivalent to the plain φa , and similarly $(\lambda x . \varphi x \supset \psi x)a$ is equivalent to $\varphi a \supset \psi a$. And where we have a function of functions f , we can in general similarly replace $f(\lambda x \varphi x)$ by $f(\varphi)$ —but not always. For instance, it is an obvious law that any such function f which holds for any φ whatever will hold for χ -ing-if-one- ψ 's, as in formula F :

$$(f) : (\varphi) f(\varphi) . \supset . f(\lambda x . \psi x \supset \chi x).$$

Here the expression with λ seems uneliminable. We cannot replace it with " $\psi \supset \chi$," for this is meaningless—the hook joins sentence forms, not predicate forms. Where we have a specific f the elimination is again possible; for example, if f is the function "applying to exactly two objects," then $f(\lambda x . \psi x \supset \chi x)$ will amount to $(2y) : (\lambda x . \psi x \supset \chi x)y$ and thus to $(2y)(\psi y \supset \chi y)$. But where the f

itself is a variable, as it is in formula F , nothing of this sort is done. We could indeed (following Stanisław Leśniewski) introduce a symbol for the predicate “ χ -ing-if-one- ϕ ’s” by a special definition; for example

$$[\supset \psi \chi]x =_{\text{Df}} \phi x \supset \psi x$$

and so replace F with G :

$$(f) : (\phi)f(\phi) . \supset .f([\supset \psi \chi]),$$

but then it would be impossible to eliminate the defined symbol from G in favor of the symbols by which it is defined, and it seems an odd sort of definition that would be thus limited. (Church’s use of λ can in fact be regarded as simply a generalization of Leśniewski’s procedure.)

The uneliminability of “abstracts” from these contexts is an odd and perhaps awkward fact, but it need not be taken to imply that there are abstract objects, for “abstracts” need not be regarded as a kind of name. In expositions of the λ -calculus it is often said that the form $\lambda x \phi x$ corresponds to the ordinary-language quasi noun “ ϕ -ing,” but this is not strictly correct, as may be seen from the fundamental equation $(\lambda x \phi x)a = \phi$ If “ ϕ ” here represents not a name but a verb (“ ϕa ” means “ a ϕ ’s”), then so must “ $\lambda x \phi x$ ” (“ $(\lambda x \phi x)a$ ” also means “ a ϕ ’s”), so that if f in $f(\phi)$ is a function with not names but predicates as arguments, so it must be in “ $f(\lambda x \phi x)$.”

RAMIFIED THEORY OF TYPES. We may now describe the added feature that makes Russell’s own presentation of his theory of types more complex than the presentation so far given here. Russell divides functions into types not only according to the types of argument that they take but also according to whether they do or do not involve an internal reference to all functions of (what appear to be) their own type. For example, the function \hat{x} has all the qualities of a great general” has individual-name arguments, just as “ \hat{x} is brave” does, but unlike “ \hat{x} is brave” it has a “for all ϕ ” within itself—it amounts to “For all ϕ , if whoever is a great general ϕ ’s, then \hat{x} ϕ ’s.” Russell therefore regards it as of a different type, or, as he often says, of a different order, from “ \hat{x} is brave.” Functions that do not thus involve a reference to all functions of (what appear to be) their own type he calls “predicative” functions and symbolizes them by putting an exclamation mark or “shriek” after the symbol, as in “ $\phi!x$.” Functions cannot in fact (on Russell’s view) strictly contain references to all functions of *their own* type or order but references only to ones of orders below their own. A function of individuals, which contains a reference to all predicative functions of individuals, is not itself predica-

tive and cannot be regarded as being among the functions to which it implicitly refers. Having all the properties of a great general, for example, is not itself a property of a great general, at least not in the same sense of “property”—it is a second-order property.

What this means in practice might be illustrated as follows: It seems that if there were no facts about x —that is, if for no ϕ , ϕx —then there would be at least one fact about x , namely the fact that there are no facts about it, and hence it cannot be that there are no facts about x . In symbols, from

$$(1) \quad \psi x \supset (\exists \phi)(\phi x)$$

it seems possible to obtain

$$(2) \quad \sim(\exists \phi)(\phi x) . \supset (\exists \phi)(\phi x)$$

by letting $\psi \hat{x}$ in (1) be, in particular, $\sim(\exists \phi)(\phi \hat{x})$; and from (2) it follows by a kind of *reductio ad absurdum* that for any given x we have $(\exists \phi)(\phi x)$. But on Russell’s view this proof will not do, for (1) ought to have been written

$$(3) \quad \psi!x \supset (\exists \phi)(\phi!x)$$

and here $\sim(\exists \phi)(\phi!x)$, not being itself predicative, is not a permissible substitution for $\psi!x$. It is worth noting, however, that our final conclusion, $(\exists \phi)(\phi!x)$, can be proved from (3) in a different way—by letting our $\psi!x$ be $\chi!x \supset \chi!x$ (“ \hat{x} χ ’s-if-it- χ ’s”), which *is* predicative and is true of any x , so that what it implies must be true of any x also. (The new argument is as follows: There is always some fact about x , since at least it is a fact that x is red-if-it-is-red, square-if-it-is-square, etc.)

Axiom of reducibility. Russell lumps together all his type and order restrictions under the general head of avoiding “vicious circles,” and the theory of types with the theory of orders worked into it is called the “ramified” theory of types. One trouble with it is that it vitiates certain essential arguments in the higher reaches of mathematics, and to save these Russell introduced an “axiom of reducibility,” that to every function of any order there corresponds a predicative function that is formally equivalent to it—that is, which holds for exactly the same arguments as the given function. This means that any argument like our allegedly invalid proof of $(\exists \phi)(\phi x)$ above, where it is worth saving, can in principle be replaced by one like our second and valid one; the axiom of reducibility does not itself enable us to find this valid argument but entitles us to proceed as if we had it. It is, however, an intuitively dubious principle and can be dispensed with if we can content ourselves with the theory

of types in the “simple” form in which it has been stated in earlier sections.

Semantic paradoxes. It was pointed out by F. P. Ramsey that those paradoxes which Russell lists and which cannot be eliminated (as can, for example, the paradox of the class of all classes not members of themselves) by the “simple” theory of types always contain some implicitly or explicitly “semantic” feature; that is, they all have to do with the relation of language to what it is about and all involve conceptions like truth and meaning. A typical example is the paradox of the liar, of the man who says “What I am now saying is false” and says nothing else but this, so that what he says is true if it is false and false if it is true. Such paradoxes are now generally dealt with by assuming not only a hierarchy of “parts of speech” in one’s basic language (this is what the simple theory of types amounts to) but also a hierarchy of languages—a basic language, a “metalanguage” in which we discuss the meaning and truth of expressions in the basic language, a “metametalinguage” in which we deal similarly with the metalanguage, and so on.

It is both easy and necessary to criticize Russell’s theories concerning the logical and semantic paradoxes, and his work in logic and the foundations of mathematics generally, but he remains, more than any other one person, the founder of modern logic.

ETHICS AND THE CRITIQUE OF RELIGION

ETHICS. Much of Russell’s life, as we saw in an earlier section, was devoted to the advocacy of certain moral and political ideals. In this sense of the word *moralist*, in which it has no derogatory implications, Russell was certainly a moralist and frequently a very passionate one at that. Unlike many other moralists he was also concerned with what are now referred to as “metamoral” or “metaethical” issues. He repeatedly addressed himself to questions about the status of moral principles—what, if anything, they mean, what kind of disagreement there is between people who support opposite moral positions, and whether inferences from nonmoral premises to a moral conclusion can ever be valid. In discussing Russell’s ethics, we will be concerned only with his metamoral theories.

Early views. In his first important essay on this subject, “The Elements of Ethics” (1910), Russell defended a position closely akin to that of G. E. Moore in *Principia Ethica*. “Good and bad,” he wrote, “are qualities which belong to objects independently of our opinions, just as

much as *round* and *square* do; and when two people differ as to whether a thing is good, only one of them can be right, though it may be very hard to know which is right.” The goodness or badness of a thing cannot be inferred from *any* of its other properties. “Knowledge as to what things exist, have existed, or will exist, can throw absolutely no light upon the question as to what things are good.” Russell was by no means unaware at this time of the wide appeal of the familiar arguments for subjectivism—the “divergence of opinion” on moral questions and the difficulty of “finding arguments to persuade people who differ from us in such a question” (“The Elements of Ethics,” in *Readings in Ethical Theory*, edited by Wilfrid Sellars and John Hospers, New York, 1952, pp. 6–7). But he did not then regard these arguments as having any logical force. “Difficulty in discovering the truth,” he wrote, “does not prove that there is no truth to be discovered” (p. 6). Like Moore, he argued that if subjectivism were true it would follow that in a moral dispute there is never really any “difference of opinion” between the disputing parties. If when *A* says *x* is good and *B* says *x* is bad, *A* and *B* were really talking about their respective feelings or desires, they might well both be right at the same time and “there would be no subject of debate between them.” At that time Russell regarded this as plainly false. “As a matter of fact,” he observed, “we consider some tastes better than others: we do not hold merely that some tastes are ours and other tastes are other people’s.” When “The Elements of Ethics” was reprinted in 1952 in *Readings in Ethical Theory*, the anthology mentioned above, Russell added a footnote in which he explained that “not long after publishing this paper [he] came to disagree with the theory that it advocates.” He explains that the change in his views was originally due to George Santayana’s criticisms in his *Winds of Doctrine*, but he adds that he “found confirmation” for his later position “in many other directions.” Russell’s later position was first mentioned very briefly in a 1921 preface to a paperback reprint of “A Free Man’s Worship”; it was explained in some detail in *What I Believe* (1925) and in *The Outline of Philosophy* (1927), and it received its fullest formulations in *Religion and Science* (1935), *Power* (1938), “Reply to My Critics” (in P. A. Schilpp, ed., *The Philosophy of Bertrand Russell*, 1944), and *Human Society in Ethics and Politics* (1955).

The subjectivity of values. Except on one basic issue, Russell’s later position is a point-by-point denial of the earlier theory. “Good” and “bad” are no longer regarded as qualities belonging to objects, and in this respect they are now explicitly contrasted with “square” and “sweet”: “If two men differ about values, there is not a disagree-

ment as to any kind of truth, but a difference of taste” (*Religion and Science*, pp. 237–238); “There are no facts of ethics” (*Power*, p. 257); “I see no property analogous to truth that belongs or does not belong to an ethical judgment” (“Reply to My Critics,” p. 723). “Taste” in the first of these passages is used in a very broad sense to cover all kinds of psychological states and attitudes, including desires. Russell does not, of course, deny the plain fact that people regard some tastes as better than others and some desires as higher than other desires, but now he is willing to maintain that this merely means that the tastes or desires are their own. “What we ‘ought’ to desire is merely what someone else wishes us to desire” (*What I Believe*, p. 29).

Russell is quite ready to have his later theory classified as a form of “the doctrine of the subjectivity of values” (*Religion and Science*, p. 237), but it differs in some significant respects from the older theories that have gone by that name. If somebody maintains that pleasure, for example, or the love of God, is intrinsically good, or good “on its own account,” this must not be taken to be equivalent to the statement that he approves of it or in some way desires it. Like the advocates of the so-called emotive theory of ethics, Russell maintains that intrinsic moral judgments, grammatical appearances notwithstanding, are not statements or assertions at all but *expressions* of desire. “A judgment of intrinsic value,” he writes in *Power*, “is to be interpreted, not as an assertion, but as an expression of desire concerning the desires of mankind. When I say ‘hatred is bad,’ I am really saying: ‘would that no one felt hatred.’ I make no assertion; I merely express a certain type of wish” (*Power*, p. 257).

Both here and in his capacity as a reformer Russell places much emphasis on the distinction between purely personal and what he calls “impersonal” desires. A hungry man’s desire for food or an ambitious man’s desire for fame are examples of the former; a desire for the abolition of the death penalty or the end of racial discrimination, independently of whether the person in question stands to gain from these changes, are examples of the latter. In moral judgments we express certain of our impersonal desires. A king who says, “Monarchy is better than republican forms of government,” is using the word *better* in its properly moral sense if he is expressing not just his desire to remain king but a desire that nations have monarchical systems regardless of his own personal position. Russell occasionally writes as if the desire expressed by moral judgments must be a second-order desire—that is, a desire that everybody have a certain first-order desire—but as several of his own examples make clear,

this is not part of his position. What is essential is that the desire be impersonal. In this connection he also observes that the philosophers who stressed the “universality” of moral principles were in a sense quite right. This universality, however, does not consist in any a priori character or logical necessity. What is universal is the *object of the desire* expressed by a moral judgment. “The wish, as an occurrence, is personal, but what it desires is universal.... It is this curious interlocking of the particular and the universal which has caused so much confusion in ethics” (*Religion and Science*, p. 236).

As we shall see, Russell had a tendency to overestimate the scope of application of his subjectivism, but in a number of places he points out quite explicitly that large classes of everyday moral judgments and disputes do not come within the purview of the theory. “Ethical controversies are very often as to means, not ends” (*Power*, p. 259). “The framing of moral rules, so long as the ultimate Good is supposed known, is matter for science” (*Religion and Science*, p. 228). It follows from this that if human beings could agree about ultimate ends, all moral disputes would in principle be decidable by an appeal to facts even though the intrinsic judgments would still be not bona fide propositions but expressions of wishes. In fact, however, Russell insists, there is no such agreement about ends. In “The Elements of Ethics” he had conceded that there were *some* ultimate ethical differences but had maintained that people in fact “differ very little in their judgments of intrinsic value.” Many of the commonly observed differences are wrongly regarded as ultimate because what are really disagreements about means are mistaken for disagreements about ends. In his subjectivist phase Russell seems to think that differences about ends are not at all uncommon. Behind such disputes as, for example, the subjection of women or the persecution of religious minorities, which do involve questions of means, he writes, “there is generally a difference as to ends,” and this sometimes becomes “nakedly apparent,” as in Friedrich Nietzsche’s criticisms of Christian ethics. In Christianity, all men are valued equally, but for Nietzsche the majority exists only as means to the superman. This, Russell maintains, is an example of a dispute about ends, and “it cannot be conducted, like scientific controversies, by appeals to facts” (*Power*, p. 259).

In “The Elements of Ethics” Russell had quite properly observed that the mere existence of widespread ethical disagreement (if it is indeed widespread) does not establish any form of subjectivism. Although he has evidently come to believe that ethical disagreement is more widespread than he had thought earlier, he does not offer

this as evidence for his new theory. What he does offer as evidence is the undecidability of ethical disputes. He writes:

[The chief ground for adopting this view] is the complete impossibility of finding any arguments to prove that this or that has intrinsic value.... We cannot *prove*, to a color-blind man, that grass is green and not red. But there are various ways of proving to him that he lacks a power of discrimination which most men possess, whereas in the case of values there are no such ways ... since no way can be even imagined for deciding a difference as to values, the conclusion is forced upon us that the difference is one of taste, not one as to any objective truth. (*Religion and Science*, p. 238)

If three men argue, one saying “The good is pleasure,” the second “The good is pleasure for Aryans and pain for Jews,” and the third “The good is to praise God and glorify him forever,” they cannot, as people engaged in a scientific dispute, “appeal to facts,” for facts, it seems obvious, “are not relevant to the dispute” (*Power*, p. 257).

Russell’s later view agrees with the earlier position on only one significant point, its opposition to naturalism. By “naturalism” is here meant the theory that there *is* a logical connection between some moral judgments and factual premises where the latter are not necessarily confined to empirical statements but may also include metaphysical doctrines. We saw how in “The Elements of Ethics” Russell had insisted that from statements concerning what exists nothing can be inferred about “the goodness of anything.” “It is logically impossible,” he repeated in the course of expounding his later position, “that there should be evidence for or against” a moral judgment, but now this is maintained because a moral judgment “makes no assertion” and hence possesses neither truth nor falsehood (*Religion and Science*, pp. 236–237).

“Incredibility” of Russell’s subjectivism. Rather than attempt a detailed critical evaluation of Russell’s subjectivism, we will discuss one objection that has been urged by a number of his critics and which, in one form or another, has been leveled against nearly all forms of subjectivism. It has been argued that a subjectivist cannot consistently make moral judgments. All he can say is that some people have one kind of feeling or attitude while other people feel differently. More specifically, how can Russell’s subjectivism be reconciled with his judgments as a moral critic and reformer?

It may be replied that as a matter of pure logic there is no inconsistency between holding that moral judgments are expressions of taste and using moral language to express one’s own tastes. Russell, it might be said, would be inconsistent only if he claimed that *his* moral judgments, unlike those of his opponents, are more than expressions of taste. Then he would indeed be like the man who, in the course of an argument about the value of a piece of music, remarked to his opponent “It is all a matter of taste, except that my taste is better than yours.” However, while this answer is valid as far as it goes, it does not meet the heart of the objection. For Russell seems to be saying—or at least he would like to be able to say—that his moral judgments (for example, his judgment that democracy is a better system than totalitarianism or that the sexual code advocated in *Marriage and Morals* is superior to that associated with orthodox religion) are in some sense rational or right or well-grounded while the judgments of his opponents are irrational, wrong, or unsupported by the evidence.

Russell apparently did not, when he first advanced his subjectivism, see any serious problem here, but in the 1940s and 1950s he repeatedly expressed dissatisfaction with his own theory on this ground. Thus, in “Reply to My Critics” he writes:

What are “good” desires? Are they anything more than desires that you share? Certainly there *seems* to be something more. Suppose, for example, that some one were to advocate the introduction of bull-fighting in this country. In opposing the proposal, I should *feel*, not only that I was expressing my desires, but that my desires in the matter are *right*, whatever that may mean. As a matter of argument, I can, I think, show that I am not guilty of logical inconsistency in holding to the above interpretation of ethics and at the same time expressing strong ethical preferences. But in feeling I am not satisfied. (*The Philosophy of Bertrand Russell*, p. 724)

To this he adds: “I can only say that, while my own opinions as to ethics do not satisfy me, other people’s satisfy me still less.” More than a decade later Russell expressed himself even more strongly. In a letter to the *Observer* (October 6, 1957) he comments on Philip Toynbee’s review of *Why I Am Not a Christian*: “What Mr. Toynbee says in criticism of my views on ethics has my entire sympathy. I find my own views argumentatively irrefutable, but nevertheless incredible. I do not know the solution.”

It is doubtful whether in such comments Russell is really fair to his own subjectivism. Let us recall that the

theory was never meant to apply to anything other than what are variously called intrinsic or fundamental value judgments and differences. The questions whether happiness is better than unhappiness and love better than hate are frequently cited as such ultimate moral issues, but it would be hard to find anybody who seriously maintains that suffering is good on its own account or that hate is better than love, although of course people have often maintained that in certain situations and for certain reasons suffering and hate are preferable to enjoyment and love. However, on occasions there do appear to be real value differences of an ultimate kind. Thus, some people would maintain that dignity is “more important” or “nobler” than happiness. Many who do not despise happiness at all would maintain without hesitation that a man who chose to suffer a great deal rather than compromise his integrity (where it is assumed that he would in fact have suffered much less if he had not stood his ground) lived a better life than he would have if he had made the opposite choice. Or, again, there is sometimes disagreement as to whether a person suffering from a fatal illness should be told the truth, although there may be full agreement about the consequences of both telling and not telling him the truth. Russell’s subjectivism does apply to this kind of intrinsic moral disagreement, and in such situations he could not, consistently with his theory, claim that the moral judgment he endorses is “more rational” or better supported than that of his opponents.

However, the examples Russell offers when expressing dissatisfaction with his subjectivism are not at all of this ultimate kind, and this applies to all or nearly all the positions he has advocated in his social and political writings. The man who says that the good is pleasure for Aryans and pain for Jews, if he is willing to engage in moral argument at all—if he is not, the problem does not arise—presumably does not *just* say this but proceeds to make all kinds of factual claims about the psychological and physical qualities of Aryans and Jews, respectively, about the laws of heredity, and about various other matters that he regards as justifying his moral position. Similarly, the man who maintains that “the good is to praise God and glorify him forever” presupposes that there is a God, and a God of a certain kind, probably also that he has revealed himself in certain ways, and, if challenged (or perhaps even without being challenged), he will make claims about the hollowness of all earthly satisfactions and the greater reliability, intensity, and duration of the satisfactions derived from glorifying God. Again, a man, who advocates the introduction of bullfighting into the United States would not *just* advance this proposal but would give reasons having to do, perhaps, with the bene-

fits to be derived from engaging in dangerous sports and the special thrills experienced by the spectators. All these supporting factual claims are discussable, and it may be possible to show that they are mistaken or highly implausible. If so, it might well be possible to regard the case of one side in such a dispute as well supported and the other as unsupported by the evidence. In all cases in which the person is willing to support his moral judgment by factual premises, it is perfectly consistent for Russell to assert that one position is “more rational” than the other, where “more rational” does not merely mean that Russell shares the attitude of the person taking this position.

What seems to be amiss here is not Russell’s subjectivism but his view (which is not logically implied by it) that the theory applies to cases like the dispute about bullfighting. In his later period Russell seems to be guilty of a gross overestimate of the prevalence of ultimate moral disagreements. It is true, as he observes in *Power*, that behind disagreements about means there is frequently disagreement about ends, but it is very doubtful that the ends in question are in most cases *ultimate* ends. To give a simple illustration of a very common type: Two people may offer conflicting moral judgments about a bill to legalize abortion. The man who opposes the legislation may give as his reason (or as one of his reasons) that it would remove one of the conditions restraining unmarried people from engaging in sexual intercourse, whereas the other man might offer this as his reason (or one of his reasons) for supporting the legislation. Although the disagreement may in the immediate context be properly described as one about an end, it is clearly not about an ultimate end. In all likelihood the parties to the dispute would differ about the effects of a freer sex life on personal happiness, on society at large, on the future of religious institutions, and many other things. It is doubtful that either of them would maintain that suffering as such is better than happiness or that hate is better than love.

Even people who advocate what by most contemporary standards would be regarded as “outlandish” moral positions can usually be seen to share many of the intrinsic value judgments of the rest of humankind. Thus, Arthur Schopenhauer and other champions of asceticism recommend the suppression of desires, including those that to most human beings seem the most natural and the most innocent, but they do so *not* because in their opinion suppression of these desires would make people unhappy but, on the contrary, because it would enable them to achieve greater happiness or at least because it would reduce suffering to a minimum. In Norman Mailer’s bizarre novel *An American Dream* the main char-

acter offers a defense of murder, but this unusual position is justified by the argument that “murder offers the promise of vast relief. It is never unsexual.” It is accompanied by “exhilaration” that must come “from possessing such strength.” It should be noted that murder is here justified not because it causes suffering but because, according to the character, it leads to “exhilaration.” In other writings Mailer tells us that the “modern soul marooned in ... emptiness, boredom and a flat, dull terror of death” would be well advised to pass through “violence, cannibalism, insanity, perversion” and other states and activities that are usually considered highly undesirable, but these recommendations are offered not for their own sake but because they will lead the person “back to life.”

As for the really intrinsic clashes of the kind mentioned earlier, to which Russell’s subjectivism would apply, one wonders if the consequences of the theory are there really so paradoxical. No doubt people do in such disputes regard their position as superior to that of their opponents—the man who admires integrity will feel contempt for the “cowardly” compromiser, and the compromiser will think the man who chooses to suffer a fool. Here, however, unless there are some *hidden* differences concerning matters of fact, it seems not at all incredible to maintain that calling one position superior simply amounts to expressing one’s own preference for it.

None of the above is meant to prove that Russell’s subjectivism is a correct account of the logical status of moral judgments, but it would indicate that the favorite objection of his critics can be disposed of without much difficulty.

CRITIQUE OF RELIGION. No such doubts as Russell has expressed about his subjectivism in ethics mark his views on religion. Unlike many academic philosophers whose position is very similar to his, Russell did not hesitate to express his convictions publicly and without equivocation or compromise. Ever since he abandoned the Platonic theory of ideas, Russell was a forthright opponent of religion in more senses than one: He regards the basic doctrines of (supernaturalistic) religions as intellectually indefensible, he argues that religious belief has not on balance been a force for good but quite the opposite, and he hopes and believes that religion will eventually die out. “I am myself,” he wrote in 1922, “a dissenter from all known religions, and I hope that every kind of religious belief will die out.... I regard religion as belonging to the infancy of human reason and to a stage of development which we are now outgrowing” (*Sceptical Essays*, p. 101). In a television interview thirty-seven years later he

slightly qualified this prediction. If great wars and great oppressions continue so that many people will be leading very unhappy lives, religion will probably go on, but “if people solve their social problems religion will die out” (*Bertrand Russell Speaks His Mind*, p. 31).

God. Russell wavered between calling himself an agnostic and describing himself as an atheist. He evidently did not attach too much importance to this distinction, but he had made it clear that if he is to be classified as an agnostic, it would have to be in a sense in which an agnostic and an atheist are “for practical purposes, at one.” In the television interview mentioned earlier the interviewer asked Russell, “Do you think it is certain that there is no such thing as God, or simply that it is just not proved?” “No,” Russell answered, “I don’t think it is certain that there is no such thing—I think that it is on exactly the same level as the Olympic gods, or the Norwegian gods; they also may exist, the gods of Olympus and Valhalla. I can’t prove they don’t, but I think the Christian God has no more likelihood than they had. I think they are a bare possibility” (*Bertrand Russell Speaks His Mind*, pp. 24–25). He explained his views more fully in an interview published in *Look* magazine in 1953. An agnostic, in any sense in which he can be regarded as one, Russell said, “may hold that the existence of God, though not impossible, is very improbable; he may even hold it so improbable that it is not worth considering in practice” (Leo Rosten, ed., *A Guide to the Religions of America*, New York, 1955, p. 150).

Immortality. On survival, Russell’s position is similarly negative. All the evidence indicates that what we regard as our mental life is “bound up with brain structure and organized bodily energy.” There is every reason to believe that mental life ceases when the body decays. Russell admits that this argument is “only one of probability” but adds that “it is as strong as those upon which most scientific conclusions are based” (*Why I Am Not a Christian*, p. 51). It is conceivable that evidence from psychological research might change the balance of probability some day, but, writing in 1925, Russell considered such evidence far weaker “than the physiological evidence on the other side.” He did not later see any reason to modify this judgment.

Russell’s views on the body-mind problem are known as “neutral monism,” and it would be inaccurate to call him a materialist. However, he always emphasized that as a theory about man’s place in the universe his philosophy is closely akin to materialism. “Emotionally,” he wrote in 1928, “the world is pretty much the same as it would be if the materialists were in the right” (*In Praise of*

Idleness, p. 143). The opponents of materialism, he adds, have been actuated by the desire to prove that the mind is immortal and that the “ultimate power” in the universe is mental and not physical. On both these points, Russell makes clear, he agrees with materialism. When he returned to the subject in 1959 he had not changed his opinion at all. “I still think,” he wrote then, “that man is cosmically unimportant, and that a Being, if there were one, who could view the universe impartially, without the bias of *here* and *now*, would hardly mention man, except perhaps in a footnote at the end of the volume” (*My Philosophical Development*, p. 213).

Objections to fideism. Although, needless to say, Russell rejected the traditional arguments for the existence of God and immortality, he greatly preferred the rationalistic theology of such philosophers as Thomas Aquinas and Descartes to the fideism of Blaise Pascal, Jean-Jacques Rousseau, Søren Kierkegaard, and their numerous modern followers. “The rejection of reason in favor of the heart,” he writes, “was not, to my mind, an advance.” He remarks that “no one thought of this device so long as reason appeared to be on the side of religious belief” (*A History of Western Philosophy*, p. 720). There are two fatal objections to the practice of justifying religious belief by an appeal to the emotions of the heart. To begin with, the heart says different things to different men and to the same man at different times, but even if the heart said the same thing to all men this would still not be evidence for the existence of anything outside our emotions, and the fideists, no less than the rationalistic believers, mean to make claims about objective fact, not merely about their own emotions. At bottom, Russell concludes, the only reason offered for the acceptance of the new theology is “that it allows us to indulge in pleasant dreams. This is an unworthy reason, and if I had to choose between Thomas Aquinas and Rousseau, I should unhesitatingly choose the Saint” (*My Philosophical Development*, p. 721).

Some unbelievers have gone out of their way to praise the greatness of Jesus and to admit that religious belief, although perhaps not true, is at least of great value to individual believers and to society. Russell makes no such concessions. Although he grants that some of Christ’s maxims were indeed admirable (especially those consistently disregarded by Christian dignitaries) he finds much in the teachings of Jesus to be defective, in particular his doctrine of eternal damnation. “Either in the matter of virtue or in the matter of wisdom,” Russell concludes, Christ does not “stand as high as some other people known to history”—for example, Buddha and Socrates (*Why I Am Not a Christian*, p. 19).

Harmfulness of religious belief. Russell’s views about the nature of the emotions that inspire religious belief (“it is based, primarily and mainly, upon fear”) and also about the harmful influence of religious organizations are very similar to those of David Hume, Baron d’Holbach, and other eighteenth-century freethinkers. He did, however, devote rather more attention to the bad effects of the habit of accepting propositions on faith—in the absence of or even in opposition to the evidence. It is an error, Russell contends, to suppose that a person who does not form his beliefs on the basis of evidence in one domain can remain open-minded and scientific in another. Furthermore, somebody holding comfortable beliefs on faith dimly realizes that they are myths and “becomes furious when they are disputed.” Such a person will therefore do his best to suppress all critics who might remind him of the feeble backing of his beliefs. Russell makes it clear that in this context he is not criticizing Christianity only. “The important thing,” he writes, “is not what you believe, but how you believe it.” The objections to “faith” do not depend on what the faith in question may be. “You may believe in the verbal inspiration of the Bible or of the Koran or of Marx’s *Capital*. Whichever of these beliefs you entertain, you have to close your mind against evidence; and if you close your mind against evidence in one respect, you will also do so in another, if the temptation is strong.” The person who bases his belief on reason will support it by argument rather than by persecution and will abandon his position if the argument goes against him. If, however, his belief is based on faith, he will conclude that argument is useless and will “therefore resort to force either in the form of persecution or by stunting and distorting the minds of the young whenever he has the power to control their education” (*Human Society in Ethics and Politics*, pp. 207–208).

“The world is horrible.” Russell never denied that in some respects a “godless” philosophy like his has to be gloomy. The beginning of wisdom, he teaches, is acceptance of the fact that the universe does not care about our aspirations and that happiness and unhappiness are not meted out in accordance with what people deserve. “The secret of happiness,” he observed during a television program commemorating his ninety-second birthday, “is to face the fact that the world is horrible.” What Russell meant by this becomes clear from a story related by his biographer, Alan Wood. Wood’s wife had expressed her opinion that it seemed horribly unjust that the young men who had been killed in the war should not somehow or somewhere have a second chance to achieve happiness. “But the universe *is* unjust,” Russell replied, “the secret of happiness is to face the fact that the world is horrible,

horrible, *horrible* ... you must feel it deeply and not brush it aside ... you must feel it right here”—hitting his breast—“and then you can start being happy again” (*Bertrand Russell: The Passionate Sceptic*, p. 237). Once a person has stopped looking at the universe in terms of anthropomorphic demands, he can concentrate on what is attainable and not waste his time in self-pity and cosmic complaints. For those whose philosophy is shaped not by a respect for facts but by their wishes Russell was always scathing in his contempt. He expressed his amazement that courage is praised in all types of situations but not when it comes to forming a view about the world. “Where traditional beliefs about the universe are concerned,” he writes, “craven fears ... are considered praiseworthy, while intellectual courage, unlike courage in battle, is regarded as unfeeling and materialistic.” Writing in 1957, he notes that this attitude is perhaps less widespread than it was in his youth, but he adds that it “still inspires vast systems of thought which have their root in unworthy fears.” “I cannot believe,” he concludes, that there can ever be any good excuse for refusing to face the evidence in favor of something unwelcome. It is not by delusion, however exalted, that mankind can prosper, but only by unswerving courage in the pursuit of truth” (*Fact and Fiction*, p. 46).

Bibliography

BIOGRAPHY

There is a good deal of autobiographical material in Russell's *Portraits from Memory and Other Essays* (New York: Simon and Schuster, 1956); in *Fact and Fiction* (New York: Simon and Schuster, 1962); in his introduction to *Selected Papers of Bertrand Russell* (New York: Modern Library, 1927); in “My Religious Reminiscences,” in *Rationalist Annual* 55 (1938): 3–8; in “My Mental Development,” in *The Philosophy of Bertrand Russell*, edited by P. A. Schilpp (Evanston and Chicago: Open Court, 1944); and in *My Philosophical Development* (New York: Simon and Schuster, 1959). Alan Wood, *Bertrand Russell: The Passionate Sceptic* (London: Allen and Unwin, 1957), is the only full-length biographical study of Russell. H. W. Leggett, *Bertrand Russell* (New York, 1950), is a short pictorial biography.

- G. H. Hardy, *Bertrand Russell and Trinity* (Cambridge, U.K.: Cambridge University Press, 1942), traces the controversy between Russell and the fellows of Trinity College over his pacifist activities during World War I. *Rex versus Bertrand Russell, Report of the Proceedings before the Lord Mayor* (London, 1916), gives the text of the first of Russell's trials.
- D. H. Lawrence, *Letters to Bertrand Russell* (New York: Gotham Book Mart, 1948), reproduces Lawrence's letters to Russell during World War I; Russell's letters to Lawrence have not been preserved.

Russell's part in the Beacon Hill School is most fully described in Joe Park, *Bertrand Russell on Education* (Columbus: Ohio State University Press, 1963). The Park volume also contains a complete list of Russell's writings on educational topics. Details about the City College case of 1940 can be found in *The Bertrand Russell Case*, edited by John Dewey and Horace M. Kallen (New York: Viking Press, 1941); in a publication by the American Civil Liberties Union titled *The Story of the Bertrand Russell Case—The Enlightening Record of the Obstruction by Courts and Officials of the Appointment of Bertrand Russell to a Professorship at the College of the City of New York* (New York: American Civil Liberties Union, 1941); and in Paul Edwards, “How Bertrand Russell Was Prevented from Teaching at City College,” which is an appendix to Russell's *Why I Am Not a Christian and Other Essays on Religion and Related Subjects* (London: Allen and Unwin, and New York: Simon and Schuster, 1957).

EPISTEMOLOGY AND METAPHYSICS

Principles of Mathematics (Cambridge, U.K.: Cambridge University Press, 1903) was Russell's first major philosophical work. Its position is one of Platonic realism. In the preface to the second edition (1937) Russell sets forth his later disenchantment with this position. For a nonmathematical exposition of Russell's early realism, see “Meinong's Theory of Complexes and Assumptions,” in *Mind* 13 (1904): 204–219; 336–354; 509–524. Russell's criticisms of the idealist theory of truth are to be found in “The Monistic Theory of Truth,” in *Philosophical Essays* (New York: Longman, 1910), a revised version of “The Nature of Truth,” in *Mind* 15 (1906): 528–533. *Philosophical Essays* also contains two influential essays by Russell attacking the pragmatist theory of truth.

The shift from realism to logical constructionism can be followed in a number of articles, the most important of

which is "On Denoting," in *Mind* 14 (1905): 479–493. This, together with other important but otherwise largely unavailable essays, is reprinted in Russell's *Logic and Knowledge*, edited by R. C. Marsh (London: Allen and Unwin, 1956). Russell's "On the Relations of Universals and Particulars," in *PAS* 12 (1911–1912): 1–24, reprinted in *Logic and Knowledge*, is a classic presentation of the largely Platonic theory of universals Russell still held at that time. *Problems of Philosophy* (New York: Holt, 1912) gives an excellent semipopular account of the general state of Russell's thinking then. Russell's early attempts to represent physical objects as logical constructions can be seen in *Our Knowledge of the External World* (Chicago: Open Court, 1914) and in two essays, "The Ultimate Constituents of Matter," in *Monist* 25 (1915): 399–417, and "The Relations of Sense-Data to Physics," in *Scientia* (4) (1914), both reprinted in *Mysticism and Logic* (London: Allen and Unwin, 1918). Other important essays in this collection are "On Scientific Method in Philosophy" (1914); "On the Notion of Cause," originally published in *PAS* 13 (1912–1913): 1–26; and "Knowledge by Acquaintance and Knowledge by Description," originally published in *PAS* 11 (1910–1911): 108–128. See also "The Philosophy of Logical Atomism," in *Monist* 28 (1918): 495–527; 29 (1919): 32–63, 190–222, and 345–380; reprinted in *Logic and Knowledge* (see above). The analysis of basic concepts and principles of physical science is pushed further in *The Analysis of Matter* (New York: Harcourt Brace, 1927). Logical constructionism is applied to mental phenomena in *The Analysis of Mind* (New York: Macmillan, 1921). Russell's increasing concern with psychological aspects of meaning can be traced in "On Propositions, What They Are and How They Mean," in *PAS*, supp. 2 (1919): 1–43, reprinted in *Logic and Knowledge*, in Ch. 10 of *The Analysis of Mind*; and in Russell's most extensive work on meaning and empirical data, the rich but chaotic *An Inquiry into Meaning and Truth* (New York: Norton, 1940). Russell's later thoughts on meaning and various other problems concerning empirical knowledge, particularly in the physical sciences, are given a relatively systematic presentation in *Human Knowledge, Its Scope and Limits* (New York: Simon and Schuster, 1948).

In several works Russell summarized his philosophy and/or its development. The most important of these are "Logical Atomism," in *Contemporary British Philosophy*, edited by J. H. Muirhead, first series (London: Allen and Unwin, 1924), reprinted in *Logic and Knowledge* (see above); "My Mental Development," in *The Philosophy of Bertrand Russell*, edited by P. A. Schilpp (see above); and the very interesting recent work *My Philosophical Development* (New York: Simon and Schuster, 1959). The last-named work also contains some of Russell's polemics against Oxford philosophers and their criticisms of his views. Russell's *A History of Western Philosophy* (New York: Simon and Schuster, 1946) and *The Wisdom of the West* (New York: Doubleday, 1959), aside from their intrinsic interest, are of great value to students of Russell's thought in showing us his mature evaluations of the great philosophers of past ages.

The critical literature on different aspects of Russell's epistemology and metaphysics is vast. *The Philosophy of Bertrand Russell* (see above) contains a number of excellent discussions, together with Russell's replies. Special mention should also be made of C. A. Fritz, *Bertrand Russell's*

Construction of the External World (London: Routledge & K. Paul, 1952); Erik Götlind, *Bertrand Russell's Theories of Causation* (Uppsala: Almqvist and Wiksells, 1952); J. O. Urmson, *Philosophical Analysis: Its Development between Two World Wars* (Oxford: Clarendon Press, 1956); and G. J. Warnock, *English Philosophy since 1900* (London: Oxford University Press, 1958). The books by Urmson and Warnock contain detailed appraisals of Russell's logical atomism. Russell's logical atomism as well as his neutral monism and his theories about truth and induction are sympathetically discussed by D. J. O'Connor in Ch. 26 of his *Critical History of Western Philosophy* (New York: Free Press of Glencoe, 1964). *Rivista critica di storia della filosofia* 8 (2) (1953): 101–335, and several articles in *Philosophy* 35 (January 1960): 1–50, are devoted to Russell's philosophy, including Anthony Quinton's useful sketch of the development of Russell's ideas in epistemology and metaphysics, "Russell's Philosophical Development," 1–13.

LOGIC AND MATHEMATICS

- Of Russell's own works on logic and mathematics, see *Principles of Mathematics* (Cambridge, U.K.: Cambridge University Press, 1903; 2nd ed., London, 1937); *Principia Mathematica*, 3 vols., written with A. N. Whitehead (Cambridge, U.K.: Cambridge University Press, 1910–1913; 2nd ed., 1927); *Introduction to Mathematical Philosophy* (London: Allen and Unwin, 1919); and the papers "On Denoting" (1905), "Mathematical Logic as Based on the Theory of Types" (1908), "The Philosophy of Logical Atomism" (1918), and "Logical Atomism" (1924), all of which are reprinted in *Logic and Knowledge* (see above).
- On Frege's parallel work, see his *Grundlagen der Arithmetik* (Breslau, 1884), translated by J. L. Austin as *The Foundations of Arithmetic* (Oxford: Blackwell, 1950); and P. T. Geach and Max Black, eds., *Translations from the Philosophical Writings of Gottlob Frege* (New York: Philosophical Library, 1952).
- Important critical discussions of Russell's work occur in W. E. Johnson, *Logic*, Pt. II (Cambridge, U.K., 1922), Chs. 3 and 6; F. P. Ramsey, *The Foundations of Mathematics* (London, 1931), papers I and II; W. V. Quine, *From a Logical Point of View* (Cambridge, MA: Harvard University Press, 1953), essays I, V, and VI; and G. E. Moore, *The Commonplace Book of G. E. Moore, 1919–1953*, edited by Casimir Lewy (New York: Humanities Press, 1963), Notebook II, item 4, and Notebook V, item 13.
- On formal implication, see A. N. Prior, "The Theory of Implication," in *Zeitschrift für mathematische Logik und Grundlagen der Mathematik* 9 (1963): 1–6. On simplifications of type theory, see Alonzo Church, "A Formulation of the Simple Theory of Types," in *Journal of Symbolic Logic* 5 (1940): 56–68, and Ludwik Borkowski, "Reduction of Arithmetic to Logic Based on the Theory of Types," in *Studio Logica* 8 (1958): 283–295.

ETHICS AND RELIGION

Russell's early views on ethics are in "The Elements of Ethics," Ch. 1 of *Philosophical Essays* (New York: Longman, 1910); it has been reprinted in *Readings in Ethical Theory*, edited by Wilfrid Sellars and John Hospers (New York: Appleton-Century-Crofts, 1952), pp. 1–34. The fullest statements of his later position are in Ch. 9 of *Religion and Science* (New York: Holt, 1935) and in *Human Society in Ethics and Politics* (New York: Simon and Schuster, 1955). There are critical

discussions of Russell's views in Lillian W. Aiken, *Bertrand Russell's Philosophy of Morals* (New York: Humanities Press, 1963); in Justus Buchler, "Russell and the Principles of Ethics," in *The Philosophy of Bertrand Russell* (see above); and in D. H. Monro, "Russell's Moral Theories," in *Philosophy* 35 (1960): 30–50.

Russell's earlier views on religion are in "The Essence of Religion," in *Hibbert Journal* 11 (1912): 46–62. His first published discussion of the arguments for the existence of God is contained in Ch. 15 of *A Critical Exposition of the Philosophy of Leibniz* (Cambridge, U.K.: Cambridge University Press, 1900; 2nd ed., London and New York, 1937). His later views are expounded in several of the essays in *Why I Am Not a Christian* (see above) and in Pt. II, Ch. 7, of *Human Society in Ethics and Politics* (see above). The BBC debate with Father F. C. Copleston (1948), "The Existence of God," is available in the British edition, but not in the American edition, of *Why I Am Not a Christian*, but it has been reprinted in *A Modern Introduction to Philosophy*, edited by Paul Edwards and Arthur Pap, 2nd ed. (New York, 1965), and in *The Existence of God*, edited by John Hick (New York: Macmillan, 1964). Several chapters in *The Scientific Outlook* (London and New York, 1931) and in *Religion and Science* (see above) contain criticisms of the attempts of certain scientists to derive theological conclusions from physics and biology. Russell's objections to the fideistic position are found in Ch. 12, Bk. 3, of *A History of Western Philosophy* (see above). His objections to William James's defense of religion are contained in Ch. 29, Bk. 3, of the same work and in Ch. 5 of *Philosophical Essays* (see above). Russell's views on religion are criticized in H. G. Wood, *Why Mr. Bertrand Russell Is Not a Christian* (London, 1928); C. H. D. Clark, *Christianity and Bertrand Russell* (London: Lutterworth Press, 1958); G. S. Montgomery, *Why Bertrand Russell Is Not a Christian* (New York, 1959); and E. S. Brightman's contribution to the Schilpp volume, "Russell's Philosophy of Religion," pp. 537–556.

SOCIAL AND POLITICAL THEORY

In addition to the works mentioned in the first section of the present entry, the following among Russell's books dealing with social and political questions have been influential: *Principles of Social Reconstruction* (London: Allen and Unwin, 1916); *Roads to Freedom: Socialism, Anarchism and Syndicalism* (London: Allen and Unwin, 1918); *The Problems of China* (New York: Century, 1922); *Power: A New Social Analysis* (London: Allen and Unwin, 1938); *Authority and the Individual* (London: Allen and Unwin, 1949); and *New Hopes for a Changing World* (London: Allen and Unwin, 1951). Ch. 17 of *New Hopes* contains a moving discussion of the problems of growing old and facing death. Russell's fullest discussion of Marxism can be found in *Freedom and Organization 1814–1914* (London: Allen and Unwin, 1934); as *Freedom versus Organization*, New York, 1934), which is in effect a history of the main social and intellectual forces of the nineteenth century.

OTHER WRITINGS

Philosophical discussions sooner or later crop up in most of Russell's writings. Some of his most delightful occasional pieces have been collected in *Sceptical Essays* (London: Allen and Unwin, 1927); in *In Praise of Idleness* (London: Allen and Unwin, 1935); and in *Unpopular Essays* (London: Allen

and Unwin, 1950). The last of these contains his "Auto-biography," which was first published in 1936. *Bertrand Russell Speaks His Mind* (London: Barker, 1960) is a most interesting volume containing the unedited text of a series of television interviews, dealing with a great variety of topics, which took place in the spring of 1959.

The Basic Writings of Bertrand Russell, 1903–1959, edited by R. E. Egner and L. E. Dennon (New York, 1961), is a very useful anthology of writings by Russell. The Schilpp volume contains an extremely comprehensive bibliography up to 1944.

RUSSIAN PHILOSOPHY

In the broad sense the words “Russian philosophy” refer to all schools of philosophical thought pursued in Russia, regardless of differences among them. In the narrower sense the terms describe the religious-philosophical trend that flourished in the late nineteenth and early twentieth centuries. Both uses have value: The first embraces the variety of interests among Russian philosophers, whereas the second points to their most distinctive contribution to philosophy in general. But even on the broadest level, the common preoccupations that were typical of major Russian thinkers shaped the physiognomy of Russian philosophy as a whole.

Philosophy in Russia developed in a variety of forms. Philosophical ideas permeated religious, political, and literary debates throughout the country’s history. For a long time they were not articulated in what counted as philosophical parlance in the West, largely because of unfavorable historical conditions. But when these conditions changed, as they did, for example, in the late nineteenth and especially in the early twentieth centuries, there emerged a vibrant philosophical scene. This flourishing had been prepared within Russian culture, among other things, by its religious, literary, and scientific thought. Thus it should not be surprising that some theologians, novelists, and scientists are relevant to the history of Russian philosophy.

TYPICAL FEATURES

For various reasons Russian philosophy has been dominated, not to say oppressed, by pragmatic concerns. Realistic or utopian, philosophical thought in Russia is expected to be engaged. It is not an accident that Marxism, for which social practice is the criterion of theoretical truth, has had such a firm grip on the Russian polity. Even when Russian philosophy did reach the heights of speculation—as in the thought of Vladimir Solov’ev (1853–1900)—it still bore the mark of “theurgic restlessness,” in Vasilii Zen’kovskii’s (1881–1962) words—that is, the desire to transfigure life. Still, when conditions were right, and sometimes despite harshly adverse conditions, Russian thinkers have achieved reflexive insights of uncommon depth.

Closely related to this is Russian philosophy’s realist *ontologism*; that is, the tendency to value the reality of *being* over and above the truths of abstract *understanding*. Nikolai Berdyaev (1874–1948) noted that the Russian mind strongly doubts whether the creation of culture is justified in the face of life’s problems. This doubt was typ-

ical of Lev Tolstoy (1828–1910) who disparaged art in contrast with the peasant’s work. Paradoxically, this tendency was also responsible for the seriousness with which Russians have treated the arts and philosophy. Likewise Russian thinkers often sought *justice* more eagerly than *truth* because the former seemed more tangible and urgent than the latter.

Many commentators have insisted that Russian philosophy is also inherently religious and personalistic. While the aggressively atheist and collectivist Soviet Marxism is an inescapable counterexample, it cannot be denied that the themes of religion and personhood have occupied and continue to occupy a prominent place in Russian philosophical discourse. Fëdor Dostoevsky’s (1821–1881) persistent interest is only the more familiar, especially to the West, among many manifestations of these themes.

Russian thought has a marked predilection for viewing things holistically. Russian philosophers have often been preoccupied with global, wide-ranging problems and visions of all existence as an integral whole. In metaphysics this trait is responsible for Solov’ev’s doctrine of all-unity. On the opposite end, this holism transmogrified into totalitarianism for which Stalinism stands as the most ominous example.

The evolution of philosophical ideas in Russia has been shaped by the persistent Slavophile-Westernist dichotomy; that is, tension between the impulses, on the one hand, toward national uniqueness and, on the other, toward closer affiliation with the West. However, from the earliest time these tendencies were so closely intertwined with each other that any attempt at a simple delineation is misleading.

And, finally, there is in Russian thought what Berdyaev called the “eschatological” orientation that can also be described as striving toward limits—in particular, the limits of thinking and of intelligibility of things. Like all the other features, this one also has had two opposite consequences. On the one hand, it makes Russian thought philosophically inclined in general, for it pushes rational enquiry to dwell persistently on ultimate questions. On the other hand, such a passion for limits could encourage, as it did in Berdyaev’s own case, impatience with careful argumentation.

HISTORICAL EVOLUTION

Russian philosophical thought cannot be properly understood apart from its historical development. Its constant and eager immersion in cultural, social, and political con-

texts, as well as its stubborn continuity, make a historical perspective necessary for grasping both the problems that it grappled with and the solutions that it proposed.

KIEVAN PERIOD. Philosophical ideas, properly so called, first appeared in Russia when Christianity was introduced in 988 by the Kievan Prince Vladimir. The prior, polytheistic view of the world was partially replaced with the Christian outlook, resulting in the fertile amalgam of Eastern Orthodoxy and Slavonic paganism called “dual faith” (*dvoeverie*).

Universities and academic philosophy did not appear in Russia until the eighteenth century, nor was there a direct engagement with ancient Greco-Roman thought of the sort that shaped western medieval learning. Nascent Russian literature absorbed from Byzantium a number of early patristic writings, particularly those of the Cappadocian Fathers, in the form of religious-dogmatic texts translated from Greek into Church Slavonic. Anthologies comprising the writings of John Chrysostom, Gregory of Nazianzus, Basil the Great, Gregory of Nyssa, and John of Damascus introduced Russians to Christian Neoplatonist cosmology, metaphysical anthropology, and allegorical exegesis. Kievan Rus also imported the veneration of Sophia Divine Wisdom that found expression in architecture, icon-painting, and hymns.

In the mid-eleventh century this learning began to bear fruit when the first Russian Metropolitan of Kiev Ilarion described in his “Sermon on Law and Grace” history in terms of contrast between the law of the Old and the grace of the New Testaments, and argued the equal standing of Kievan Rus among Christian nations. Moral ideas were disseminated through “instructions” (*poucheniia*) for righteous living that often contained philosophical ideas derived from ancient and Byzantine thought. Throughout the premodern period philosophy in Russia was viewed primarily as *ancilla fidei* and a path toward religious illumination. At the same time it was understood in broad terms: Plato, Fathers of the Church, and even certain icon painters were considered “philosophers.”

Around the mid-thirteenth century this early flourishing was interrupted by the Mongol invasion. Bishop Serapion, who witnessed the sack of Kiev in 1240, was a proponent of the view that history was a series of catastrophes visited by God upon humanity for its sins. With Kiev devastated by the invasion, the center of religious and cultural life shifted to Vladimir and Moscow in the forested northeast that was less vulnerable to attack from the steppes.

MUSCOVITE PERIOD. In the fourteenth century the influence of hesychasm became pronounced, especially through the activities of St. Sergii of Radonezh (1314/22–1391/92). The Trinity-Sergius Monastery near Moscow that he founded soon rivaled Kiev’s Monastery of the Caves as Russia’s main religious center. St. Sergii’s popularity and influence signaled the rebirth of Russian culture around the Grand Duchy of Moscow that in 1380 successfully challenged the Mongol rule. The icon painter Andrei Rublev (d. c. 1430), whose art had a marked contemplative quality, was another representative of this cautious revival. In 1371 the translation of the Areopagitic corpus appeared that had a lasting impact on medieval Russian thought. (More than seventy copies of this work dating to the sixteenth and seventeenth centuries are extant.)

Russia’s final emancipation from the Mongol yoke followed soon after Byzantium’s fall in the mid-fifteenth century to Ottoman Turks. Both events affected Russians deeply. Soon monk Filofei proposed that Moscow was the third Rome (after Rome proper and Constantinople) and “there will be no fourth” (cf. Zen’kovskii 1953, pp. 34–35). The idea resonated with Muscovite rulers who sought to establish themselves on the European scene. According to this doctrine, Byzantium had fallen because it departed from the true faith and Russia now inherited its mission.

Two major debates convey the atmosphere of the time. Led by the hesychast Nil Sorskii (1433–1508), the so-called “Nonpossessors” (*nestiazhateli*) condemned accumulation of wealth by monasteries and sumptuous church ritual. Their opponent Iosif Volotskii (1439–1515) argued for economically strong monasteries that could help the unfortunate and have a part in social and political affairs. Nil Sorskii was, incidentally, among the first in Russia to refer to the “natural rights” of a person—a theme that gained currency in sixteenth-century religious and political polemics there. (As peasants were being enserfed, some religious writers argued passionately—but to no avail—against slavery as a violation of Christian principles.) The other dispute was the correspondence between Ivan the Terrible and Prince Andrei Kurbskii. The latter argued in favor of a sustained role of traditional aristocracy in government. The tsar’s course, however, was to assert his absolute authority with the help of a new gentry that completely depended on his favor. Conducted with ostentatious cruelty the policy did solidify Ivan’s autocracy but at a price: By the end of the sixteenth century Russia was in the throes of a major crisis.

On Nil Sorskii's side was Maksim the Greek (1470–1556), the most remarkable intellectual in Russia during that period. Originally a humanist scholar in Florence who later took monastic vows, he was invited in 1518 from Mount Athos to Moscow to assist in translating theological works. While a controversial figure for Russian ecclesiastical authorities, Maksim was nonetheless a scholar of European stature who helped spread philosophical knowledge in Russia.

With the seventeenth century came the painful “time of troubles”: Russia's medieval complexion began to change into a modern one. By the middle of the century political and religious tensions erupted in a major schism (*raskol*), which resulted in the separation from the Church of a large group of the so-called “Old Believers.” Given the western leanings of their opponents, the energetic Patriarch Nikon and Tsar Alexis (reigned 1645–1676), the schism has been viewed as a struggle between medieval fideistic and modern rationalistic outlooks.

Early in the century Petr Mogila established a spiritual academy in Kiev, fashioned after Polish (Jesuit) models. Secular schools began to appear in Moscow and in 1678 the first institution of higher learning was founded there: the Hellene-Greek Academy. The curricula of these schools included logic, psychology, and physics. The budding academia was occupied by the controversy between the “Graecophiles” faithful to the Byzantine roots of their learning and the “Latinists” influenced by western scholasticism.

THE ENLIGHTENMENT. Inaugurated by the reforms of Peter the Great (reigned 1696–1725), the eighteenth century became the time of a rapid assimilation of western European thought. Philosophical ideas from Europe were absorbed along with progress in the arts, secular education, and science. With the establishment of the Academy of Sciences and universities philosophy attained an official secular status. From translation, publication, and dissemination of foreign literature in the beginning, Russian Enlighteners eventually moved to creating their own works.

The most urgent task for the new educated elite was the development of a secular national ideology. The medieval ideal of “Moscow the Third Rome” was being replaced with the secular ideal of the Russian Empire. The first modern Russian historian, Vasilii Tatishchev (1686–1750) saw, in the Hobbesian vein, the basis of monarchy as the agreement between the sovereign and his subjects rather than in the sovereign's divine right. He

argued, in the proto-utilitarian spirit, that “the desire of well-being is inexorable in man and stems from God.” (Zen'kovskii, p. 79). His younger fellow-historian, Prince Ivan Shcherbatov (1733–1790), sharply criticized the established church—even as his political sympathies remained on the side of landed aristocracy. Tatishchev and Shcherbatov differed on the most burning moral question of that era, the freedom of the serfs, but both saw the well-being of the nation, rather than its religious mission, as the chief goal of the state.

The ideas of the Encyclopaedists circulated widely among the educated Russian society. Empress Catherine the Great (reigned 1762–1796) was an attentive reader of Charles Montesquieu's treatise *L'esprit des lois* (The Spirit of the Laws, 1748) and maintained correspondence with Voltaire, Diderot, and d'Alambert. Her friendship with *philosophes* doubtless stimulated Voltaire's near-cult status among educated Russians. Unavoidably this interest had much to do with a facile imitation of the West but it also had its serious side. Playing the part of an enlightened monarch, Catherine undertook a relatively progressive, if halting and ultimately unfinished, governmental and legal reform.

The accelerated development of the arts and sciences in this period was epitomized by the polymath and poet Mikhail Lomonosov (1711–1765). A fisherman's son from a northern province, he became the first Russian scientist of European stature and was instrumental in promoting scientific research and higher education in his country. To him belonged the famous prophecy, in verse, that combined the zeal of an Enlightener with national pride: “The Russian land can give birth to its own Platos and quick-witted Newtons.”

Simultaneously the traditional line of Orthodox theology was carried on by Paisii Velichkovskii (1722–1794) and St. Tikhon Zadonskii (1724–1783). Velichkovskii was a spiritual elder, the type best known from Zosima, a character in Dostoevsky's novel *The Brothers Karamazov*. Arguing against the alleged sanctification of the created world in secular thought, St. Tikhon taught that the external world had to be transfigured rather than accepted on its own terms. Concentrated on righteous living and one's personal connection with the Absolute, this theology was a welcome reprieve, as Zen'kovskii notes, from the burden of justifying Russian state messianism.

A counterpoint woven of both secular rationalism and religious mysticism was created by the most remarkable philosopher of the Russian eighteenth century, the Ukrainian Grigorii Skovoroda (1722–1794). A “Nonpos-

essor” and itinerant philosopher of a Socratic mold, Skovoroda expounded an original doctrine that was inspired by ancient sources, patristic thought, and modern European philosophy. There was a Christian Neoplatonist note in his belief that man’s proper purpose was an “erotic” ascent to divinity, as well as in his self-written epitaph: “The world tried to catch me, but has failed.” His influence on the contemporary philosophical scene was, sadly, almost nonexistent; his works were not published during his lifetime and began to attract serious attention only in the nineteenth century.

A different quest for spirituality outside the Church was evident in the movement of Freemasons that started in Russia in the second third of the eighteenth century. In the 1770s there emerged among them a group led by Nikolai Novikov (1744–1818) and Johann Schwarz (1751–1784). Novikov’s contribution was mostly as an editor and publisher: from 1779 to 1792 he published almost nine hundred titles that included, aside from Russian authors, translated works of Jacob Boehme, Voltaire, John Locke, G. E. Lessing, and Novikov’s favorite, Blaise Pascal. These Freemasons combined respect for natural science with the primacy of morality over the intellect.

Alongside modern scientific realism the nascent Russian intelligentsia absorbed western utopianism. As in the West, however, utopia often served as a vehicle for social criticism. Vasilii Trediakovskii in his *Tilemakhida* (1766), a verse translation of François Fénelon’s novel *Les Aventures de Télémaque*, described the torment of monarchs in Tartarus: they looked at their own monstrous images in the “mirror of truth.” From Trediakovskii’s poem came the epigraph to Aleksandr Radishchev’s (1749–1802) *Journey from St. Petersburg to Moscow* (1790): “The monster is opulent, impudent, enormous, hundred-mouthed, and barking.” The main target of Radishchev’s moral sermon from the standpoint of natural rights was the inhumanity of the institution of serfdom. It was the most striking fruit of the Russian Enlightenment, and cost the author dearly: he was exiled to Siberia. Novikov was likewise imprisoned in St. Petersburg. Frightened by the French Revolution, the aging Empress was now perturbed by the liberties her subjects were taking.

The turn from the Enlightenment to conservatism among Russian intellectuals was vividly exemplified by the historian and writer Nikolai Karamzin (1766–1826). A proto-Westernist, he was originally attracted to Locke and Rousseau but his views evolved from a vague empiricism and tolerant sentimentalism to defending the expe-

dience, for the stability of the state, of “enslaving people rather than prematurely freeing them.” The French Revolution was the key factor in this striking change. Karamzin initially hailed it as “the triumph of reason” but then, as terror struck, condemned it as the collapse of the Enlightenment. He was among the first to give Russians a serious perspective on their own history. The poet Aleksandr Pushkin (1799–1837) compared his discovery of Russia’s past to Columbus’s discovery of America.

The Russian Enlightenment drew to a close when, after Catherine’s death, Novikov was freed only to live out the remainder of his life in obscurity, and Radishchev, a few years after his release, committed suicide. But its ideas became an integral part of Russia’s intellectual makeup. Its complex legacy contained mutually intertwined, conflicting themes, such as national identity and universal humanism, secularism and religious tradition, scientific cognition and mysticism, art and morality, theoretical quest for truth vis-à-vis social practice.

THE GOLDEN AGE. Although rooted in a long-standing cultural and spiritual tradition, Russian philosophy proper was born in the nineteenth century. As it matured, it underwent several waves of foreign influence: idealist (especially German) in the 1830s and 1840s, positivist in the 1860s, Marxist in the 1880s and 1890s—to mention only the most poignant ones. Once it appeared, each strand remained an active factor in the continuing philosophical debate. Russian mentality has been described as inclined toward extremes, and the reception of Western ideas in Russia bears out this observation: their assimilation often meant radicalization. This was true of the “Nihilists” of the 1860s who developed a cult of natural science, and later of Vladimir Lenin (1870–1924), who stripped Marxism down to its bare essentials and ruthlessly pursued his vision. Solov’ev, by contrast, strove to synthesize diverse strands into a holistic idealist vision.

The famous phenomenon of the intelligentsia arose in this century. Recruited mostly from the middle class, the new educated elite developed a degree of self-consciousness one rarely finds in its Western counterparts. The idea of its “debt to the people,” articulated in Petr Lavrov’s (1823–1900) *Istoricheskie pis’ma* (Historical letters, 1868–69), shaped the ethos of this group. From the very beginning, though, the intelligentsia was torn by internal conflict and contradictions. Its admirers saw in it the “conscience of the nation,” its critics an intolerant “monastic order” of political radicalism, and many of its members were convinced that the two were synonymous. In the meantime such major thinkers as Solov’ev, Dosto-

evsky, and Tolstoy resisted being included among its ranks. In the early twentieth century philosophers of religious orientation subjected the intelligentsia's atheist outlook to an unflattering critique. They were noisily rebuked both by radicals and liberals. Left-wing intelligentsia played a crucial part in bringing about the revolutionary turmoil of the early twentieth century—the turmoil that led to its own dispersal in the thin air of history. Originally the flag-bearer for social progress and against despotism, in the Soviet period it became an evanescent specter. Its relation to the so-called “Soviet intelligentsia” was too problematic to warrant a continuum between them.

Early developments in philosophical education were not auspicious. Organized on Wolffian principles, academic philosophy had enjoyed steady growth since the middle of the eighteenth century. From 1817 and until the mid-nineteenth century, however, it suffered from a crisis precipitated by a conservative turn in Alexander I's policy and then exacerbated by the oppressive rule of Nicolas I (reigned 1825–1855). The teaching of philosophy was abolished for long periods in gymnasias and universities. A senior official summed up the government's view of it: “Utility is doubtful, whereas harm is obvious” (Radlov, *Ocherk istorii russkoi filosofii* [Essay on the history of Russian philosophy], 1920, p. 7). To circumvent restrictions some professors taught philosophy under the guise of other disciplines, such as history or geology. Philosophical instruction continued uninterrupted, however, in religious seminaries and academies but it was not until the second half of the century that the situation of academic philosophy began to be more or less normalized. Yet even as conditions improved, Russian thought retained much of its nonacademic character. For various, mostly political, reasons prominent thinkers—be it Aleksandr Herzen (1812–1870), Solov'ev, or Nikolai Chernyshevskii (1828–1889)—worked outside universities.

In the 1820s the first philosophical circle appeared; its members called themselves by the Russian equivalent of *philosophes—liubomudry*, “lovers of wisdom.” The group's leader, Prince Vladimir Odoevskii (1804–1869), presented a Schellingian view of Russia's future in his utopian dialogue-novel *Russian Nights* (1844) in which he gave a modern version of Russian messianism. History moved, he rhapsodized, toward “a holy triunity of faith, science, and art.” Anticipating Dostoevsky, he claimed that Russia was destined to accomplish this universal synthesis because of her “all-embracing multifaceted spirit.”

Such optimism, however, was in sharp contrast to the somber skepticism of Petr Chaadaev's (1794–1856) *Philo-*

sophical Letters. Chaadaev saw the West as the ideal of civilization; all other societies were, in his opinion, mere approximations to it, with Russia falling outside the category altogether. Chaadaev's bitterness was cast against the background of two recent events: Russia's victory over Napoleon in 1812 that encouraged hopes for the nation's greatness, and the crushing defeat of the 1825 Decembrists's uprising that extinguished hopes for reform and liberty. He was inspired in large part by Joseph de Maistre and Friedrich Schelling. He later fine-tuned his position to argue that Russia was called upon to resolve the contradictions that still plagued the West. The evolution of Chaadaev's views became typical for Westernists: from adulation of the West to disillusionment to seeing Russia's potential in her backwardness. The conviction that Russia was a “virgin soil” whose lagging behind could be turned to advantage as “the possibility of choice” became the cornerstone of Westernist constructions from Herzen to Vladimir Lenin (1870–1924). Chaadaev's caustic but profound outburst brought into existence two opposite trends, the Westernists and Slavophiles, whose mutual rivalry has since shaped, and continues to shape, the evolution of Russian thought.

Because of their intertwined destinies “Slavophiles” and “Westernists” come close to being the worst misnomers in the history of Russian thought. Both groups were deeply dissatisfied with the current conditions in Russia. Contrary to the xenophobic connotation of their name, many Slavophiles respected European learning and culture and kept abreast of recent Western philosophical thought. For their critique of the West they often borrowed ammunition from the West itself. Conversely, the Westernists' professed cause was to save Russia, and many of them even believed, such as Herzen, that Russia held the key to saving the West from the West's own woes. For both, the goal of “enlightening” Russia was of paramount importance, although they were divided on the possibility of “national science.” Slavophiles defended the idea (without defining it clearly), whereas Westernists rejected it in favor of universal rationality.

And yet their differences were not trivial. Slavophiles believed that, enviably advanced as it was, Europe had come to an impasse and Russia had to avoid a similar fate. The West's original sin, according to Slavophilism, consisted in the rationalistic tendency of Roman Catholicism that was codified in the *filioque*; that is, the dogma that the Holy Spirit proceeded from *both* the Father *and* the Son. Both early Slavophiles, such as Aleksei Khomiakov (1804–1860) or Ivan Kireevskii (1806–1856), and their later followers, such as Sergei Bulgakov (1871–1944) or

Nikolai Losskii (1870–1965), accused Catholic theology of replacing the mystery of the Holy Trinity with a hierarchical scheme in which the Holy Ghost was subordinated to the other two persons. This eventually led, via scholasticism, to Protestantism and thence to modern secularism. The decline of the authority of the Church in turn weakened, Slavophiles believed, the foundations of communal life and created the West's atomistic individualism. Russia, they claimed, could offer an alternative because its culture still contained the original wholesome elements, unspoiled by the westernization of the previous two centuries.

Against rationalism in epistemology the Russian mind could offer, Kireevskii argued, the ideal of integral knowledge in which rational thinking and divine revelation would be properly balanced. Against individualism in social philosophy it could offer *sobornost'*—the concept that amalgamates “togetherness” with “conciliarism” (from “church council”) and projects the ideal of an humanity united by love and faith, where the freedom of the individual is in harmony with the common cause. Khomiakov found its manifestation in the Orthodox Church and Konstantin Aksakov (1817–1860) in the Russian village commune. Russia's historical task was understood as universal, although it remained unclear how other nations, who had their own traditions, were supposed to accept Eastern Orthodoxy. Slavophiles' concern, however, was to outline Russia's potential place in the “family of nations” rather than to develop a specific strategy for attaining it. The mankind of the future was perceived, in Aksakov's terms, as a “choral person”—the notion that in the twentieth century was assimilated by Lev Karsavin (1882–1952) into his doctrine of humanity as a “symphonic person.”

Westernists, on the contrary, insisted that Russia needed to join advanced European nations in pursuing economic, social, and political progress. Where Slavophiles envisioned *sobornost'*, Westernists insisted on the legal rights of the individual. If Slavophiles found pristine purity in pre-Petrine Russia, Westernists blamed the country's slow progress on xenophobic medieval Russian tsardom. Their sharpest difference from Slavophiles, however, consisted in their hostility toward religion. In Herzen's words, there was an “ecclesiastic wall” between him and his opponents. The common limitation of both was their utopianism: One idealized Russia's past and the other, the West's present. Furthermore, for neither of them philosophy had independent value but was merely an instrument for achieving goals other than knowledge and understanding.

The reception of Schelling and Hegel casts a helpful light on the manner in which philosophy's tasks were conceived. Schelling's philosophy enjoyed a warmer reception—at least in the religious segment of Russian thought. In fact, there is some truth to Arsenii Gulyga's (1921–1996) remark that “Russian philosophy is a Schellingian.” With Hegel Russians tended to distance themselves, even as they respectfully learned from him; in Schelling they found a kindred spirit. The view of the world as an organic whole has had more followers and fewer detractors in Russia than in the West; it retains importance there to this day. Schelling's doctrine of intellectual intuition proved particularly attractive to Russian thinkers. From Odoevskii to Solov'ev they embraced the notion of an immediate meeting of consciousness with both inner and outer reality; in the twentieth century it inspired a whole intuitivist school. Chaadaev was deeply affected by Schelling's philosophy of revelation; Kireevskii and Solov'ev, by his epistemology; Odoevskii and Bulgakov, by his *Naturphilosophie*; and Aleksei Losev (1893–1988), by his aesthetics and philosophy of myth. Many of them found in Schelling's thought inspiration for viewing art and religion as (extrarational) sources of rational thinking.

Russian liberal thought was, by contrast, at its inception primarily Hegelian. Vissarion Belinskii's (1811–1848) and especially Herzen's engagement with Hegel's philosophy were typical. Both embraced Hegelianism in the beginning but then rejected what they perceived as its abstract universalism. Belinskii, on the one hand, got most of his Hegel via Mikhail Bakunin (1820–1900) who at the time was an overenthusiastic Hegelian. Herzen, on the other hand, attentively studied Hegel's writings firsthand. The result was, however, more or less similar. “(Hegelian) reason does not know,” Herzen impugned, “*this* person but only the necessity of a person in general ...” (*Zen'kovskii*, pp. 285–6). The main point of Herzen's dissatisfaction was the same as Karl Marx's: life is not merely about thinking, he insisted, but chiefly about acting in the world. Virtually all Russian philosophers turned away from Hegel upon initial acquaintance. Those consumed by revolutionary causes, such as Bakunin, blamed him for excessive contemplativeness, whereas Slavophiles and religious philosophers rejected his doctrine of a rationally cognizable absolute. Various parts of Hegel's system were adopted but only the rarest exceptions, such as Boris Chicherin (1828–1904), accepted its essential core, the doctrine of the absolute concept. Characteristically, Herzen found in Hegel's dialectic “the algebra of revolution”—a description that was later eagerly endorsed by Lenin. This appropriation

epitomized the political pragmatism that was imposed on the German philosopher's speculative method.

Philosophers' concerns for "the concrete person" were nourished by the burgeoning Russian realist literature that paraded, in an intensely empathetic light, a series of characters whose suffering was a condemnation of a social order in which human dignity was out of place. Conversely, Russian thinkers frequently offered their insights in literary form. In fact, the most burning of the "cursed questions" that preoccupied the intelligentsia throughout its existence were articulated as titles of literary works: Herzen's 1847 novel *Who Is to Blame?* and Nikolai Chernyshevsky's (1828–1889) 1863 socialist utopia *What Is to Be Done?* The latter query proved particularly haunting: Leo Tolstoy in 1883 and Lenin in 1902 each wrote a work bearing similar titles.

Hegel and Schelling were soon replaced by Ludwig Feuerbach and Left Hegelians as socialist ideas were spreading among educated Russians. In the 1860s materialism propounded by Ludwig Büchner and others was added to the mix; it was embraced by the so-called "Nihilists" whose leading figures were Dmitrii Pisarev (1840–1868), Nikolai Dobroliubov (1836–1861), and Chernyshevskii. Pisarev's crude materialism, however, was not so much a philosophical position as a propagandistic means of destabilizing old religious and social values. Calculated to outrage, his maxim that "boots are more valuable than Shakespeare" was, in fact, a call to social activism as opposed to the aesthetic hedonism of the leisure classes. It was also a message about the utility of science and technology; that is, the business of the newly emerging class of physicians and engineers, contrasted with the aristocratic art of the previous era. The most articulate thinker of the "Nihilist" camp, Chernyshevskii, by contrast, argued for genuine art that would be a life-transforming praxis rather than idle entertainment. The rise of Nihilism marked the radicalization of Herzen's intellectually broad and humane liberalism, and the beginning of the latter's transfiguration into fanatical revolutionism.

In the late 1860s and 1870s the earlier materialism was absorbed into the broad social, cultural, and ideological movement called "Populism" (*narodnichestvo*). Its intellectual leaders, Lavrov and Nikolai Mikhailovskii (1842–1904), combined positivist epistemology and materialist metaphysics with an evolutionist view of history. The Populists' goal was socialism in Russia, on the basis of the village commune. Their views about both the goal and the ways of achieving it, however, varied from the anarchism of Bakunin and Petr Kropotkin

(1842–1921) to the conspiratorial terrorism (with a Marxist tinge) of Petr Tkachev (1844–1886). The Populists' main philosophical difficulty consisted in reconciling the individual's agency with positivist determinism. Like their materialist predecessors, however, these thinkers did not embrace a particular philosophy of nature or history for its intellectual merits but were interested primarily in using it for social change. It was Mikhailovskii who pointed out, memorably, the conflation of "truth" and "justice" in the Russian word *pravda* that has since come to signify one of the most pervasive features of the Russian philosophical mindset. It was also Mikhailovskii whose "subjective method" in sociology was intended to enhance the ability of "critically thinking individuals," as Lavrov called them, to influence the course of history. Populism later evolved into the political party of Socialist Revolutionaries, the Bolsheviks' most powerful left-wing rival, and its ideas continued to exercise their influence well beyond its final collapse in the 1920s.

Less influential was the moderate liberal thought of such thinkers as Konstantin Kavelin (1818–1885) and Boris Chicherin (1828–1904) who defended, from an Hegelian position, the ideals of the law-governed state in political theory and the universal "higher synthesis" of religion and philosophy in epistemology. As the earlier Westernism was radicalized, so too the original, rather moderate Slavophilism was producing its own increasingly radical offshoots. Konstantin Leont'ev (1831–1891) offered a scathing critique, on aesthetic grounds, of contemporary Western society. Unlike Friedrich Nietzsche with whom he is frequently compared, Leont'ev ended not with a call for a proud Overman, but with a return to an ascetic Orthodoxy. Nikolai Danilevskii's (1822–1885) theory of "cultural-historical types" advanced a cyclical model of history in which the tired Romano-Germanic civilization was about to yield its place to a younger Pan-Slav one. Danilevskii's ideas had an impact on the "back-to-the-soil" group of authors (*pochvenniki* from *pochva*, the Russian for "soil"), whom Dostoevsky lent his not insignificant authority.

Dostoevsky was, incidentally, one of the first Russian thinkers who had a marked influence on Western philosophy. His explorations of the religious, moral, and psychological dimensions of the human condition made a deep impression on both contemporaries such as Nietzsche and later figures such as Albert Camus. Inside Russia Dostoevsky's ideas reverberated in the religious-philosophical school of the early twentieth century.

The more liberal patrimony of Slavophilism, however, was cultivated by Russia's first truly great philosopher Solov'ëv. Solov'ëv's philosophy was an impressive attempt to fuse together positivism, idealism, and mysticism. His early critique of positivism evolved into the assimilation of Auguste Comte's ideas into his own view of history as divine will unfolding toward "free theocracy." Comte's *Grand Être* was likewise absorbed, along with Gnostic, Cabalistic, Eastern Orthodox, and German Romantic ideas, into Solov'ëv's neoplatonist metaphysics of Sophia Divine Wisdom. Later Solov'ëv performed a similar operation on Chernyshevskii's positivist aesthetics by interpreting it in the light of his own doctrine of art as theurgy: that is, humanity's continuation of divine creation. Yet his syntheses were not eclectic but rested on a broad conceptual foundation and formed a more or less coherent system—the first created by a Russian philosopher. With his more eager, ecumenical acceptance of the West Solov'ëv modified earlier Slavophilism and worked to reconcile it with Westernism. Above all, however, his most lasting contribution consisted in the apologia of philosophical idealism. Solov'ëv and Dostoevsky remained lonely voices among the intelligentsia during their lifetime but by the time of Solov'ëv's death a reaction had already begun among a new generation of philosophers against secular ideologies and in favor of a serious engagement with religion.

While the rebirth of philosophical idealism was only dawning, however, its antipode was vigorously gaining ground. Marxism was known in Russia since the late 1840s but in its early stages it was only one among several currents of socialist thought. Nevertheless, it soon attracted significant interest: In 1869 Bakunin published (abroad) his translation of the *Communist Manifesto*, and three years later Russian became the first foreign language in which the first volume of *Das Kapital* appeared. By the end of the century Marxism became the most influential political doctrine among the intelligentsia. It established itself in competition with earlier socialist theories, primarily Populism. In contrast to Populists who wished Russia to avoid capitalism and leap, via village commune, directly into socialism, Marxists viewed capitalism as a stepping stone to socialist revolution. The abolition of serfdom in 1861 by Alexander II gave a strong impetus for the development of capitalist enterprise and, as the number of factory workers grew, socialist theorists began to pin their hopes on the new class. The key figure in the transition from Populism to Marxism was Georgii Plekhanov (1856–1918). His main concern seems to have been to elaborate a philosophical system based on Marxist precepts, while guarding the original doctrine against

misinterpretation and revisions. A significant feature of Plekhanov's reception of Marx's ideas was their refraction through Frederic Engels's work. Russian Marxists did not always take care to distinguish Marx from Engels and often argued—in fact, often they simply assumed—the unity of the two founders' respective positions.

In the last quarter of the century Russian academic philosophy finally became the key factor on the philosophical scene. The generation of Solov'ëv and Mikhailovskii was receding into the past and most leading thinkers now taught at universities. Chicherin gradually developed his own system with an emphasis on the philosophy of right and of history. A Leibnizian revival was evident in the trend started by Aleksei Kozlov (1831–1931) that stimulated the development of personalism in Russian thought. The latter had an exceptionally far-reaching impact on such thinkers as Berdyaev, Losskii, and Lev Shestov (1866–1938). This was also the time when Kant's presence in Russian thought finally came to match that of Schelling and Hegel. The leading neo-Kantian Aleksandr Vvedenskii (1856–1925) concentrated on logic and philosophical psychology. Advocated by a number of scientists and philosophers, such as Vladimir Vernadskii (1863–1945) and especially Vladimir Lesevich (1837–1905), neopositivist thought was another major current in academic philosophy. It was concerned almost exclusively with the philosophy of science and empirical epistemology. Vernadskii's ideas later played an important part in what became known as Russian cosmism. The original tenets of this loosely defined trend were formulated by the (nonacademic) Nikolai Fedorov (1828–1903) whose eccentric hybrid of positivism and Christian eschatology aimed at the physical resurrection of all past generations.

THE SILVER AGE. The flourishing of the arts and philosophy, roughly, from 1890 to 1925 is often referred to as the "Silver Age." It was marked by the rise of Symbolist poetry, modernist music, avant-garde art, and a general invigoration of cultural life. The Silver Age unfolded against the background of growing capitalism and a relative liberalization of political life, punctuated by wars and revolutionary turmoil. New developments in the arts underscored expectations of tectonic shifts in political history. The theme of an impending catastrophe—hailed as a purifying storm by some and feared as a fatal calamity by others—haunted artists and philosophers alike. Russia's humiliating defeat in a war with Japan precipitated the first, abortive popular uprising in 1905. The tsarist government agreed to halfhearted parliamentary reforms but they were undermined by the outbreak of

World War I in 1914 and then annulled altogether by the Bolshevik revolution of October 1917.

Russian philosophy matured during this period. From the 1890s on government restrictions were loosening and in the early 1900s the autonomy of universities finally began to materialize. In 1889 the first professional philosophical journal, *Voprosy filosofii i psikhologii* (Questions of philosophy and psychology) was founded, followed in the first decade of the new century by several other publications specializing in philosophy. In 1897 the St. Petersburg University Philosophical Society was established and a few years later it was joined by the Religious-Philosophical Society in Memory of Vladimir Solov'ëv in Moscow and the Religious-Philosophical Society in St. Petersburg.

Contacts with European philosophy reached a high point. Russian philosophy was now fully integrated, if still as a minor partner, into the European philosophical culture. The most recent developments in Western thought were quickly assimilated by Russian thinkers; empirio-criticism and phenomenology were only the more notable among such new trends. The growing influence of Kant was mentioned above. Nietzsche's impact on the Russian thought of this period was profound and pervasive.

Two opposite, unequal trends dominated the scene during this time: Marxism and religious philosophy. The former was philosophically unimpressive but politically influential, whereas the latter, on the contrary, was politically insignificant but philosophically fertile. Their complex mutual interactions, ranging from antagonism to fusion, were the manifestations of a dynamic and visionary rather than rigorous *Zeitgeist*. Scientific positivism and political liberalism also continued, adding to the increasingly vibrant philosophical life.

The brand of Marxism that emerged as a result of Plekhanov's efforts and was now endorsed in the main by Lenin included the following basic components. It was founded on a materialist ontology; that is, the view that matter constitutes the source of all existence. Materialism was enhanced by a positivist epistemology that held modern science to be the only legitimate source of knowledge. Marxism considered itself a true—in fact, the only true—doctrine *because* it was a modern scientific theory. Its next key component, historical materialism, was the result of synthesizing the first two with Hegel's philosophy of history. And finally the whole was held together by dialectical materialism, also a permutation of Hegelian dialectics adapted to fit materialism and positivism. (Needless to say both Hegel's philosophy of history and

his dialectics were drastically deformed in these hybrids.) Materialist orientation also dictated that all social and political phenomena be viewed as determined by a society's economic base. The latter developed, according to the theory, over periods of gradually accumulating quantitative changes leading up to abrupt moments of revolutionary qualitative change. The result was the view that history was logical progress from one socioeconomic formation to another, culminating in communism as the most rational system. There was no room for divine authority in this picture; militant atheism was an indelible feature of Russian Marxism. In an apparent contradiction to its own economic determinism, the key factor in the "inevitable" socialist revolution was Marxism itself as a doctrine of "scientific socialism." Further, despite being the most revolutionary class, the proletariat had to be educated; as Lenin argued, "scientific socialism" had to be instilled in its consciousness.

In ethics universal moral values were rejected as products of "abstract bourgeois humanism" in favor of the view that all values were determined by class interest. The corollary was that, as the revolutionary vanguard of society, the proletariat held values that were superior to those of any other class. In aesthetics a similarly class-based criterion was adopted: judgment about art was determined by which class interest it promoted. Leo Tolstoy's oeuvre, for example, was famously described by Lenin as "the mirror of the Russian revolution." These principles received a less stark complexion once they were combined with a dialectical view of history according to which new eras partially reject but also partially absorb the achievements of previous ones. Thus the proletariat was supposed to have inherited the best that world civilization had developed prior to socialist revolution. But the ultimate authority on all issues belonged to the proletariat's own vanguard, the Communist Party. Likewise Lenin's unabashedly utilitarian, ideological aesthetic eventually replaced Plekhanov's earlier, more nuanced attitude as the official "partisan principle" in evaluating art.

There soon evolved two currents in Russian Marxism: radical and moderate. Lenin and his fellow Bolsheviks (the term "Bolshevik" literally means "a member of the majority") promoted the former, whereas the so-called "legal Marxists" that included Petr Struve (1870–1944), Berdyaev, and Bulgakov, advocated the latter. The radical trend absorbed from extremists such as Tkachev revolutionary voluntarism and justification of terror as a means of political change.

The main controversies that divided these currents had to do with whether Russia could bypass an extensive phase of capitalism and bourgeois democracy, and proceed directly to a socialist revolution. Lenin answered in a resounding affirmative, whereas his opponents, including Plekhanov, favored a less precipitous path. They feared that the dictatorship of the proletariat, which the Bolsheviks envisioned as the key instrument of transition from a semifeudal to socialist society, would be as oppressive as the tsarist regime. The question of eschewing a prolonged capitalist phase was also bound up with whether Russia could pursue the socialist path alone among nations. In classical Marxism progress toward socialism had been envisioned as an international process because capitalism was itself an international system, too entrenched for the proletariat of one country to overpower it. Russian Marxists split on the issue: The moderate wing laid stress on international cooperation and advocated waiting for ripe conditions in advanced European nations, whereas the radical wing insisted that it was possible to establish socialism in one country.

The main philosophical difficulty for Marxists stemmed from the materialist foundation of their doctrine and consisted in explaining how purely physical, unconscious matter could generate movement and, ultimately, consciousness. The argument that matter evolved in accordance with the laws of nature only raised questions about the origin of these laws themselves. Plekhanov and Lenin asserted that science disclosed what matter was but this claim lost its persuasiveness as new conceptions of matter were developed in physics and the hypothetical nature of these views became increasingly apparent. Lenin's statement that "matter is objective reality given us in sensations" was vague enough to accommodate idealism and thus created more problems than it solved. Similar problems haunted Marxist ethics. The critics of the dogmatic trend, such as Struve, complained that class interest did not provide a firm foundation for morality and, further, dissolved individual agency in socioeconomic forces. The dismissal of art as an activity with a distinct purpose was also problematic. Nor did philosophy itself fare better. "From Marx's and Engels' point of view," wrote Lenin in his essay "The Economic Meaning of Populism" (1894), "philosophy has no right to independent existence and its subject-matter divides itself [literally 'disintegrates,' *raspadaetsia*] among several branches of positive science."

In evaluating its claims, however, it is critical to realize that Russian Marxism was first and foremost a doctrine of political action. Its logic, philosophy of history,

social philosophy, epistemology, and even materialist ontology were adopted under the pressure of a specific sociopolitical ideal. It was the ideal of a strictly secular, modern society aimed at assuring the fullest realization of the immanent human potential by rationalizing the production and distribution of material wealth. The "superstructure" was to align itself with, and serve the achievement of, this goal. Hence Lenin's relentless defense of materialism, insistence on the scientific nature of Marxism, and uncompromising atheism. In Lenin's thought Russian Marxism's ideological pragmatism reached its apogee. Scant and unimpressive at best, his philosophical writings were all occasioned by topical debates and aimed at ensuring the resolve of the Bolshevik party. The motivation for his most extensive philosophical work, *Materializm i empiriokrititsizm* (Materialism and empiriocriticism, 1909), for example, was to rein in his comrades Lunacharskii and Aleksandr Bogdanov (1873–1928) who had strayed into "God-building" and "empiriomonism." The only exception was Lenin's *Filosofskie tetradi* (Philosophical notebooks, 1914) in which a more serious engagement with Hegel was evident, but these were private ruminations published only posthumously. Materialism and dialectics were meaningless for Lenin unless they were employed for the communist cause. "Materialism," he wrote, "includes partisanship (*partiinnost'*)."
(*Collected Works*, Vol. 1, 1960, p. 401).

The moderate branch of Russian Marxism was more in earnest about resolving the philosophical difficulties of the doctrine but attempted solutions led to revisions of its original materialist, positivist, and deterministic tenets. The "legal Marxists" Struve, Berdyaev, and Bulgakov eventually abandoned orthodox Marxism in favor of philosophical idealism.

This was a sign of the opposite trend that became evident in the emergence of neo-Kantianism and especially religious idealism. The return to Kant was chiefly a development in academic philosophy, whereas the turn to religion swept along academics, independent thinkers, and artists. In later literature the appearance of a group of philosophers who drew inspiration from religion was described as a "religious-philosophical renaissance." The writer Dmitrii Merezhkovskii's (1865–1941) quest for a "new religious consciousness" was a more popular manifestation of this trend. Merezhkovskii initiated Religious-Philosophical Meetings in 1901–1903 as an attempt at a rapprochement between the church and the intelligentsia. The participating sides were ill at ease with each other and after Vasilii Rozanov's (1856–1919) character-

istically shocking call upon the clergy to sanctify physical sex the meetings were stopped on government's orders.

Three publications mark the evolution of this trend in the first two decades of the century. The 1902 anthology *Problemy idealizma* (Problems of idealism) was an initial attempt to revive idealism as a viable contemporary philosophical position, followed by the *Vekhi* (Landmarks, 1909), a cutting critique of the intelligentsia's ideological dogmatism, atheism, and social isolation, and, finally, by *Iz glubiny* (De profundis, 1918), a reaction to the Bolshevik revolution as an anti-Christian act prepared by the spiritual, cultural, and moral crisis of the previous two decades. (This indictment was echoed by Rozanov who called the Revolution "the apocalypse of our time.")

The crucial problem that these thinkers confronted was the reconciliation of philosophy with religion. The impulse to embrace religion came as a result of recoiling from materialism and positivism. Many religious philosophers began as Marxists in their younger years and then underwent an idealist conversion. But an attempt to reconcile religion and philosophy led to the choice between fideism and rationalism. Like their predecessors, Slavophiles and Solov'ev, Russian religious philosophers ultimately leaned toward the former. Ernest Radlov (1854–1928) even claimed in his 1920 *Ocherk istorii russkoi filosofii* (A survey of the history of Russian philosophy) that the tendency among Russian thinkers toward a mystical solution of ethical and epistemological questions was a "national trait." A closely related task that these philosophers pursued was defense of idealism. In many cases such defense involved rethinking the relation between ideas and empirical reality and resulted in a number of constructs: the "concrete idealism" of Sergei Trubetskoi (1862–1905), "ideal-realism" of Losskii, and "mystical realism" of Berdyaev. The "abstract" thought of German Idealism often served as a contrasting foil for these attempts to bring idealism closer to life.

At the same time the religious-philosophical school argued for a secular culture and philosophy informed by the Orthodox faith—domains that had been neglected, in their opinion, by the Russian Orthodox Church. Florenskii's 1914 classic *Stolp i utverzhdienie istiny* (The pillar and ground of truth) was perhaps the most monumental attempt to fuse together a modernist philosophical and aesthetic sensibility with Orthodox faith. The most important sources of inspiration for them included the thought of the early Slavophiles and especially of Vladimir Solov'ev. In epistemology they questioned both extreme rationalism and extreme fideism but their atti-

tudes varied widely. In method their approaches ranged from Losskii's strict adherence to formal logic to Semen Frank's (1877–1950) moderate dialectics to Berdyaev's aphoristic impressionism. In metaphysics many of them followed and further developed Solov'ev's doctrines of all-unity and Sophia Divine Wisdom. Their views on philosophy of history encompassed Florenskii's admiration of the Middle Ages, at one pole, and Berdyaev's progressivist Christian socialism, at the other. In political philosophy they were likewise diverse: Ivan Il'in (1883–1954) rigidly advocated monarchism, whereas Viacheslav Ivanov (1866–1949) vaguely evoked mystical anarchism. The only thing that united them was the conviction that modern secularism had exhausted itself and the reinvigoration of philosophy and culture in general was to be sought in a union with religion.

A particularly notable contribution by this group was their writings on the history of Russian philosophy. Evgenii Trubetskoi's (1863–1920) classic study on Solov'ev, Berdyaev's essay on Khomiakov, Gustav Shpet's (1879–1937) hypercritical survey, and Radlov's work mentioned above were part of this self-examination. A special place in this literature belongs to works on the "Russian Idea." Rooted in the writings of Dostoevsky and Solov'ev, this trope grew into a body of literature created by several generations of philosophers. On the broadest level, it referred to the unique Russian type of consciousness, culture, historical destiny, and place among the peoples of the world. After the Revolution this tradition was further elaborated in Eurasianism and culminated in Berdyaev's classic *Russkaia ideia* (The Russian idea, 1946). It eventually reemerged in post-Soviet thought where it took on still other interpretive hues.

Along with metaphysical, epistemological, and political issues, an exceptionally preeminent concern for this group was art, which they viewed as a conduit for religious enlightenment. Evgenii Trubetskoi, Florenskii, Bulgakov, and Berdyaev all dedicated to art some of the most inspired pages of their philosophical prose. Their insights into icon-painting (which Trubetskoi described as "theology in color"), liturgy (which Florenskii interpreted as the Orthodox *Gesamtkunstwerk*), and artistic creativity in general remain to this day exemplary in their subtlety and depth.

Even more than before Russian philosophy evolved during this time in an intense dialogue with the arts. The Russian avant-garde was often inspired by, and inspired in turn, the volatile mix of philosophical ideas. Among artistic movements Symbolism stood out, both in terms of its artistic influence and engagement with philosophy.

Poets Andrei Belyi (1880–1934), Aleksandr Blok (1880–1921), and especially Ivanov keenly explored the philosophical dimensions of their art. Symbolists came to the view, rooted in Romanticism and Solov'ev's theurgy, that art provided access to the "more real" plane of being and was a path toward spiritual or even cosmic transfiguration. Both philosophers and artists were fascinated with the limits of art. A wide array of artistic movements was driven by a desire to break down the barrier between art and life raised by Kantian disinterested aesthetic contemplation. The pivotal event of this period, the Bolshevik Revolution, did not initially stop this feverish activity but marked a watershed that inaugurated a new phase in the history of Russian philosophy.

THE SOVIET PERIOD. Two major processes were under way in the 1920s: the decline of the Silver Age and the rise of Soviet ideology. The new government sought a total submission of philosophy to state ideology and the means by which this was assured ranged from administrative pressure to exile to physical annihilation of dissenting thinkers. Berdyaev's Free Academy of Spiritual Culture and the Free Philosophical Association founded by Radlov, Losskii, and others in St. Petersburg were short-lived attempts to continue prerevolutionary activity. Philosophers associated with both were expelled from the country in 1922 among a large number of thinkers and scholars unsympathetic to the Bolshevik regime. In 1921 the teaching of non-Marxist philosophy was banned and in 1923 philosophy was replaced by dialectical materialism in higher education.

The tasks of Soviet philosophy consisted in "developing" Lenin's patrimony (which meant strictly adhering to its key tenets), combating domestic and foreign "bourgeois idealism," justifying the Party's political decisions, and supplying methodology to the sciences. Formulated even before Soviet philosophy as such was in existence, these tasks remained unchanged throughout the Soviet period. As state ideology Soviet Marxism was based on the Plekhanov-Lenin interpretation of Marx and Engels's views that was soon branded "Marxism-Leninism."

The debate during the 1920s between the so-called "mechanists," such as Nikolai Bukharin (1888–1937), and "dialecticians," led by Abram Deborin (1881–1964), was "resolved" by a ukase from the Communist Party. The episode served to solidify the typical Soviet way of "philosophizing": The last appeal was not to logic and reason, but to the recorded opinion of the "classics of Marxism-Leninism." The highest authority in interpreting the latter belonged, in turn, to the leadership of the Party. The

debate highlighted the paradox encapsulated in the expression "Soviet philosophy." On the one hand, Soviet ideology was based on a *philosophical* theory; on the other hand, this theory was *dogmatically* accepted as the final word in all ultimate matters. As a result, Soviet philosophy was implicitly burdened with the impossible task of reconciling the internal contradictions of Marxism—but only by appeal to Marxist principles themselves. The basic contradiction of the doctrine consisted in the fact that it insisted on the ontological primacy of matter over spirit but at the same time wished to be a theory (i.e., spirit) that changed the material world.

The untenable nature of this exercise did not escape contemporaries. Losev, whose eight volumes published between 1927 and 1930 were the swan song of the philosophical Silver Age, publicly called dialectical materialism a crying absurdity and challenged Soviet Marxists to acknowledge that their professed scientific rationalism was at bottom as mythological as any theology. His was a lonely voice, however, and it was silenced forthwith by an arrest, confinement at labor camps, and a ban on publishing upon release.

The repressions of the 1930s were the lowest point in the history of philosophy in Russia. The pre-Soviet intelligentsia was either intimidated or physically annihilated. In 1937 Florenskii and Shpet were executed in the Gulag. Russia was being purged of its philosophy. To train the new cadre was the task of the recently established Institute of Philosophy in Moscow. There were some attempts to simulate philosophical activity but they were crude and tendentious beyond redemption. Stalin's chapter on dialectical materialism in the 1938 *Kratkii kurs istorii KPSS* (History of the Communist Party of the Soviet Union [Bolsheviks]; short course) was not a philosophical work; it merely sealed the reduction of philosophy to ideological indoctrination for which epistemological or logical concerns were irrelevant. During Stalin's time the voluntaristic (i.e., ultimately terrorist) component in Russian Marxism overshadowed its other aspects. The three-volume *Istoriia filosofii* (History of philosophy) that appeared in 1940 brought to a simplistic pitch a tradition of interpretation established already by Lenin. The entire history of philosophy was presented as a struggle between "progressive" materialism and "reactionary" idealism. In 1947 Georgii Aleksandrov (1908–1961) published his *Istoriia zapadnoevropeiskoi filosofii* (History of Western-European Philosophy), based on similar principles of analysis.

This *History* figured prominently in Andrei Zhdanov's speech the same year, in which he announced

to the new generation of philosophers the Party's orders to be "more creative." Zhdanov's admonitions had a certain positive effect: For the first time since the 1920s the history of Russian philosophy, for example, became a legitimate subject. To bolster Marxism-Leninism's pedigree Soviet authors ingeniously discovered materialism in the ideas of Russian thinkers. Radishchev, Herzen, and Belinskii were recruited into the ranks of Lenin's precursors. Pisarev, Dobroliubov, and Chernyshevskii were, somewhat more justifiably, painted as "revolutionary democrats" and their materialism as a spontaneous discovery of truth prefiguring "scientific socialism." Tendentious as it was, this work was a step forward from the previous period of forced oblivion.

In the meantime philosophers of non-Soviet orientation continued to write privately "into the drawer." After his release from the camps Losev wrote treatises on ancient mythology and aesthetics, as well as philosophical prose. His fellow-survivor from the Silver Age Mikhail Bakhtin (1895–1975) worked on his theories of literature and culture; and Vernadskii developed his doctrine of the noosphere. The ideas of these authors became known only decades later when their works contributed to the intellectual ferment of the 1960s–1980s.

After Stalin's death in 1953 and especially after Nikita Khrushchev's 1956 official condemnation of Stalin's "personality cult" a "thaw" began during which ideological constraints on philosophy were gradually loosened. Khrushchev made an attempt to boost slipping enthusiasm for communism by adopting a new program for the Party but the effect of its exorbitant promises was cynicism rather than renewed optimism. Leonid Brezhnev and the new generation of leaders who came to replace Khrushchev were even less capable of reviving the decaying ideology and from the late 1960s a period of ever deepening disillusionment set in that eventually led to the fall of the Soviet Union in 1991.

In the 1950s and 1960s Soviet philosophy became an increasingly complex agglomeration of disciplines and approaches. The list of permissible themes gradually expanded. The precept, for example, of sacrificing the individual to the needs of the socialist state began to be revised as the human person was cautiously explored as a philosophical subject. Debates on the nature of philosophy ended, thankfully, in an ambiguity as to whether it was a science, theory of action, or world view. The discussion of materialism and dialectics likewise led to a number of diverging positions that included even disagreement with Lenin. Restrictions were still in place and it was impossible to challenge official orthodoxy directly

but attempts to solve its problems objectively tended to water down and sometimes even to dissolve its basic precepts. Some philosophers sought refuge from ideology in such relatively neutral areas as philosophy of science, logic, and other formal pursuits that became possible since the late 1940s. Formal logic was somewhat buttressed by the growing prestige of science and technology. Although difficult and limited, exchanges with the outside world gradually expanded through translations, visits, and conferences. Conversely, the work of some Soviet philosophers, such as the semiotician Iurii Lotman (1922–1993) and his colleagues in the so-called "Moscow-Tartu School," found international recognition.

From the mid-1950s on some pre-Stalin figures reemerged. In Losev's prodigious output from 1953 to the time of his death in 1988 the partial truths of Marxism found their place among the broader principles of a phenomenologically modified Christian neoplatonism. Bakhtin's dialogic theories of culture, literature, and the (moral) self similarly rested on philosophical foundations that were sufficiently deep not to be perverted by adaptation to Soviet censorship. Unlike Losev who remained virtually unknown outside Russia, Bakhtin has become a towering presence in the western humanities.

The reappearance of these and other authors demonstrated that communism had not destroyed the continuity of the Russian intellectual tradition. This was largely due to Russian classical literature that remained even in the worst of times the backbone of all humanistic learning and education in Russia. The other key factor was the "Aesopian" writing, stemming from nineteenth-century polemics, by which philosophers masked (transparently enough for the reader to grasp) the true principles behind their critique of philosophy, art, religion, and culture. Losev delivered, for example a blistering critique of modernity in his *Estetika Vozrozhdeniia* (The aesthetics of the renaissance, 1978) that was tacitly based on an Eastern Orthodox view. A similar line of thought was pursued by younger philosophers such as Piama Gaidenko (b. 1934), Iurii Davydov (b. 1929), and Sergei Averintsev (1937–2004).

Characteristically, the most gifted among the newer generation of philosophers had to abandon classical Marxist materialism. Eval'd Il'nikov (1924–1979) and Merab Mamardashvili (1930–1990) exemplified opposing positions on the dialectical method, almost Hegelian in Il'nikov's case and almost openly neo-Kantian in Mamardashvili's. Yet another, mathematical-formalist, argument against the officially accepted dialectical materialism was developed by Aleksandr Zinov'ev (b. 1922),

who eventually had to emigrate and became a well-known writer.

In the 1970s and early 1980s censorship became more lax, allowing—although not without a struggle—the works of, and about, such authors as Solov'ev and Fedorov to be published. Alongside Vernadskii's ideas about the noosphere, Fedorov's doctrine of the "common cause" served as an inspiration for the loosely defined, nonofficial movement of cosmism. The latter was merged with Eurasianism by Lev Gumilev (1912–1992) who proposed a theory of ethnogenesis as a process affected by cosmic energy. All this signified a halting but perceptible expansion of the boundaries of philosophical discourse that increasingly weakened the hegemony of dogmatic Marxism.

Following Mikhail Gorbachev's reforms from the mid-1980s and until the dissolution of the USSR the hegemony of Marxism rapidly evaporated. One of the leading authors in official Marxism, Ivan Frolov (b. 1929) admitted in his study *Chelovek, nauka, gumanizm: novyi sintez* (Man, science, and humanism: A new synthesis, 1986) that the truths of Marxism were not, after all, absolute. The admission was an attempt to preserve the relevance of the doctrine in the new situation. The history of Soviet Marxism came to an end when the floodgates that held back previously suppressed philosophical literature, both Russian and foreign, finally opened. The return of the works of prerevolutionary and émigré Russian philosophers was the most remarkable part of this revival.

RUSSIAN PHILOSOPHY ABROAD. With the emigration after the 1917 Revolution and the expulsion of a large group of thinkers in 1922 Russian philosophy split into two strikingly unequal branches: the one inside and the other outside the country. The Bolshevik government's intolerance proved to be a blessing in disguise. While all independent philosophical thought was brutally suppressed in the Soviet Union, many of Russian philosophers abroad created the largest and the best part of their oeuvres. This was true of Berdyaev, Frank, Bulgakov, Shestov, and Il'in, as well as of the younger generation of philosophers among whom Georgii Florovskii (1893–1979) and Karsavin deserve special note. Russian thinkers in exile collectively created a body of literature that fulfilled the promise of the Silver Age as the Russian "religious-philosophical renaissance." A comprehensive evaluation of this literature remains a task for the future.

Among the diverse trends that existed in Russian philosophy abroad two seem particularly notable from

today's point of view: religious-philosophical and Eurasianist. The first was the continuation of the prerevolutionary religious idealism, whereas the second became yet another refraction of the old theme of Russia's destiny in a new situation created by the Bolshevik revolution. Berlin and then Paris were the centers of the first trend and Prague (as well as, briefly, Sofia), of the second.

Russian religious philosophy continued its preexile themes: critique of (Western) rationalism and the quest for integral knowledge; metaphysics of all-unity and sophiology; Russia's historical destiny cast in religious-idealist terms; and religious foundations of personhood.

The study of the history of Russian philosophy by this group became the culmination of the work begun in Russia. Zen'kovskii's two-volume *Istoriia russkoi filosofii* (History of Russian Philosophy, 1948–1950), Losskii's book of the same title (1951), Berdyaev's aforementioned essay on the Russian Idea, and Florovskii's *Puti russkogo bogosloviia* (Ways of Russian Theology, 1939) were towering achievements supplemented by numerous articles and essays by other authors. Their work was, collectively, the most important philosophical attempt to make sense of the Russian experience and especially of its last, vastly tragic phase. It is surprising how little would need to be changed, for example, in Frank's essay *Krushenie kumirov* (The Collapse of Idols, 1923), created before Stalin's repressions and World War II, if it were to be rewritten today.

Eurasianism began as a distinct movement with the publication of a collection titled *Iskhod k Vostoku* (Exodus to the East; Prague, 1921). It viewed Russia as straddling Europe and Asia in the geographic, geopolitical, and cultural-historical sense and enhanced the traditional Slavophile critique of the West by the Spenglerian sense of the "twilight" of Europe. Postcolonialist critique of Europe was prefigured in Eurasianism's claim that the western view of history merely promoted the West's ulterior interests under the guise of objective truth. The mistrust of the West was supplemented by the affirmation of the positive significance of the Asian element in Russian history and culture. Eurasianism had both a religious and a secular branch. The former was represented by such authors as Petr Savitskii (1894–1968) and Petr Suvchinskii (1892–1985), the latter by Florovskii and Karsavin. In Karsavin's case Eurasianism had a close affinity with the Solov'evian school. Nevertheless, for most Eurasianists religion was important only as a cultural-historical factor that contributed to the formation of Russia as a Eurasian entity. The religious theme in Eurasianism weakened especially after Florovskii left the movement. Some of his

secular opponents went so far as collaborating with the Bolshevik government that they saw as the heir to the cause of great Russian statehood. Those who returned to Russia, however, perished eventually in Stalin's concentration camps. Eurasianism as a political movement declined in the mid-1930s with the rise of National Socialism in Germany. Many of its members made significant contributions to the social and human sciences: George Vernadsky (1887–1973) in history, Nikolai Trubetskoi (1890–1938) and Roman Jakobson (1896–1982) in linguistics. Suvchinskii was a prominent musical critic. The political influence of Eurasianist ideas was restored to life in the post-Soviet period when they became a source of inspiration for a widely divergent spectrum of ideological schools of thought, ranging from nationalists dreaming of a new Russian Empire to Soviet-style Communists.

POST-SOVIET PERIOD. Rather than being resolved, philosophical questions were merely suspended by the ideological freeze during the Soviet period and once constraints fell old divisions quickly reemerged. During the early and mid-1990s Russian philosophers were primarily occupied with bringing back formerly suppressed patriarchy and rejoining the international philosophical dialogue. Berdyaev, Bulgakov, and Florenskii's writings were particularly favored during this period. But the list was quickly expanded to include the entire galaxy of Silver Age thinkers.

The second tendency—that is, restoration of contacts with the outside world—has by now resulted in a full spectrum of western and nonwestern influences without any apparent restrictions. Like several times earlier in history, Russian philosophers eagerly acquaint themselves with foreign philosophy: phenomenology, analytic philosophy, psychoanalysis, critical theory, poststructuralist thought, and a variety of nonwestern wisdom traditions. The old controversy between Slavophiles and Westernists was also apparently merely suppressed and has again become a notable factor in Russians' debates about their past, present, and future. The theme of the Russian Idea has returned in all of its prior permutations and now has been co-opted, among others, by communist authors who try to breathe new life into a doctrine that has lost much of its appeal. While the tradition of nonacademic philosophizing remains strong, the academy is now the backbone of philosophical life in Russia.

Soviet institutions, such as the Institute of Philosophy of the Russian Academy of Sciences and the journal *Voprosy filosofii* (Questions of Philosophy), have survived

their original ideological functions. The teaching of philosophy in higher education occupies the same place as elsewhere in the world and occurs without any ideological constraints. Literature for instruction in philosophy figures prominently among philosophical publications. The current output of academic philosophers embraces all disciplines of philosophy and represents all shades of opinion one finds elsewhere. Numerous works are published on the history of Russian philosophy; they include both special studies and historical surveys. Another notable feature is the striking decentralization of philosophical life that is no longer confined to "the capitals" but is active in many centers of higher learning in the country. There are no overwhelming political parties among Russian thinkers of the early twenty-first century. Neither the surviving communism nor the revived nationalism seem to hold commanding heights. If there is a threat to philosophy today it comes not from the state or radical ideology but from different quarters. Russian philosophy has joined contemporary western and nonwestern philosophical traditions in surviving the onslaught of mass culture. The new freedom and the rich intellectual, artistic, and literary legacy encourage hope, however, that Russian philosophy will rediscover not only its roots, but also the creative inspiration from which it first sprang.

Vladimir L. Marchenkov (2005)

RUYSBROECK, JAN VAN (1293–1381)

Jan van Ruysbroeck, the Flemish mystic, was born in the village of Ruysbroeck, near Brussels. He stood in close

relation to German contemplatives of the period, notably Meister Eckhart. In 1343 Ruysbroeck, together with two others, established a community at Groenendael that ultimately came under Augustinian rule. He was the prior of this community.

Ruysbroeck was not a trained theologian and had an imperfect knowledge of Latin. Though he made use in his mystical writings of language drawn from Eckhart, such as the “birth of Christ in the soul” and the “eternal Now,” he was sensitive to the kind of allegations of pantheism encountered by Eckhart and in fact directed against Ruysbroeck by Jean de Gerson. In his later writings in particular Ruysbroeck made it clear that he did not believe in the identification of the soul with God in the mystical state, and he criticized those contemplatives who gave up the active life and lapsed into quietism. He thus evolved a practical account of contemplation that connected it with good works.

Ruysbroeck distinguished between different phases of the good life, which should be practiced together. First, there is the active life of doing good works. This by itself will not bring blessedness, since it can mean moral self-reliance rather than dependence on God’s grace. But good works are a necessary part of the purification of the soul. Second, there is the practice of the inner virtues—faith, hope, and love. Third, there is the contemplative life, through which the soul may gain union with God. Those who attain this last condition are called “God-seeing.” They are not continually immersed, as it were, in this inner blessedness, but find themselves impelled to practice love and good works as a result of it. The practice of good works, suffused by the knowledge of God gained in the state of contemplative union, is what Ruysbroeck referred to as “the common life.” This, the ideal he tried to realize in his own monastic community, was interpreted as a reflection of the life of the Trinity, which was united in a common fruition analogous to that enjoyed by the mystic but was also outward-going through the creative power of God, analogous to the work of the monk in serving the society around him.

In order to illustrate the relation of union, yet difference, between the soul and God, Ruysbroeck made use of analogies drawn from human love, as the title of his major work, *The Adornment of the Spiritual Marriage*, indicates. Thus one should “rest in Him whom one enjoys.... There love has fallen in love with the lover, and each is all to the other, in possession and in rest” (*The Sparkling Stone*, 13). The love analogy had a certain aptness in bringing out both the sense of union and the necessary theistic distinction between the soul as creature

and the Creator. Ruysbroeck also made use of the Neoplatonic doctrine of eternal archetypes or forms, existing in God. Thus the ground of the soul is man's eternal archetype, and in realizing it in its purity and nakedness, the contemplative finds union with God. In this, Ruysbroeck, like other mystics of the period, exhibited the influence of Pseudo-Dionysius. He thus made use too of the notion that creatures proceed from God through the process of creation and return to him through contemplation. But since the creature needs to reflect the love displayed by God in the work of creation, so likewise the mystic must combine his return to God with the outgoing work of love.

Ruysbroeck's works were closely studied by those who belonged to the movement known as the Brethren of the Common Life, started in the latter part of the fourteenth century by Gerhard Groot, who knew Ruysbroeck. Thomas à Kempis belonged to this confraternity. Despite contemporary criticisms of his language as not always squaring with orthodox theology, Ruysbroeck was beatified by the Roman Catholic Church.

RYLE, GILBERT

(1900–1976)

Gilbert Ryle, the British philosopher, was born in Brighton. Having read Classical Honour Moderations and the Final School of Literae Humaniores (Greats) he went on to read the then newly established School of Philosophy, Politics and Economics at the Queen's College, Oxford. He became a lecturer at Christ Church in 1924 and in the following year a student and tutor, and he remained there until his appointment as professor at the

end of World War II. He was the Waynflete professor of metaphysical philosophy in the University of Oxford from 1945 to 1968. Ryle was largely responsible for the institution of the new degree of bachelor of philosophy at Oxford. He served as the editor of *Mind*, after the retirement of G. E. Moore, from 1947 until 1971.

Ryle's philosophical writings covered a wide range of topics. They fall mainly within the fields of philosophical methodology, philosophical logic, and the philosophy of mind, but the total spread is very wide and includes some work on the history of philosophy, especially on Plato. Only the fields of moral philosophy, political philosophy, and aesthetics are comparatively neglected. Much of his writing takes the form of articles addressed to the solution of quite specific issues, and it is impossible to discuss here seriatim his "Negation," "Plato's *Parmenides*," "Conscience and Moral Conviction," and "Heterologicality," to mention the titles of only four such papers.

Probably the best approach to Ryle's philosophical work is through his views on the nature and method of philosophy, which have developed in a consistent way after the end of a short and early flirtation with phenomenology. Many of his articles on specific topics seem to have a clear subordinate aim of illuminating these questions, while such important writings as "Systematically Misleading Expressions," his inaugural lecture, *Philosophical Arguments*, and the book *Dilemmas* are explicitly devoted to them. That *The Concept of Mind* can be regarded as an illustration of his views on philosophical method is a tribute to the consistency of his theory with his practice, though it would be an injustice to treat it merely as such.

Ryle's well-known article "Systematically Misleading Expressions" is important as being easily the first, although incompletely worked out, version of a view of philosophy closely akin to that which Ludwig Wittgenstein was then beginning to work out independently, and which is often spoken of as having been first suggested by Wittgenstein. This view treats philosophy as the activity of removing fundamental conceptual confusions that have their source in our overreadiness to construe grammatical similarities and differences as indicative of logical similarities and differences. For example, since either unpunctuality or the unpunctual Smith may, with grammatical similarity, be said to be reprehensible, some philosophers are inclined to conclude that similar things are being said of two objects, Smith and unpunctuality; hence, the world is thought to be populated by two kinds of objects, universals and particulars. Again, since "Mr. Baldwin is a statesman" is grammatically similar to "Mr.

Pickwick is a fiction,” philosophers have been tempted to suppose that the world contained fictions alongside of statesmen.

However, Ryle’s view is not fully worked out at this stage. Writing in a climate of opinion in which philosophy was widely regarded as the activity of analysis by which the true logical form of facts was explicitly displayed and the test of adequate language was taken to be a one-to-one correspondence with the form of facts, he did not entirely free himself from its influence. As a result, he cannot regard the reformulation of statements in a way that removes misleading grammatical similarities as merely a useful expedient for making ourselves aware of important differences between them; the reformulation is still thought of as the revelation of the true form of the fact, so that “Baldwin is a statesman” is, in an absolute sense, a correct form of utterance, while “Pickwick is a fiction” is incorrectly formulated.

This anomalous relic of logical atomism caused Ryle uneasiness even then, and it does not appear again. If we neglect it, we may regard “Systematically Misleading Expressions” as an exposition of a view that Ryle never abandoned, although he did refine it. One such refinement is found in *Dilemmas*. Here it is claimed that many philosophical problems, if not all, immediately present themselves in the form of dilemmas: We find ourselves holding, without the possibility of sincere repudiation, two or more opinions that seem to be incompatible (that, for example, we often choose responsibly what to do, and that we are what we are through our natural endowment as modified by environment—the problem of free will). Such dilemmas must be overcome by showing that the apparent conflict is a consequence of conceptual confusion rather than by choosing one horn on which to be impaled.

The emphasis is somewhat different in *Philosophical Arguments*. While in “Systematically Misleading Expressions” and in *Dilemmas* the emphasis is on the activity of freeing ourselves from conceptual errors and puzzlement, in *Philosophical Arguments* the more constructive side of the procedure is stressed. By methodically determining what can and what cannot be said without absurdity, which inferences are valid and which are invalid, which grammatical parallels are likely to mislead and which are not, we come to see better the “logical geography” of our conceptual system—how different concepts are related to each other and what are the different roles that they play. There is no essential conflict between the view of Ryle’s philosophical procedures as “removing conceptual roadblocks” and “freeing conceptual traffic jams,” to echo the

metaphor employed in *Dilemmas*, and the more constructive view of them. Thus, it would be idle to ask whether, or at which stages, *The Concept of Mind* is correctly viewed as exposing the confusion of “the ghost in the machine,” into which we are led by grammatical analogies, or as mapping the extension and boundaries of such interrelated concepts as “will,” “intelligence,” “imagination,” “thought,” and the like; the two aspects are not thus separable.

Ryle often expressed this view of philosophy in terms of the notion of a category mistake, as in *The Concept of Mind*. A category mistake occurs when something is taken to belong to a different category from its true one. Neither in *The Concept of Mind* nor elsewhere is any serious attempt made by Ryle to give a rigorous account of the notion of a category, although there is a historical discussion of it in “Categories,” and Ryle sees this notion as akin to Bertrand Russell’s notion of type. Although this is a gap, it is probably of little direct importance to the argument of *The Concept of Mind*. The essential thesis here is that there is a special kind of confusion that can be illustrated by that of taking team spirit as an element in a game as being on equal footing with serving or receiving, of taking a division as a military formation as being on equal footing with its component regiments, of taking Oxford University as an institution as being on equal footing with its component colleges. Ryle then goes on to claim that traditional Cartesian dualism treats the mind as an entity on equal footing with the body and mental activities as being on equal footing with bodily activities, and that this is a confusion of the same kind as those in the three illustrative cases. The language of category mistakes is not essential; Ryle could have used his terminology of 1931 and said that just as the grammatical similarity of “Jones gave an exhibition of dribbling” and “Jones gave an exhibition of ball control” could mislead us into thinking that Jones was giving two independent and simultaneous exhibitions, so the grammatical similarities between our talk of mental and bodily activities could mislead us into thinking that they were independent and simultaneous activities.

Such a misconception Ryle calls the dogma of the ghost in the machine. He attempts to show its falsity in a series of chapters on the main aspects of mental life, in which the arguments fall into two main classes. On the one hand he tries to show that the dogma of the ghost in the machine fails in its explanatory task and is logically incoherent, leading to such logical evils as vicious infinite regresses. On the other hand he tries to show that a satisfactory positive account of mental phenomena can be

given, without invoking the ghost, in terms of such things as style of performance, dispositions to certain characteristic performances, and acquired skills. Thus, if a person does a physical action while thinking about what he is doing, we must take it not that the ghost discursively thinks and the bodily machine moves but that the person performs bodily in an appropriate way, while being disposed to perform other actions if the occasion arises.

One chapter in the book is a restatement of the argument of the paper "Knowing How and Knowing That," published in 1946, and it is a plausible inference that this paper was the germ from which the larger enterprise sprang. In that article Ryle suggested that philosophers commonly take it that knowing how to do something is knowing the truth of certain principles and applying them to an activity. He pointed out that although a given cook may learn to cook from a cookbook, the principles of cookery are logically a distillation from the practice of those who know how to cook, just as the principles of valid argument are a distillation from the practice of those who know how to argue. Thus, knowing how to do things, being able to perform intelligently, is logically independent of any interior theorizing; therefore it involves a display of intelligence that others can witness, rather than a mechanical event from which we have to infer a piece of unwitnessable ghostly theorizing. *The Concept of Mind* attempts to extend the same line of thought to other mental phenomena.

It should be noted that Ryle is not content with the "weaker" thesis that overt human actions must not be analyzed as mechanical events brought about by non-physical, ghostly activities. In fact, he adopts the far stronger thesis that all references to the mental must be understood in terms of, in principle, witnessable activities. We must not only avoid ascribing the skill of a skillful driver to a ghostly "inner" driver, but we must also explain all mental life, including emotion and feeling, in terms of the witnessable. Certainly it is this feature of his book that has led many, with considerable plausibility, to class Ryle as a philosophical behaviorist, though he repudiated this label in advance. Ryle, indeed, sometimes refers to "twinges," "throbs," "flutters," and "glows" in his characterization of feelings in a way hard to reconcile with behaviorism, but it is notoriously difficult to see how such terms are not a relic of the essentially private in Ryle's public world. By adopting this stronger thesis Ryle avoids well-known difficulties about knowledge of other minds and privacy; however, it is not clearly required for the basic program, and much that he has to say is independent of it.

Much of the interest of this modern classic is independent of the question whether Ryle succeeds in demonstrating any general thesis. The detailed discussions of thinking, knowledge, will, emotion, sensation, intellect, and the like have great independent interest. In the course of these discussions Ryle introduces a number of philosophical distinctions, such as those of "task and achievement," "avowal," and "mongrel-categorical," that have become the common tools of modern philosophical discussion. The whole character of philosophical discussion of the mind has been decisively changed, even in quarters where Ryle's conclusions are strongly challenged, by the appearance of *The Concept of Mind*.

Another set of problems to which Ryle devoted a number of papers are those concerned with the concept of meaning. Here his review of Rudolf Carnap's *Meaning and Necessity in Philosophy*, his "The Theory of Meaning," published in *British Philosophy in the Mid-century*, and his contribution to the symposium "Use, Usage and Meaning" in the *PAS* supplementary volume for 1961 deserve special mention. One main contention in these articles is that it is words that are the bearers of meaning, and whose meanings have to be taught and learned, rather than sentences. To learn a language is to acquire a vocabulary and a syntax; this language is then used in speech, which is an activity that one performs by means of a language. The sentence is a unit of speech, not of language. The theory of meaning is therefore concerned primarily with words, not with sentences; but this theory, Ryle holds, has been often vitiated by a simple model of meaning that he calls the "'Fido'-Fido" theory, one that seeks always to find as the meaning of a word something that stands to that word rather as the dog Fido stands to the name "Fido." J. S. Mill partly emancipated himself from the theory by distinguishing connotation from denotation, but he continued to say that meaning was connotation and denotation. In the review of Carnap mentioned before, Ryle attempts to show that the "'Fido'-Fido" theory is still not an outworn fallacy but something that continues to vitiate much sophisticated modern work.

It is notable that the bulk of Ryle's philosophical writing avoids, rather than lacks, any historical discussion. There is the very minimum of reference to even recent learned controversy, and the great philosophers are rarely given even a casual mention. In *The Concept of Mind* the expression "Cartesian dualism" is a nickname for a kind of view that Ryle had once held and to which he thinks many are prone rather than a genuine historical reference. However, this is a policy of segregating the his-

tory of philosophy from the treatment of problems, not a sign of lack of interest in the history of philosophy. Ryle's historical interests, though eclectic, are wide. They have, however, centered on Plato; in addition to already published articles on Plato, Ryle devoted much work to problems arising from the Platonic dialogues, and further publications in that field may be expected.

In conclusion, a word should be said about Ryle's highly individual style, for it is of more than literary interest. It is peculiarly his own, so that it would be impossible for anyone familiar with it not to recognize his work from even a few sentences. One hallmark is the freshness of the vocabulary; although he liberally coined technical terms when he needed them, he always avoided the well-worn counters of philosophical exchange. Another hallmark is that although the general style is informal, the choice of words is literary rather than colloquial; this is achieved by the use of a vocabulary more novelistic than learned. Although there is much close argument in his writing, the importance of the fresh language, the bold metaphor, and the terse epigram in giving the problem a striking presentation, in bringing down pretentious castles of learned jargon, and in making his own contention memorable is very great indeed.

RYLE, GILBERT [ADDENDUM]

From Gilbert Ryle's death in 1976, and through the late 1990s, his views were not the focus of much philosophical attention. Studies of his thought have been published (e.g., Lyons 1980; Stroll 2001) and his character and role in Oxford have been illuminated by the memoirs of others (e.g., Mabbott 1986).

Ryle's own approach to the understanding of psychological concepts was superseded by the emergence of the psycho-physical identity theory, mainly because his analytical concentration on (behavioral) dispositions, of whatever complexity, seemed not to confer a sufficiently real status on lots of psychological processes, for example, feeling a pain or occurrent thinking.

His most lasting intellectual legacy has been the supposed distinction between knowing how and knowing that, which has remained part of philosophical folklore since he propounded it. According to Ryle knowing how to F is distinct from any knowledge that a proposition is true, amounting rather to a capacity to do the action in question. Ryle's distinction has been relied on by those (e.g., David Lewis) who have tried, when answering certain antimaterialist arguments, to give a practical, non-factualist account of knowing what an experience is like. However, considerable skepticism is being generated about Ryle's distinction (e.g., in Stanley and Williamson

2001; Snowdon 2003). Thus, someone who is injured can know how to do something even though he or she is unable to do it, and much knowhow seems to be knowledge that some way is the way to act. These criticisms have been resisted (e.g., Koethe 2002; Rumfit 2003). There is considerable debate and it remains to be seen whether this aspect of Ryle's thought will suffer the fate of the rest.

SAADYA

(882–942)

Saadya, sometimes called al-Fayyumi from the section of Upper Egypt in which he was born, had a brilliant career as the most distinguished intellectual leader of Jewry in his age. He was twenty-three when he left his Egyptian home to play his part on the wider stage of Palestine, Syria, and Babylonia. By this time he had already composed the first known Hebrew dictionary and an important treatise refuting the views of Anan ben David, the founder of the rationalistic Karaite sect. In 921, the rabbis of Babylonia challenged the authority of the Palestinian rabbis to fix the Hebrew calendar. Saadya's defense of the position of the Babylonian rabbis was most effective; he was rewarded by appointment to the rabbinical academy at Sura in Babylonia; and a few years later, in 928, he was the first non-Babylonian ever to be named as the head (*gaon*) of the academy. His tenure of this position was neither calm nor prolonged. Disputes with the exilarch of the Babylonian Jewish community led to the removal of Saadya and his retirement from active participation in the life of the community. His last years saw a burst of literary creativity.

The writings of Saadya truly signaled the birth of a new creative period in Jewish life. He was a pioneering student and productive scholar in many fields of Jewish concern, including Hebrew grammar and philology, biblical exegesis, and Jewish liturgy. The early attacks on the views of Anan were followed by a long series of writings against Anan's fellow sectarians; since Karaism, a movement that rejected rabbinical and Talmudic law, was at this time the major internal threat to the unity of Jewish life, Saadya's anti-Karaite polemics continued throughout his career. The primary activity of Saadya's public life was in the legal field, and here his contributions were outstanding. In addition to commentaries on Talmudic treatises, Saadya wrote at least ten systematic monographs on a variety of Jewish legal subjects; one of these, *Inheritance*, is preserved in its entirety in the Bodleian Library at Oxford. It was published in 1897 under the editorial care of Joel Mueller. Fragments of others still exist. Saadya was the first to translate the Old Testament into Arabic; this translation, still in use, is notable for its use of paraphrase where a literal translation would have been subject to censure for anthropomorphism. He also composed the earliest known commentary on *Sefer Yetzira* (The book of creation), an important work of the Jewish mystical tradition.

Thus his major philosophical work, *The Book of Beliefs and Opinions* (Arabic title, *Kitab al-'amanat wali' tikadat*; Hebrew title, *Sefer ha-emunoth weha-deoth*), probably completed in 933, is but one of a long list of eminent contributions for which Saadya is remembered. He was probably impelled toward a systematic consideration of the relation between the religious beliefs of Judaism and the opinions arrived at through rational investigation both by the comparable activities of Muslim philosophers—the *kalam* and other schools—and by the quasi-rational approach characteristic of most of the Karaite spokesmen. In the intellectual milieu of the tenth century, the philosophical issues with which Saadya was concerned were widely and thoughtfully debated. Muslim philosophers of this age had far more of the corpus of Greek philosophical literature available to them than had their compeers in the Christian West. Saadya's *Book of Beliefs and Opinions* may best be described, therefore, as a philosophical apologetics for rabbinite Judaism. The Mu'tazilite school of Muslim philosophers generally presented their systematic treatises in the form of theodicies, treating first of the unity of God and then of his justice. Saadya's philosophical work is similarly patterned but assigns a rather larger share of the discussion to the second, ethical part than to the first, more purely metaphysical and theological one.

Prefaced to the ten sections into which the body of the work is divided is an introductory treatise in which Saadya justifies his engaging in this sort of philosophical enterprise. Here he enters into questions of the sources of human knowledge, the relations of belief and doubt, and the prevalent view that rational speculation necessarily leads to heresy. He argues that not the use of reason, but exclusive dependence on human reason is undesirable. Properly used, in combination with revelation, rational speculation supports revealed religion. From this discussion Saadya moves, in the first major section, to a proof of the doctrine of creation out of nothing and a refutation of twelve contrary views. In the second major section of his book, Saadya discusses the unity of God and demonstrates how the Christian doctrine of the Trinity is based upon a misinterpretation of certain scriptural verses. Treatise three defends the idea of a divine law for God's creatures as a necessary demand of reason and urges the need for prophecy and prophets as the vehicle by means of which the divine law is transmitted to men.

From the fourth treatise to the end of the work, Saadya's concern is more with ethical questions and the consequences for men's future redemption of their obedience or disobedience to the divine precepts delivered by

the prophets. In these sections, he defends on rational grounds all of the major doctrines of the Jewish tradition. The tenth and last treatise is of slightly different character; it presents an ethic of the middle way as the proper guide to man's conduct in the affairs of daily life. Thus we may say that Saadya concluded his work on religious philosophy with a secular ethic.

Bibliography

Les oeuvres complètes de Saadia was edited by J. Derenbourg (6 vols., Paris, 1893–1896). Saadya's *Book of Beliefs and Opinions* may be found in a translation from the Arabic by Samuel Rosenblatt in the Yale Judaica Series, Vol. I (New Haven, CT: Yale University Press, 1948).

For material on Saadya, see Jacob B. Agus, *The Evolution of Jewish Thought* (New York and London: Abelard-Schuman, 1959); Joseph L. Blau, *The Story of Jewish Philosophy* (New York: Random House, 1962); Julius Guttman, *Philosophies of Judaism*, translated by D. Silverman (New York: Holt, Rinehart and Winston, 1964); Isaac Husik, *History of Mediaeval Jewish Philosophy* (New York: Macmillan, 1916); Henry Malter, *Saadia Gaon: His Life and Works* (Philadelphia: Jewish Publication Society of America, 1921); and *Three Jewish Philosophers. Philo, Saadya Gaon, Jehuda Halevi*, selections with introductions by H. Lewy, A. Altman, and I. Heinemann, eds. (New York: Meridian Books, 1960).

J. L. Blau (1967)

SAADYA [ADDENDUM]

882–942

Saadya's intellectual career was characterized by polemic and defense of rabbinic Judaism. As head (*gaon*) of the rabbinic academy of Sura in Babylonia in the first third of the tenth century, Saadya felt compelled to respond to the Karaites, those who challenged the authority of rabbinic Judaism. Saadya's major philosophical work, written in Arabic, *Kitāb al-Āmānāt wa'l-Ī-tiqādāt* (The book of doctrines and beliefs) should be understood in large part as a defense against the Karaites. Following the Muslim Mu'tazilites, who emphasized divine justice and unity, Saadya's *Āmānāt* focuses on creation, divine unity, divine law and justice, and reward and punishment in this world and posthumously.

Prefacing the particular discussions just noted, Saadya outlines the sources of human knowledge and understanding, and of error. The senses can be unreliable, reason may be derailed if inferential skills are lacking, and overarching all of this is the propensity to impatience in

inquiry. For Saadya, the sources of error and doubt are both intellectual and moral. Human beings are frail creatures, and as a result, out of benevolence God provided humankind with a superhuman source of insight and true belief—the prophetic tradition—encapsulated in scripture and in the oral tradition of the rabbis. In advance of people’s (slowly and laboriously) discovering the truth unaided, God has provided them the answers through his prophets. In this way revelation and reason, revealed religion, and rational speculation coincide over time. Revelation provides an anchor for humans as they quest for knowledge. As Alexander Altmann puts it on behalf of Saadya: “Revelation is not essentially superior, but historically prior to Reason and has an educational function in the evolution of humanity” (1946, p. 18 [2002]). Maimonides viewed Saadya’s project as less than philosophical, assuming conclusions that ought to be proved. But Saadya’s defense against this would be that revelation of the truth provides just the starting point for patient inquiry.

SABATIER, AUGUSTE

(1839–1901)

Auguste Sabatier was perhaps the Protestant theologian most influential in the early twentieth century. Many Catholic modernists as well as Protestant liberals believed that his philosophy of religion had achieved its object, a reconciliation between the essential verities of Christian experience and the demands of science. Sabatier was a professor of reformed dogmatics at Strasbourg and Paris and a sometime journalist and literary critic. He ended his career as dean of the Theological Faculty of Paris.

Sabatier described his theory of religious knowledge as “critical symbolism.” By this he meant to indicate that religious doctrine and dogma are attempts to symbolize the primary and eternal religious experience (or consciousness) of the believer. He taught that the doctrines of historical religions are secondary, temporal, and transient symbols of this central religious experience. Christian dogmas, then, are necessarily inadequate attempts to “express the invisible by the visible, the eternal by the temporal, spiritual realities by sensible images.” Christ and his disciples through the ages have experienced the divine presence of God the loving Father and with it a sense of moral repentance and an inner energy of the spirit. As with all personal experience, no symbolic structure can act as substitute. Such structures are, in every field, merely hypothetical attempts to grasp experience.

Correspondingly, Sabatier held that the cosmologies, legends, dogmas, and statements about the world and man propagated by historical religions in an attempt to

express and communicate the fact of religious experience can claim only derivative and relative validity. Moreover, they are conditioned by the state of science and philosophy as understood by those who create such religious symbolism. And just as science and philosophy do not give absolute and final truth, neither does religious dogma—hence the decline of older religious symbolism with the progress of science. God lives in man’s consciousness, not in dogmas and cosmologies. Man’s need for and experience of God’s presence prove his existence. Science and philosophy are masters of their own proper domain. Thus, “God is the final reason of everything, but the scientific explanation of nothing.”

Sabatier’s critical symbolism was exceedingly Protestant in that it rejected Catholic dogmatic absolutism for the absolutism of justification by faith. It appealed to many modern religionists of his day because it seemed to retain valid science and yet avoid positivistic nihilism and agnostic defeatism. Putting personal experience above theories about experience, Sabatier’s approach was found congenial in an age that produced Henri Bergson and William James. Like them, Sabatier seemed to give moral claims and value judgments a renewed truth. To know a thing religiously, Sabatier held, is to experience the sovereignty of spirit and to estimate the object known as a means or obstacle to the true moral life of the spirit. Teleology is reintroduced along with objective value, and the meaning of life, as well as the will’s freedom to choose good or evil, is made manifest. Sabatier’s theories could easily be adapted to the neo-Kantian and neoidealist tendencies at work in philosophy, social science, political ideology, literature, and art in the new century. His continued influence seems assured, for by basing the truth of religion on the personal experience of the believer, he joined the long line of “crisis” and existential theologians of our time.

SAINT-HYACINTHE, THÉMISEUL DE (1684–1746)

The real name of Thémiseul de Saint-Hyacinthe, the French freethinker, was Hyacinthe Cordonnier. Born at Orléans, he was unjustly reported to be the son of Jacques Bénigne Bossuet. His ambitious mother induced him to change his name and to become a cavalry officer. Later he devoted himself to the study of ancient and modern languages in Holland, from which he had to flee because of a jealous husband and to which he later returned because he had seduced one of his pupils. He became an editor of the new *Journal littéraire* (1713) and wrote in favor of the moderns. In 1714 his anonymous *Le chef-d'oeuvre d'un inconnu*, a satire of pedantry, won him notoriety. He eloped to London in 1722 with the daughter of a nobleman. He stayed there for twelve years, became a member of the Royal Society, and began a long and gratuitous quarrel with Voltaire, whom he offended in a satirical play (*Déification d'Aristarchus Masso*, 1732). He returned to Paris in 1734 and later moved to Holland, where he died in 1746.

Three of Saint-Hyacinthe’s writings are worthy of mention. The first book, *Le chef-d'oeuvre d'un inconnu*, is a bizarre work that could easily be a satire on the *explication de texte* method, as it is practiced in some milieus. His last book, *Recherches philosophiques sur la nécessité de s'assurer par soi-même de la vérité* (1743), is a defense of the power of reason to find truth and of its right to do so. He also argues for the moral-sense theory, with which he probably became familiar during his stay in England. His discussion of words as signs of ideas points toward linguistic analysis. Other chapters deal with demonstration and evidence, matter and the soul.

In between these two works, Saint-Hyacinthe wrote his interesting *Lettres écrites de la campagne* (1721). This potpourri is a long conversation treating of many subjects, moral and epistemological. He discusses truth in the light of John Locke’s definition; evidence for certitude, following the Cartesian *cogito* and the principle of contradiction. He proposes a methodology for discovering

the truth that is also Cartesian. Most interesting is his recognition of the nihilistic challenge to moral values that was becoming more vigorous at the time. The longest section of the book expounds the argument that moral nihilism is justified and that all moral values disappear if God does not exist. Saint-Hyacinthe's real purpose was to urge men to believe in God, but the effect of his argument was more likely to lead them to immoralism, for he expounds that doctrine forcefully and endeavors to make it an impregnable position except in the face of God's existence. These little-known pages are notable as the most systematic exposition of moral nihilism before the Marquis de Sade. The *Lettres* had some success, and were translated under the title *Letters Giving an Account of Several Conversations Upon Important and Entertaining Subjects* (2 vols., London, 1731).

Among Saint-Hyacinthe's other publications are the *Lettres à Mme. Dacier* (1715, concerning the *querelle d'Homère*); "Lettre à un ami, touchant le progrès du déisme en Angleterre" (in his edition of *Mémoires concernant la théologie et la morale*, 1732); and the novel *Histoire du prince Titi* (1735).

SAINT-SIMON, CLAUDE- HENRI DE ROUVROY, COMTE DE (1760–1825)

The French social philosopher, Claude-Henri de Rouvroy, Comte de Saint-Simon, the founder of French socialism, was the eldest son of an impoverished nobleman. He was educated privately by tutors, among them the encyclopedist Jean Le Rond d'Alembert. Beginning a military career at the age of seventeen, he took part in the American Revolution and was wounded at the naval battle of Saintes in 1782. Despite subsequent disclaimers, Saint-Simon actively supported some of the measures introduced by the French Revolution of 1789. He renounced his title; he also drew up the *cahier* of his locality for the Estates General and presided at the meeting at which his commune elected a mayor. Although his revolutionary zeal earned

him two certificates of *civisme*, his activities were not wholly disinterested. He took advantage of the sale at low prices of church and *émigré* property by making considerable purchases. He was arrested in 1793, but since it transpired that a mistake had been made, he was released the following year. He was active in political life under the Directory, among other things participating in the peace negotiations with the English at Lille.

Saint-Simon finally retired from governmental and financial activity and embarked on the career of writer and prophet that continued until the end of his life. He first studied physics for three years, at the same time forming friendships with a number of leading scientists and writers whom he helped to support. Later he traveled extensively, especially in Germany, England, and Switzerland. It was not until 1814, however, when he found an able and enthusiastic collaborator and disciple in the future historian Augustin Thierry, that his writings began to reach a wide public, particularly among the managers and businessmen who had risen to positions of influence during the Napoleonic era. The list of subscribers for his publication *L'industrie*, the first number of which appeared in 1816, included various prominent industrialists and bankers. The next year Saint-Simon's partnership with Thierry ended, and he began an association with Auguste Comte—an event of considerable significance, for it was in Comte's later work that some of Saint-Simon's fundamental conceptions were given more systematic and trenchant expression than their originator had been able to achieve. The collaboration between these two forceful personalities lasted for seven years but was finally broken by a quarrel in 1824, the year before Saint-Simon's death.

IDEALS AND REALITY

"The philosophy of the eighteenth century has been critical and revolutionary; that of the nineteenth century will be inventive and destructive" (*Oeuvres complètes*, Vol. XV, p. 92). This remark accurately reflects the position that Saint-Simon envisaged himself as occupying in the history of political and social ideas. He in no way wished to underestimate the achievements of his Enlightenment predecessors the *philosophes*, who by their bold attacks upon the traditional frameworks of thought and their criticisms of existing institutions had prepared the way for the vast upheaval of the French Revolution. Saint-Simon saw in the writings of such men as Étienne Bonnot de Condillac and the Marquis de Condorcet anticipations of his own belief that human affairs should be approached in a scientific, Newtonian spirit of inquiry,

and he sympathized with their contention that religious dogmas had over the centuries become the means by which the mass of the people had been held in ignorant and superstitious servitude to their rulers. He also shared the humanitarian and internationalist ideals that had inspired the work of his predecessors. (His subscription to these ideals, apparent in all his main publications, was perhaps most distinctively expressed in *Nouveau Christianisme* [Paris, 1825], an essay that appeared at the very end of his life.)

On the other hand, Saint-Simon's work also pointed forward to the quite new ways of conceptualizing and interpreting social relations that were later to gain wide currency through the writings of Karl Marx. In particular, Saint-Simon exhibited a far firmer grasp of the conditions that determine and mold historical change than had earlier thinkers, and this profoundly affected the form taken by his own practical recommendations. Sincerely held utopian ideals, even when carefully worked out in detailed political programs, were by themselves quite useless, he held, if they did not take account of these conditions. Utopian changes, if put into effect, were likely to result in a vacuum that would eventually be filled by forces as undesirable as those which had been expelled. The destruction of outdated institutions was one thing; their replacement by others of lasting validity, adapted to the technological, economic, and social requirements of the time, was another. This was surely the lesson of the French Revolution. Had not the high hopes and aspirations that marked its beginning ultimately foundered in atrocities, suffering, and tyranny?

HISTORICAL CHANGE

Despite the importance he assigned to it, Saint-Simon never set out his conception of historical change and development in a precise or systematic form. Like his other contributions to social theory, it was put forward in a somewhat disjointed and piecemeal fashion. Nevertheless, an outline of his view can be extracted from various works, notably from his writings in the periodical *L'organisateur* (Paris, 1819–1820). Saint-Simon spoke as if he had discovered a necessary law of evolution valid for all societies at all times, but the kernel of what he had to say was actually based upon a single instance, the transformation that had overtaken European society since the feudal period. The chief originality and importance of his analysis of how this change came about lay in his recognition of the role played by the emergence and conflict of classes and of the way in which such conflict issues in new forms of political organization and of ideology adapted

to the interests of the socially and economically dominant class. The institutions and beliefs of the Middle Ages fulfilled a perfectly intelligible, and indeed necessary, function from the point of view of the stage of development society had at that time reached (it is notable that Saint-Simon's approach to medieval history was considerably more sympathetic than that of either his Enlightenment predecessors or his liberal contemporaries).

Only later, with the enfranchisement of the communes, the emergence of a class of independent producers, and the subsequent growth of an industrial system of production under the impact of scientific and technological advances, did feudal organization become evidently anachronistic. Then the very features of the framework that had provided medieval society with the protection and unity of purpose it required impeded the free development of the new forces germinating within it. Thus, the seventeenth and eighteenth centuries witnessed the culmination of two major developments. On the one hand, there were increasingly effective attacks by the commons against privileges and institutions that had outgrown their social utility; on the other, the doctrines of the church, which during the Middle Ages had performed valuable services but which had been rendered obsolete by scientific discoveries, were subjected to a series of unanswerable criticisms. The net result was "the ruin of the old system in its parts and as a whole" (*Oeuvres complètes*, Vol. XX, p. 104).

ECONOMIC AND POLITICAL PROGRAM

The lessons Saint-Simon drew from previous developments for his own time were far-reaching. Although the old order was in a general condition of dissolution, it had still not been wholly superseded. Many of the chief centers of power and influence remained in the hands of "more or less incapable bureaucrats" (*ibid.*, pp. 17–26), idlers, and ignoramuses who owed their positions to the accident of birth or inherited wealth and who were in effect no better than destructive parasites. To a considerable extent "men still allow themselves to be governed by violence and ruse" (*ibid.*). In order to remedy this state of affairs, Saint-Simon appealed directly to the leaders of the new class of *industriels*, claiming that the hour had arrived for them to take into their own hands the management of society and thereby complete the revolution that had been maturing for so long. Only if this were done could society be reorganized in a way that would ensure its direction by efficient administrators, men who would see that those who could make a genuinely pro-

ductive contribution to its advance and prosperity were no longer ignored or exploited and received, instead, their appropriate reward.

Yet despite his insistence on the need for social justice, Saint-Simon had little faith in political democracy. He envisaged a hierarchical system, characterized by equality of opportunity rather than equality of wealth and run on explicitly elitist lines. The central administration of the community would consist of three chambers—the chamber of invention, the chamber of examination, and the chamber of deputies. Of these the first was to consist of artists and engineers who would propose plans, the second of scientists who would critically assess the proposals and also control education, and the third of captains of industry whose function would be executive and who (Saint-Simon somewhat optimistically assumed) would give just consideration to the interests of all members of the industrial class, workers and managers alike. Saint-Simon appears to have thought that in the type of society he had in mind, which would be rationally planned in a manner advantageous to all, there would be little or no need for the use of force to compel obedience to law and that government in the traditional sense would no longer be required. There is a clear anticipation of the Marxian conception of the withering away of the state.

ETHICS AND RELIGION

Saint-Simon was always conscious of the importance of moral and social ideals in helping to promote harmony and a sense of purpose in human communities. In medieval times the Christian religion had performed this role, and he thought that there was a place for a comparable system of beliefs, adapted to contemporary knowledge and interests, in any viable modern society. For the creation of such a system he initially looked to philosophy, but in his later years he recommended a return to the fundamental tenets of Christian teaching. The ethical doctrines of Christianity, he held, retained their validity even if the theological and metaphysical dogmas associated with them are no longer acceptable.

INFLUENCE

It is impossible in a short space to do justice to the fertility and originality of Saint-Simon's thinking on what he called social physiology. An untidy, impatient, and inelegant expositor of his own ideas, he nonetheless understood the central issues of his time better than many of his contemporaries and exhibited a keener insight into the economic and technical realities that lie beneath the surface of political arrangements and change. Marx indis-

putably owed a significant debt to him, but Marx was only one among a host of nineteenth-century thinkers who profited in one way or another from Saint-Simon's perceptive and imaginative mind.

SAINT VICTOR, SCHOOL OF

The Augustinian house of canons at St. Victor in Paris was founded in 1108 by William of Champeaux, the cele-

brated logician and theologian who retired there from the schools of Paris after undergoing a religious conversion and after Peter Abelard's attacks on his realism. The abbey survived until the French Revolution, but in the twelfth and early thirteenth centuries it was especially famous for its public school and for the distinction of the masters and canons who resided and taught there. From William, St. Victor derived high religious ideals, a leaning toward the conservative theological tradition of the school of Anselm of Laon, and an active interest in the work of other Parisian schools. Its masters mediated between the theological orthodoxy and strictness of the Cistercians—Bernard of Clairvaux was a friend to St. Victor—and the intellectual adventurousness of such secular masters as Abelard. St. Victor in the twelfth century combined Scholasticism and mysticism and exerted a most powerful influence upon the development of both philosophical and theological thought in that century. Not only did it possess among its canons some of the ablest writers of the age but it also attracted as long-staying guests such celebrated teachers as Peter Lombard and Robert of Melun. Besides producing a wealth of literature, its leaders also contributed to the fall of Abelard, to the damping of the enthusiasms of the Chartrains, to the containment of Gilbert of Poitiers, and to the correction of the Christological errors that abounded in the mid-twelfth century.

HUGH OF ST. VICTOR

St. Victor, unlike Chartres, was not devoted to the liberal arts. No commentary upon a nontheological text is known to have been written there, and purely literary writings were even relegated by the greatest Victorine, Hugh (d. 1141), to the position of mere appendices to the liberal arts. The Victorines did not encourage profane studies for their own sakes. The extreme, fanatical Walter (d. circa 1180) intemperately denounced the Aristotelian spirit of Abelard, Gilbert of Poitiers, William of Conches, and Peter Lombard. Absalon (d. 1203), too, warned against the dangers found in Aristotle.

Hugh vigorously challenged his humanist contemporaries who in the first half of the twelfth century thought more often of pagan philosophy than of Christ and his saints. Against the Chartrains he insisted upon the disparity between the cosmogony of Plato's *Timaeus* and Christian truth. Nonetheless, in his *Didascalicon* (which contains a program of Christian education) Hugh shows that he was thoroughly immersed in secular studies as the preliminary to divine science, for he considered the arts an indispensable aid to the understanding of

Scripture. Hugh sought to pass through knowledge to wisdom and to promote that participation in the divine Wisdom for which man was made. Similarly, Godfrey (d. after 1194) also affirmed that the liberal arts and theology were inseparable and that together they offered a complete education.

Philosophical elements are found scattered in the writings of the Victorines. Inheriting the Boethian-Aristotelian theory of abstraction, Hugh appreciated the necessity for logic without exalting it as highly as did Abelard. In physics Hugh maintained the atomic theory of matter and accepted the principle of the conservation of matter. His psychology was Augustinian, and he found the proof for the existence of the immaterial soul in the fact of its self-consciousness.

RICHARD OF ST. VICTOR

Both Hugh and his disciple Richard (d. 1173) describe the ascent of the soul in contemplation; Richard especially is the theorist of the degrees of love. But whereas Hugh insisted upon the inadequacy of reason and the necessity for faith, Richard, who rivaled Hugh as a spiritual writer, was more scholastic and laid a stronger emphasis upon dialectic to supplement the traditional scriptural and patristic authorities. Inheriting from Anselm of Canterbury his zeal to search for the "necessary reasons" of faith and for an understanding of belief, he accounted for the trinity of persons in God in abstract style with a very original dialectic of mutual love; he was also the first medieval thinker to provide, in one of the great speculative achievements of the period, an empirical basis in the principle of causality for a proof of God's existence.

VICTORINE THEOLOGY

Essentially the Victorines provided a theology for contemplatives within the cloister rather than for the schools. Hugh was a systematizer of theology on Augustinian lines, using dialectic when needed. Richard became the mystical doctor of the later Middle Ages. Both Hugh and Richard were biblical exegetes and spiritual writers, and it is for this that they and such other Victorines as Andrew (d. 1175) and Gamier (d. 1170) and the poet Adam were best known in the Middle Ages. Godfrey was more pronounced in his humanism, combining Chartrain Platonism and Aristotelian dialectic with Victorine spirituality. Achard (abbot 1155–1160) also mingled Augustinian theology with Chartrain Platonism, but all the Victorines concurred in wishing to turn knowledge into wisdom and the reader of the profane sciences into a contemplative. They always returned to the internal and external experi-

ences of the soul, and frequently to the use of allegory and symbolism in the penetration of divine truths. In the early thirteenth century the influence of Pseudo-Dionysius, which had been powerful upon Hugh, prevailed again upon Thomas Gallus, who was a forerunner of the mysticism of the later Middle Ages.

David Luscombe (1967)

SALMON, WESLEY

(1925–2001)

The American philosopher of science Wesley Charles Salmon was born August 9 in Detroit, Michigan, and died April 22 near Madison, Ohio. He pursued undergraduate studies at Wayne University and the University of

Chicago Divinity School, received an MA in philosophy from the University of Chicago in 1947, and a PhD in philosophy from the University of California at Los Angeles in 1950. His principal academic appointments were at Brown University, Indiana University, the University of Arizona, and the University of Pittsburgh; he retired from this last institution in 1999. At UCLA his dissertation advisor was the philosopher of science Hans Reichenbach and much of Salmon's subsequent work was influenced by Reichenbach's philosophy. A lifelong defender of empiricism, Salmon made significant contributions to a wide range of topics, primarily in explanation, causation, inductive inference, and the philosophy of probability.

WORK

Beginning in 1971, Salmon developed a widely discussed alternative to Carl Hempel's covering law model of scientific explanation. The key element of Salmon's statistical relevance model was its insistence that explanatory factors must be statistically relevant to the occurrence of the event to be explained. This undermined in two ways Hempel's view that an explanation must lead people to expect the explanandum to occur. It showed that this condition was not necessary because events with low probability, such as the occurrence of lung cancer, can be explained in terms of statistically relevant factors such as cigarette smoking. It also showed that Hempel's model did not provide sufficient conditions for an explanation because irrelevant factors such as a man's taking birth control pills, when included in a Hempelian explanation, undermine the effectiveness of an explanation of his not getting pregnant.

In the course of developing the statistical relevance model, Salmon began to stress the importance of the causal relevance, rather than the statistical relevance, of explanatory factors; his 1984 book *Scientific Explanation and the Causal Structure of the World* contains an account of probabilistic causality grounded in an "at-at" theory of causation within which spatiotemporally continuous markable processes connecting cause and effect play a central role. The aim was to provide an account of causation free of appeals to counterfactuals and thus acceptable to an empiricist, yet different from Hume's in stressing the importance of connecting processes. In the light of criticisms that the markability criterion required tacit appeals to counterfactuals, Salmon abandoned it in the early 1990s and adopted a position where the transmission of conserved quantities was what distinguished causal from non-causal processes.

This appeal to causal processes and the distinction between genuine processes and pseudo-processes meshed with Salmon's interests in space-time theories. In that area he defended a causal theory of space and time within which the direction of time was to be grounded in causal asymmetries. He also maintained a long-term interest in conceptions of synchrony and in defending a conventionalist approach to simultaneity relations.

In his 1984 book, Salmon argued for a form of scientific realism based on the principle of the common cause. This principle states that if an association is observed between two types of event then, in the absence of a direct causal connection between instances of the events, there exists a common cause responsible for generating the association. This principle is general and can be used to argue for the existence of unobserved entities. It lies behind the reasoning used by Bertrand Russell in inferring the continued existence of a cat from its occasional observed appearances and was employed, Salmon claimed, by Jean Perrin in using the similarity of values obtained from different experimental techniques to determine Avogadro's number to argue for the reality of atoms. Despite its appeal, the principle does have its limitations. It is inapplicable in certain quantum mechanical situations where there are no hidden variables. It is also easy to find cases where two properties each increase over time but there is no common cause underlying the two. Nevertheless, Salmon's emphasis on this principle has led to an important new way of thinking about scientific realism.

Much of Salmon's early work concerned issues in probability and induction. For many years he defended Reichenbach's pragmatic vindication of induction, which argues that inductive inferences, more specifically the "straight rule" that projects the existing relative frequency of an event's occurrence into the future, is at least as likely to be successful as any other rule. In the light of criticisms by Ian Hacking, Salmon tempered his advocacy of this approach while continuing to insist on the importance of linguistic invariance for inductive rules.

Throughout his career Salmon defended a relative frequency interpretation of probability, including its use in his accounts of causation. For Salmon, the correct frequency to attribute to an event was the frequency within the broadest homogenous reference class to which the event belongs—that is, that class of events for which no further statistically relevant factors exist. Although he occasionally displayed sympathy for a propensity approach to probabilities and appreciated the role played by logical probabilities in Carnap's inductive logic, he

developed important criticisms of both. In many of his writings, Salmon argued that an objective form of Bayesian inference could illuminate a number of issues in the philosophy of science. Most notable, Salmon's insistence on preserving the context of discovery/context of justification distinction and on using Bayesian methods in the latter area led him to argue that Kuhn's account of theory choice could be made more objective by employing Bayesian techniques of theory justification.

In addition to his philosophical contributions, Salmon was an outstanding teacher and was much admired for his personal qualities. His introductory logic book was widely used as an undergraduate text, went into three editions, and was translated into five foreign languages. The exemplary clarity of his writing is evident in all of his publications.

SANCHES, FRANCISCO

(c. 1551–1623)

Francisco Sanches, a philosopher and physician, was born on the Spanish-Portuguese border, either in Tuy or Braga, of Marrano or New Christian parents. His family had moved to Portugal and then to southern France to escape religious and political persecution. The young Sanches studied at the Collège de Guyenne in Bordeaux, the same

school that his distant cousin, Michel Eyquem De Montaigne, attended. Sanches studied in Rome and then went to the University of Montpellier, where he received a degree in medicine in 1574. He was appointed professor of philosophy in 1585 and professor of medicine in 1612 at the University of Toulouse, where he had a successful career until his death in 1623.

One of Sanches's first philosophical writings that has survived is a letter to the Jesuit mathematician, Father Christopher Clavius, who had just edited Euclid's works and whom Sanches had met in Rome. Sanches offered a skeptical attack on the possibility of attaining genuine truth in mathematics. This was followed by his most famous writing, *Quod nihil scitur* (*That Nothing Is Known*). He soon thereafter wrote a critical examination of the astrological interpretations of the comet of 1577, *Carmen de Cometa*, published in 1578, and some commentaries on portions of Aristotle's writings, as well as many medical works. Sanches criticized various Renaissance naturalistic views, such as those of Girolamo Cardano, and may have actually debated Giordano Bruno in person in Toulouse.

In the letter to Christopher Clavius, Sanches attacked a form of the Platonic theory of knowledge. We cannot gain knowledge of things through mathematical study, because the objects studied by mathematics are not the natural, real ones encountered in human life. Rather, these objects are ideal, or maybe even impossible ones, such as points and lines. The mathematical relations that are demonstrated about such objects do not help explain anything in nature or experience, unless we happen to know independently that the experienced objects have mathematical properties, and also know that the principles of mathematics are in fact true. As far as we can tell, mathematics is just conjectural or hypothetical until we can independently determine the nature of things.

Sanches's *Quod nihil scitur* was written in 1576 and published in 1581. In it he develops his skepticism by means of a critique of Aristotelianism. He begins by asserting that he does not even know if he knows nothing. Then he proceeds to analyze the Aristotelian conception of knowledge to show why this is the case.

Every science begins with definitions, but definitions are nothing but names arbitrarily imposed upon things in a capricious manner, having no relation to the things named. The names keep changing, so that when we think we are saying something about the nature of things by means of combining words and definitions, we are just fooling ourselves. On the one hand, if the names assigned to an object such as man, such as "rational animal," all

mean the same thing, then they are superfluous and do not help to explain what the object is. On the other hand, if the names mean something different from the object, then they are not the names of the object. By means of such an analysis, Sanches worked out a thoroughgoing nominalism.

Sanches went on to examine the Aristotelian notion of science. Aristotle defines science as "disposition acquired through demonstration." But what does this mean? This is explaining the obscure by the more obscure. The particulars that one tries to explain by this science are clearer than the abstract ideas that are supposed to clarify them. The particular, Socrates, is better understood than something called "rational." Instead of dealing with the real particulars, these scientists argue about a vast number of abstract notions and fictions. "Do you call this science?" Sanches asked, and then replied, "I call it ignorance."

The method of Aristotelian science, demonstration, is next attacked. A demonstration is supposed to be a syllogism that produces science, but this involves a vicious circle rather than engendering any new information. To demonstrate that Socrates is mortal, one argues from "all men are mortal" and "Socrates is a man." The premises, however, are built up from the conclusion: the particular, Socrates, is needed to have a concept of man and mortality. The conclusion is clearer than the proof. Also, the syllogistic method is such that anything can be proven by starting with the right premises. It is a useless, artificial means, having nothing to do with the acquisition of knowledge.

Sanches concludes that science cannot be certitude acquired by definitions, neither can it be the study of causes, for if true knowledge is to know a thing in terms of its causes, one would never get to know anything. The search for its causes would go on ad infinitum as one studied the cause of the cause, and so on.

For Sanches, true science is the perfect knowledge of a thing—"SCIENTIA EST REI PERFECTA COGNITIO." Genuine knowledge is immediate, intuitive apprehension of all the real qualities of an object. Thus, science will deal with particulars, each somehow to be individually understood. Generalizations go beyond this level of scientific certainty, and introduce abstractions, chimeras, and so on. Sanches's scientific knowledge consists, in its perfect form, of experiential apprehension of each particular in and by itself.

Sanches showed that, strictly speaking, human beings were incapable of attaining certainty. The science

of objects known one by one cannot be achieved, partly because of the nature of objects and partly because of the nature of humankind. Things are all related to one another and cannot be known individually. There are an unlimited number of things, all different, so they could never all be known. And still worse, things change so that they are never in such a final or complete state that they can be truly known.

On the human side, Sanches devoted a great deal of time to presenting difficulties that prevent people from obtaining true knowledge. Our ideas depend on our senses, which only perceive the surface aspects of things, the accidents, and never the substances. From his medical information, Sanches was also able to point out how unreliable our sense experience is, how it changes as our state of health alters. The many imperfections and limitations, with which God has seen fit to leave us, prevent our senses and our other powers and faculties from ever attaining any true knowledge. The conclusion of all this is that the only truly meaningful scientific knowledge cannot be known. All that humans can achieve is limited, imperfect knowledge of some things that are present in their experience through observation and judgment.

Sanches's claim that *nihil scitur* is argued for on philosophical grounds, on a rejection of Aristotelianism and an epistemological analysis of what the object of knowledge and the knower are like. His totally negative conclusion is not the position of Pyrrhonian skepticism, the suspense of judgment as to whether anything can be known, but rather the negative dogmatism of the Academics. A theory of the nature of true knowledge is asserted, and then it is shown that such knowledge cannot be attained. The Pyrrhonists, with their more thoroughgoing skepticism, could neither assent to the positive theory of knowledge, nor to the definite conclusion that *nihil scitur*.

Sanches put forward a procedure, not to gain knowledge, but to deal constructively with human experience. This procedure, for which Sanches introduced the term, for the first time, of *scientific method*, "Método universal de las ciencias," consists in careful empirical research and cautious evaluation of observable data. In advancing this limited or constructive view of science, Sanches was the first Renaissance skeptic to conceive of science in its modern form, as the fruitful activity about the study of nature that remained after one had given up the search for absolutely certain knowledge of the nature of things.

Sanches was influential in his own day and throughout the seventeenth century. *Quod nihil scitur* was reissued several times up to 1665. Late in the seventeenth

century two refutations appeared in Germany. People have seen possible influences not only on Descartes, but also on Pierre Gassendi, Marin Mersenne, Spinoza, and Leibniz, among others, although it is hard to delineate his exact influence as different from that of Montaigne, Sextus Empiricus, Cicero, Charron and other available skeptical sources who were read by most intellectuals of the time. It may be that Sanches's formulation of the skeptical problem is closer to the modern idiom than that of any of his contemporaries, including Montaigne, and in terms of how philosophy developed, reads more like a precursor of Bacon or Descartes.

SANTAYANA, GEORGE

(1863–1952)

George Santayana, the philosopher and man of letters, was born in Madrid. His parents separated within a few years of his birth, and his mother went to live in Boston, Massachusetts, with the children of a previous marriage. Santayana grew up in Ávila under his father's care, but at the age of eight he joined his mother in Boston. He was educated at the Boston Latin School and at Harvard College. After graduating from Harvard in 1886, he studied in Germany for two years and then returned to take his doctorate at Harvard, for which he wrote a thesis on Rudolf Lotze. He subsequently joined the department of philosophy and remained a member of the Harvard faculty until 1912, when a small inheritance permitted him to retire. He lived in England for a number of years and then in Paris, but in 1925 he finally settled in Rome. During World War II, he took refuge in the convent of an order of English nuns in Rome, and he continued to live there until his death.

CULTURAL BACKGROUND

Both Santayana's personal life and his philosophical development were decisively influenced by his peculiar position as a Spanish Catholic living and teaching in a predominantly Protestant society with a philosophical and cultural tradition that he felt to be in many respects deeply alien to his own personality. He was always proud—rather defiantly so—of his Catholicism and his Latinity, despite the fact that he was not a believer and was not notably attached to Spain or to Spanish culture. These loyalties expressed instead a deeply rooted hostility to the commercial and democratic ethos of modern industrial society and an equally deep aspiration toward a radically different style of life and thought that, for Santayana, was best exemplified in the classical Mediterranean world. Philosophically, he felt his truest affinities to be with the Greeks and perhaps the Hindus, and among the moderns, with Benedict de Spinoza, rather than with the empiricism and idealism of German and Anglo American philosophy. In fact, however, his points of affiliation with the European and American philosophy of the modern period are both numerous and obvious, and it would appear that his debt to the post-Cartesian tradition in modern philosophy is much

greater than he was inclined to think. What chiefly set his work apart from the mainstream of twentieth-century philosophy was his highly personal and literary mode of writing and his rather disdainful lack of interest in the methodological questions that were of central importance to the development of phenomenology on the Continent and analytic philosophy in the English-speaking world. When one considers the substantive doctrines to which he was committed, however, and, in particular, the ontological distinctions on which his “Realms of Being” rest, his philosophy emerges as a highly idiosyncratic doctrine of transcendental subjectivity that would scarcely be conceivable apart from the very tradition of modern philosophy which he so violently criticized.

PHILOSOPHICAL DEVELOPMENT

Santayana's philosophical career falls naturally into two main periods. The first of these is the period in which he published *The Sense of Beauty* (1896) and *The Life of Reason* (1905–1906); its chief distinguishing feature is Santayana's disposition at that time to conceive of philosophy as a kind of descriptive psychology of the higher mental functions. He assumed the broad truth of the doctrine of biological evolution and its relevance to the understanding of mental phenomena, and while he held all knowledge to be representational in nature, he did not question “our knowledge of the external world,” nor did he feel the need for any initial withdrawal of belief in such a world in the Cartesian manner. “Mind” is placed firmly in its biological context, and such independence as it enjoys is due not to any special ontological status, but rather to its capacity for giving an ideal and aesthetic meaning to its natural setting and functions.

In the second period, during which he wrote *Scepticism and Animal Faith* (1923) and *Realms of Being* (1927–1940), Santayana came to feel the need for a greater systematic rigor in the exposition of his views and for a purified and nonpsychological mode of stating the fundamental distinctions on which his philosophy rested. In particular, he felt that in *The Life of Reason* he had not made clear enough that the “nature” described there as having been “drawn like a sponge, heavy and dripping from the waters of sentience” was the idea of nature, not nature itself. He now tried to correct this error by means of a set of ontological—that is, nonpsychological—distinctions between the different kinds of being that are the objects of different kinds of mental activity. Thus, imagination, for example, must be defined by reference to the essences or abstract characters that Santayana now recognized as having a distinct ontological status, rather than

the other way around. In carrying out this revision of his earlier views, Santayana was in some measure aligning himself with similar antipsychologistic tendencies at work in the logical realism of Bertrand Russell, as well as in the phenomenology of Edmund Husserl, which he regarded as having a certain affinity to his own views.

Some commentators have felt that this shift from what they describe as Santayana's earlier naturalism to his later "Platonism" amounted to a fundamental change in his general philosophical perspective. Santayana's own statements, however, make it clear that the system presented in *Realms of Being* is to be understood as the ultimate philosophical basis of the naturalistic *Weltanschauung* sketched out in *The Life of Reason*, in which he had paid relatively little attention to technical philosophical issues. It must be admitted that the moral atmosphere of the two works differs, and that in the later one Santayana seems even more the detached spectator of the noncontemplative phases of the "life of reason" than he had before. But this is as much a personal as a philosophical matter, and there is no good reason for denying the fundamental unity of Santayana's thought during the two main periods of its development.

AESTHETICS

Santayana's first important philosophical work was *The Sense of Beauty* (1896). In it he attempted to state a complete aesthetic theory, which he later developed further in *Reason in Art* (1905), Volume IV of *The Life of Reason*. In the earlier book, aesthetic theory is characterized as a psychological inquiry whose data are aesthetic judgments considered as "phenomena of mind and products of mental evolution"; the inquiry is to be distinguished both from the actual exercise of critical judgment and from the historical investigation of the evolution of the various art forms. Santayana argued that this inquiry must be carried out independently of metaphysical issues and the "interests of the moral consciousness," and that it must make clear the bases of aesthetic experience in human nature as conceived by natural science and in particular evolutionary biology. To this end, Santayana sketched out a theory of value according to which all preference is an essentially irrational expression of vital interest and the standard of value is the enjoyment or pleasure procurable through different courses of action. Morality is concerned with negative values, namely, the avoidance of pain and suffering, while aesthetic value is concerned with positive enjoyment and stands in the same relation to morality as play does to work.

The pleasure that is distinctively aesthetic, however, must be further qualified as intrinsic (or immediate) and as "objectified," in the sense of being experienced as a quality of a thing and not as an affection of the organ which apprehends it. Santayana denied that it must have the disinterested character attributed to it by Immanuel Kant and that it must be universally shared. He defined beauty as "pleasure objectified."

MEDIUM, FORM, EXPRESSIVENESS. Santayana added to this definition of beauty a threefold distinction between the materials of a work of art, its form, and its expressiveness. Of these, the first two are intrinsic features of the work of art, which thus consists of sensuous elements that have varying degrees of aesthetic value by themselves, and a form or arrangement by means of which these elements are unified and which has its own distinctive value. This synthesis, which constitutes form, is "an activity of the mind." While Santayana throws out suggestions as to how the nature of our perceptual apparatus may determine *which* forms give pleasure, these suggestions are never developed, and there is a heavily mentalistic cast to his whole account of aesthetic experience. This is particularly true of his treatment of expression, which is the power of a work of art to suggest images and ideas that, by becoming associated with it, enhance its value. These associated values may be aesthetic, practical, or moral; or they may be intellectual, as they are in the case of those forms of art, for example, tragedy, which present the ugly as well as the beautiful, and whose value thereby consists in satisfying our desire to know life as a whole. In the end, however, while these distinctions of materials, form, and expression have the validity proper to their spheres, the experience of beauty remains, according to Santayana, unique and unanalyzable.

FUNCTION OF ART. In *Reason in Art* Santayana was concerned with the place of art, as one good among many, within the moral economy of the life of reason. He distinguished between the practical arts and the fine arts and explained the emergence of the latter from the former through the gradual growth of an appreciation of the intrinsic value of what originally had merely instrumental value. Applying this principle, Santayana described the development of music, poetry, and the plastic arts, and in each case attempted to relate the special features of the artistic medium to the mode of abstraction and selectivity that is peculiar to a given art form. He treated all works of art as more or less abstract symbolizations of the natural environment and interests of human beings, and as being animated by an internal "dialectic" of their own

through which the moral and dramatic unities of our experience are indirectly expressed. There can be no absolute or universal principles for criticizing works of art, since our critical judgments are simply the corrections or modifications that our aesthetic preference undergoes in the wake of experience; and there is no a priori guarantee that these corrections must be convergent. The ultimate justification of art is simply that it adds greatly to human enjoyment, and thus to human happiness.

THE LIFE OF REASON

Santayana intended *The Life of Reason; or The Phases of Human Progress* (1905–1906) as a naturalistic biography of the human mind, but as he himself pointed out, it was at least partially inspired by G. W. F. Hegel's *Phenomenology of Mind*. What appealed to Santayana in that work and similar ones in the idealistic tradition was the idea of sympathetically espousing the changing perspectives—scientific, moral, religious, and aesthetic—by which the mind progressively defines its relationship to its natural milieu. By beginning with *Reason in Common Sense*, he hoped to avoid the fundamental error of the idealists, which was to lose all sense of the dependency of this evolution upon a nonmental nature and of its responsiveness to the strains and stresses of our animal being. For the fraudulent dialectical necessity that Hegel had imposed on human history, Santayana proposed to substitute an appraisal—in the broad sense, a moral appraisal—of the contribution made by each of these phases of human development to the ideal of a rational and happy life.

REASON AND IMAGINATION. In *Reason in Common Sense*, the discovery of natural objects is described as the first and irreversible achievement of human reason operating upon the materials of sense experience. Knowledge of these objects is inevitably representative and indirect, and the relationship of thought to reality must be conceived as an ideal correspondence and not as a material appropriation. Coordinate with these “concretions in experience” are “concretions in discourse,” or concepts which sustain among one another all manner of “dialectical” relationships; and the active elaboration of these is the generic activity of imagination. Imagination becomes understanding when, almost by accident, some of its structures prove to be faithful transcriptions of a sequence of natural events; but even when the understanding is most successful, there remain unassimilable traits of experience which, at best, have a tangential relation to the natural order.

Toward the free creative activity of the imagination itself, Santayana maintained a dual attitude. It must not, he said, be allowed to impose itself as a literal rendering of what exists, as it all too often attempts to do. When it is allowed to do so, it can only produce a fantastic physics in which dramatic and moral unities are substituted for unities of fact and real process. In another sense, however, the life of reason is the life of the imagination, and its function of idealization and symbolic transformation yields the highest and purest enjoyments of the mental life. Even when the imagination becomes practical, as it does in science, it is the intrinsic aesthetic value of its creations, and not their ulterior practical use, which gives them a place within the life of reason. But at the same time that he praised the imagination, Santayana continually warned against the tendency to confer substantial reality upon the essences it elaborates and to assign to them a causal efficacy within the order of nature. The only power that Santayana was willing to attribute to consciousness itself was that of conferring meaning and ideal unity upon events, and it is in this sense that he described himself as being a materialist.

RELIGION. If Santayana's theory of the imagination finds its most natural application in his treatment of art, an area in which the claim to any literal validity is reduced to a minimum, the case of religion, which he considers in *Reason in Religion*, Vol. III of *The Life of Reason*, is somewhat different. Religion, Santayana said, is a poetic transformation of natural life in the interest of the moral ordering of that life, even though each religion is typically regarded by its followers as embodying a literal truth. Religion is myth, and it presents “an inverted image of things in which their moral effects are turned into their dramatic antecedents.” Because it is myth, religion must not be judged by the inappropriate standard of literal truth, but on the basis of the imaginative richness and comprehensiveness of its reorganization of our moral experience. One's religion is in fact something like one's language or nationality—a native idiom of the moral life which may have its imperfections, but which is both difficult and unwise wholly to abandon. Mystical religions are those that effect vast simplifications of the moral life by excluding all but one element in the natural life, while fanatical religions are those that suppress, on the authority of their own unique truth, all forms of moral poetry other than their own. In Santayana's view, both are inimical to the true value of religion, which is the encouragement it gives us to live in the imagination. True religion stimulates both piety, which Santayana defined as “man's reverent attachment to the sources of his being and the

steadying of his life by that attachment,” and spirituality, which liberates us from the harsh realities of animal need and desire by interposing an ideal meaning—one that assigns to the goods of this world their proper and subordinate place.

What is paradoxical in Santayana’s philosophy of religion is the fact that while he treated all religions as having, at best, a symbolic or expressive truth, he severely condemned the liberals and “modernists” who have attempted, while remaining within the church, to substitute for the literalistic dogmatism of the past a view of religion that in many respects resembles the one held by Santayana himself. It seems inconsistent to deny that a claim to literal truth is essential to religion and at the same time to require that those who surrender this claim must leave the church. This is perhaps a special case of a general paradox resulting from the fact that while Santayana declared “spirit” to be wholly inefficacious, it is an intrinsic feature of the life of reason that spirit should view itself as having efficient power. One may also speculate as to whether Santayana’s distaste for views resembling his own, when they become more than the private insights of detached and passive observers and are applied to the task of modifying some institution such as a church, did not itself express a social attitude and a partisanship that cannot claim any special philosophical justification.

SOCIAL THEORY. Santayana’s theory of society is stated in *Reason in Society*, Volume II of *The Life of Reason*, and also, in expanded form, in *Dominations and Powers* (1949), his last major work. In the main, social life is assigned a subordinate role within the life of reason. Its principal task and justification is the generation of, and care for, human beings, and it serves ideal ends only incidentally. Society originates in the reproductive instinct, and while this instinct lends itself readily to imaginative development, it finds its ultimate fruition in institutions (the family, the army, the state) that are predominantly practical in nature and, at best, capable of a retrospective idealization. It is, of course, possible for individuals to become associated with one another outside the disciplinary framework of these primary institutions, and when they do so freely, on the basis of a common allegiance to an ideal, they form what Santayana called a “free,” or “rational,” society. Patriotism is the loyalty they feel to such societies; but the deepest loyalties of the life of reason are not to anything actual, but to the ideal presences of which, Santayana said, our human partners in the pursuit of the ideal, as well as we ourselves, are at best imperfect symbols. Thus it turns out that the true society—the

only society that is a perfect instrument of the life of reason—is the society of the mind and of the essences it entertains.

If Santayana’s theory of society expresses, as indeed it does, a profound lack of interest in the practical concerns by which any human society is principally animated, he was nevertheless not without his own strong preferences with regard to a certain ordering of society. A pervasive animus against democracy and liberalism runs through all his discussions of society and is perhaps most noticeable in *Dominations and Powers* (1949). Human society, Santayana argued, is necessarily aristocratic and hierarchical, and egalitarian democracy, which would put an end to the injustice that social inequality so often generates, succeeds only in destroying the interest of life by denying or attempting to suppress our inevitable human diversity. An authentic and “natural” aspiration to some good expresses itself in the form of an authoritative direction of the more passive members of a society and shapes their lives in the light of this aspiration’s own moral vision. Accordingly, Santayana frequently tended to identify strong authoritarian government with the natural bent of a self-assertive vitality and uniformly treated liberalism as an incoherent and sterile principle of dissolution, roughly comparable in its inspiration and effect to the Protestant principle in the province of religion. Both liberalism and the Protestant principle are expressions of that romantic individualism that Santayana was willing to tolerate as a kind of playful self-deception of the “inner life,” but which he abominated whenever it took itself seriously and became a principle of action directed toward correcting the “natural” order of things.

MORALITY. Strangely enough, it is in *Reason in Science*, Volume V of *The Life of Reason*, that Santayana’s fullest exposition of his views on morality is to be found. In this work he distinguished between “rational” morality and the morality that is either “prerational” or “postrational.” Rational morality is no longer the straightforward hedonism of *The Sense of Beauty*, for Santayana now recognized that there must be a principle of selective preference among possible enjoyments. But he still regarded our adoption of such an ideal standard as a matter of temperament and natural inclination; and even the attempt to achieve a comprehensive integration of diverse satisfactions, which is what distinguishes rational morality, is presented as just one possible attitude toward life. Rational morality and the moral philosophy associated with it, Santayana argued, are concerned with what is really good, and they require a highly developed capacity for sympathetic understanding and assessment of all

competing goods; but in the end, what is really good can only be what genuinely expresses some vital bias of our natures. By contrast, prerational morality is the unreflective life of primary impulse, which cannot conceive the possibility of alternative goods nor support the discipline entailed by a principled organization of the moral life. Postrational morality, finally, is an essentially religious abandonment of the hope for a rational ordering of human life in favor of some otherworldly ideal. Its sole strength, as Santayana observed, lies in the remnant of natural assertiveness that survives in its condemnation of the works of the natural man and the desperate energy with which a single and exclusive regimen of life is proclaimed to be the sole means of salvation.

SCIENCE. Santayana's attitude toward science, as one phase of the life of reason, was an inconsistent mixture of hospitality and indifference. Convinced as he was that all causal efficacy belongs to physical nature, he was strongly inclined to accept the claim of science to exclusive authority in the determination of what is really true. Natural science is at once an extension of common sense and a uniquely successful application of "dialectics," that is, the logical elaboration of terms of thought, or "concretions in discourse," to the study of the physical world. The ideal of such a science would be a closed, mechanistic, and materialistic system, and Santayana believed that progress in the sciences of man, notably psychology, required the adoption of this ideal. But beyond this recognition of the authority of science, Santayana had no detailed interest in its findings and only a very limited belief in its power to contribute to those ideal values that are the true substance of the life of reason. It deals, after all, with only one of many possible worlds; and while the discipline of fact to which it subjects the mind is infinitely preferable to the projection upon the world of some moral fable of our own devising, the highest form of intellectual freedom is still to survey the field of ideal possibilities without any sense of an obligation to describe or a fear of misdescribing any actual state of affairs.

SCEPTICISM AND ANIMAL FAITH

In *Scepticism and Animal Faith* (1923), Santayana undertook the extensive recasting of his whole system of thought; to which reference has been made above. The reformulation was to consist in the substitution of a set of ontological distinctions for the introspective psychology of his earlier writings. Properly speaking, this work is an introduction to, and a partial summary of, the main doctrines of *Realms of Being* (1927–1940). It begins with an attempt to radicalize, and thus to overcome, the idealistic

skepticism concerning the existence of an external world that has been a central theme of Western philosophy since René Descartes. The argument is that if we limit ourselves to what is immediately given (and therefore incapable of being doubted), not only our belief in an external world, but also our belief in the existence of the self, of other selves, and of a past and a future is undermined. All that remain are certain characters or essences that bear no relationship to things or events and cannot properly be said to "exist."

Santayana's point is that a genuine skepticism, pushed to its logical extreme, is just as fatal to the "mind" of the idealists as it is to the matter they were prepared to abandon. In a positive sense, the upshot of such skepticism is to reveal essence as the primary and incontestable mode of being; but it is practically and psychologically impossible for human beings to recognize only essential being. "Animal faith" thus supervenes upon the intuition of essence and posits the existence of a world of things and events that transcends immediate intuition. In one sense this belief is quite baseless, since there cannot, in a strict sense, be proof that anything exists; but in another sense this belief is the beginning of wisdom. In this conception there is no great shift away from the view set forth in *The Life of Reason*. The chief difference, however, is that in *Scepticism and Animal Faith* the commitment to existence and to substance (which in the earlier work was presented retrospectively as the first great achievement in the history of consciousness) is first dramatically revoked and then reinstated by the individual mind. But with respect to the logical status and practical necessity of this belief, Santayana's views would not appear to have undergone any significant change.

THE REALMS OF BEING

The Realms of Being is a detailed characterization of the four major modes of being or basic categories that emerge from the skeptical self-interrogation of consciousness. The modes of being consist of essence and matter, as noted above, and two derivative modes, truth and spirit.

ESSENCE. The being of essence is first carefully distinguished from certain adventitious notions that have been associated with it in the history of Western philosophy. Among these are the views that attribute causal efficacy or some special moral or aesthetic status to essences as such, and also the views that envisage essence only in the context of some mental activity such as "abstraction" or "imagination." Properly conceived, the being of essence

consists simply in the self-identity of its character. Since this intrinsic character involves no reference to any location in space or time, essences are universal and repeatable. They are infinite in number and yet collectively compose one absolute essence in “Pure Being,” which is common to all essences. Essences are logically discrete and individual, and one essence can “imply” another only if it is first stipulated that the relationship is that of a whole to one of its parts and that no logical necessity governs the constitution of such wholes. Essences may be exemplified in the realm of matter, but they need not be; and even when they are, the things and events that are the bearers of these ideal characters have a quite different mode of being.

MATTER. The “indispensable properties” of the material mode of being are spatial extension and temporal process. Matter exists contingently and is therefore unstable and evanescent; but it also maintains a dynamic continuity, through change and can in this sense be called “substance.” It is external to and independent of consciousness; and it is ultimately unknowable, since we know it only through the essences it exemplifies—and these are radically incapable of representing the element of process and diffusion that is peculiar to the realm of matter. Organisms are part of that realm, and the psychological histories (as distinct from the pure consciousness) of human beings can be understood only by reference to the behavioral unity that Santayana calls the “psyche.”

TRUTH. Originally, Santayana had intended to establish only three “Realms of Being,” and in fact the Realm of Truth that he later added has obvious affinities with both essence and matter. Truth is the truth about matter, or what exists, and yet it is independent of existence both because “no fact can be a description of itself” and because even if nothing existed, it would still be true that nothing did exist or that just such and such things had existed in the past. Truth is “the sum of all the propositions,” and as such it represents a certain selection from the infinite essences or character that things might have had. Truth is timeless and independent of all beliefs. There are no necessary truths, and even the propositions of mathematics are only contingently true since it is simply an accident if they correctly describe the material world.

SPIRIT. Spirit, as Santayana used the term, is simply pure transcendental consciousness, and as such it must be distinguished from its physical basis (the “psyche”) and from particular mental events. The only criterion of the exist-

tence of spirit is internal; and it exists contingently. It is entirely passive in its relation to physical nature, and its sole function is pure intuition, which, Santayana says, is “the direct and obvious possession of the apparent without commitments of any sort about its truth, significance, or material existence.” The unities of intuition are simply individual essences and are not the product of any mental machinery. By itself, intuition is not cognitive. Considered simply as a skein of meanings, the life of intuition may acquire a unity and a life and even a kind of freedom that lacks the power to intervene in the world but is nevertheless the highest and purest human good.

To some extent, *The Realms of Being* effects a clarification of Santayana’s earlier views, although it may be doubted whether he was ever in much danger of being taken for an idealist. Unfortunately, the style of the later book is even more luxuriant than that of *The Life of Reason*, and Santayana’s unwillingness to argue technical philosophical issues was still as strong as ever. If what he hoped to present in *Realms of Being* was, as he says, a language in which the great distinctions to which we all have recourse would be clearly marked out, his success must be judged to be only very partial. All doctrines of transcendental subjectivity, including Santayana’s, engender immense difficulties which cannot be resolved unless the philosopher is more inclined to meet criticism on some ground other than the assumed truth of his own views. In *Realms of Being*, there are very few signs, of such a disposition on Santayana’s part.

CRITICAL WORKS

Santayana was not just a philosopher in his own right but also a critic, both philosophical and aesthetic. Several of his books, among them *Interpretations of Poetry and Religion* (1900), *Three Philosophical Poets* (1910), *Winds of Doctrine* (1913), *Character and Opinion in the United States* (1920), *Platonism and the Spiritual Life* (1927), and *Obiter Scripta* (1936), are made up of critical studies of systems of thought as diverse as the pragmatism of William James and the atomism of Lucretius; and in many ways, Santayana was at his best as a critic; and in many ways, Santayana was at his best as a critic. In spite of the severity of his judgments and his tendency to use both philosophers and imaginative writers as stalking horses for his own philosophical purposes, he seldom failed to make some telling observation or incisive criticism that had a validity independent of his own special point of view. At the same time, it must be noted that in his critical essays he too often affected an Olympian manner that only partially concealed the strongly personal

character of his tastes and distastes both for individuals and ideas.

Bibliography

WORKS BY SANTAYANA

Major Philosophical Works

The Sense of Beauty. New York: Scribners, 1896.

The Life of Reason; or The Phases of Human Progress. 5 vols.

New York: Scribners, 1905–1906; 1 vol. ed., New York, 1954.

Scepticism and Animal Faith. New York: Scribners, 1923.

Realms of Being. 4 vols. New York: Scribners, 1927–1940; 1 vol. ed., 1941.

“Three Proofs of Realism.” In *Essays in Critical Realism*. New York, 1941.

Dominations and Powers. New York: Scribners, 1949.

Critical Writings

Interpretations of Poetry and Religion. New York: Scribners, 1900.

Three Philosophical Poets. Cambridge, MA: Harvard University Press, 1910.

Winds of Doctrine. New York: Scribners, 1913.

Egotism in German Philosophy. New York: Scribners, 1915.

Character and Opinion in the United States. New York: Scribners, 1920.

Platonism and the Spiritual Life. New York: Scribners, 1927.

Some Turns of Thought in Modern Philosophy. New York: Scribners, 1933.

Obiter Scripta, edited by J. Buchler and B. Schwartz. New York: Scribners, 1936.

The Idea of Christ in the Gospels. New York: Scribners, 1946.

Other Works

The Last Puritan. New York: Scribners, 1936. Santayana’s only novel, which is also a “memoir” of considerable interest.

Persons and Places. 3 vols. New York: Scribners, 1944–1953. Autobiography.

The Letters of George Santayana, edited by Daniel Cory. New York: Scribners, 1955.

WORKS ON SANTAYANA

Duron, Jacques. *La pensée de George Santayana*. Paris: Nizet, 1950. A massive and detailed study of Santayana’s whole philosophy.

Howgate, George W. *George Santayana*. Philadelphia: University of Pennsylvania Press, 1938. A less technical study of Santayana, mainly as a critic and aesthetician.

Munitz, Milton. *The Moral Philosophy of Santayana*. New York: Columbia University Press, 1939.

Schilpp, P. A., ed. *The Philosophy of George Santayana*. Vol. II in the Library of Living Philosophers. Evanston, IL: Northwestern University Press, 1940. A collection of critical

essays by a group of philosophers, among them Bertrand Russell, with an autobiographical statement by Santayana, a detailed reply to his critics, and a detailed bibliography. The most useful single work on Santayana’s philosophy.

Singer, Irving. *Santayana’s Aesthetics*. Cambridge, MA: Harvard University Press, 1957.

Frederick A. Olafson (1967)

SARTRE, JEAN-PAUL

(1905–1980)

Jean-Paul Sartre, French existentialist philosopher and author, was born in Paris where he attended prestigious *lycées* and then the *École Normale Supérieure* from 1924 to 1928. After passing his *agrégation* the following year, he taught in several *lycées* both in Paris and elsewhere. In 1933, he succeeded Raymond Aron (1905–1983) as a research stipendiary for a year at the Institut Français in Berlin, where he immersed himself in phenomenology, concentrating on Edmund Husserl but also reading Max Scheler and some Martin Heidegger. In the years following his return to France, he published several phenomenological works as well as the philosophical novel *La nausea* (*Nausea*) (1938) that brought him public recognition. He resumed his teaching till conscripted into the French Army in 1939. After serving ten months as a prisoner of war chiefly in Trier, where he taught Heidegger’s *Being and Time* (1962) to several imprisoned priests and continued writing his masterwork caps for *L’être* (*L’être et le néant*) (Being and nothingness) (1943), he returned to Paris for three more years of *lycée* teaching. Soon he was able to make his living from his writing and would never teach again. He was involved in a short-lived resistance movement of intellectuals that included Maurice Merleau-Ponty and Simone de Beauvoir, the latter his lifelong companion. With these and several others, he founded the journal *Les temps modernes* (Modern times), its first issue appearing in October 1945, which quickly became the voice of existentialism and remains a leading literary and political publication to this day.

In the aftermath of the war, Sartre emerged as the leader of the existentialist movement, the quasi manifesto of which he delivered in a famous address subsequently published as *L’existentialisme est un humanisme* (1946). By then, he was world famous. He used his celebrity to promote political and social causes of the Left in accord with the theory of *committed literature* introduced in a series of essays published as *Qu’est-ce que la littérature?* (What is literature?) in *Les temps modernes* (1947). He wrote a number of short stories, novels, and plays as well

as several studies of the lives of famous authors, including his autobiography, *Les mots* (The words), for which he was awarded the Nobel Prize in Literature (1964) and which he declined. After an unsuccessful association with an incipient noncommunist nonparty of the Left, he abandoned organized politics. His relations with the Communist Party ran hot and cold. Initially vilified by the party as a bourgeois individualist, he gradually became a fellow traveler, using different standards with which to judge the East and the West during the Cold War. But after the Soviet occupation of Budapest in 1956 and the crushing of the Prague Spring in 1968, he turned against the French Communist Party and moved farther Left, titling one interview: “*Les Communistes ont peur de la révolution*” (The Communists are afraid of revolution) (*Situations*, VIII, 1969). In 1960 he published his second major philosophical work, the first volume of *Critique de la raison dialectique, précédé de questions de méthode* (The critique of dialectical reason) preceded by a kind of preface *Questions de méthode* (Search for a method) that had appeared in *Les temps modernes* in 1957. This marked his theoretical shift from a philosophy of consciousness and subjectivity to one of dialectical praxis (human activity in its socioeconomic milieu). Many see this as the theoretical basis for the student revolt known as *the events of May, 1968* that constituted a turning point in French cultural life.

Throughout these years of political turmoil and despite his proclaimed abandonment of imaginative literature in favor of political action, Sartre continued to labor on his multivolume study of Gustave Flaubert’s life and times, *L’idiot de la famille; Gustave Flaubert de 1821–1857* (The family idiot: Gustave Flaubert de, 1821–1857) (1971–1972). After a number of strokes in the 1970s left him almost totally blind, he began a series of interviews with former Maoist activist Benny Lévy (1945–2003), then serving as his secretary, that he announced would leave none of his earlier positions unchanged. The proposed elements of an *ethic of the ‘We’*, as he called it, appeared in three issues of the weekly magazine *Le nouvel observateur*. Titled “*L’espoir maintenant*” (Hope now) these interviews constitute his last publication during his lifetime. After his death on April 15, 1980, the funeral cortege was joined by thousands of people in the largest spontaneous demonstration Paris had seen since the death of France’s president Charles De Gaulle (1890–1970). France had lost “the conscience of his time,” proclaimed the lead essay in a major journal (*Magazine littéraire*, September 1981) and the immense crowd of mourners seemed to agree.

A PHILOSOPHER OF THE IMAGINATION

Starting with his thesis for the diplôme d’études supérieures titled “The Image in Psychological Life: Role and Nature” (1926) Sartre exhibited a strong interest in the realm of the imaginary. This becomes the object of two of his early publications, *L’imagination* (1936), a reworking of the earlier thesis, and the more important *L’imaginaire* (The imaginary) (1940), in many ways the key to his subsequent thought. For what he attributes to imaging consciousness in the latter—namely, that it is the locus of possibility, negativity, and lack—is precisely how he will later characterize being-for-itself or consciousness in *Being and Nothingness*. Imaging consciousness becomes the paradigm of consciousness in general for Sartre.

From this follow several characteristic features of his aesthetics, ethics, and political theory as well as the *choice* of the imaginary on the part of the subjects of his existentialist biographies or *psychoanalyses*. It also explains the ease with which he employed the method of *free imaginative variation of examples* (eidetic reduction) from Husserlian phenomenology in constructing his philosophical position. Many of his *arguments* are descriptive in nature, exhibiting Husserl’s remark that the point of phenomenology is not to explain but to get us to *see*. Moreover, the matching of imaging consciousness with conceptual analysis in Sartre’s works serves to bridge the commonly perceived distance between philosophy and imaginative literature, helping us better appreciate the philosophical approach to literature and the literary approach to philosophy that mark his writings. His novel *Nausea*, for example, anticipates, and his play *No Exit* (1944) applies, theses and themes of *Being and Nothingness* in concrete fashion.

Sartre remained faithful to the descriptive method of phenomenology throughout his career. Even when he introduced the dialectical *progressive-regressive* method in *Search for a Method*, it was to be preceded by a phenomenological description of the situation at hand. But he was not an uncritical reader of Husserl. In a major essay, “Transcendence of the Ego,” composed while in Berlin but published in 1937, Sartre defends what Aron Gurwitsch called a *nonegological conception of consciousness*. The *of* in the title denotes both a subjective and an objective genitive: The transcendental ego of Husserlian phenomenology has been rendered unnecessary (transcended) whereas the empirical ego (the subject of our reflective knowledge and scientific study) *transcends* consciousness in the sense that it is *other* than the conscious-

ness one has of it. This allows Sartre to distinguish between an autonomous, *prereflective* consciousness that is impersonal or *prepersonal* and the realm of reflective awareness that constitutes our psychological life, which he will call the *Psyche*. He wrote a lengthy manuscript on the latter, only a portion of which was ever published—*Esquisse d'une théorie des émotions* (Sketch for a phenomenological theory of the emotions) (1939).

One of the core theses of phenomenology is the claim that all consciousness is consciousness of an other-than-consciousness. Consciousness simply is this aiming at or *intending* an object. This is Husserl's famous thesis of *intentionality* as the defining characteristic of the mental. Perhaps no other phenomenologist has pursued the thesis of intentionality with such consistency as Sartre, even to the point of accusing Husserl, rightly or not, of having betrayed this principle by his understanding of mental images as simulacra *inside* the mind. Sartre will insist that if images are conscious, then they, too, are ways of intending the world as are our emotions. The challenge is to articulate the distinguishing features of these various ways of being *in-the-world*, an expression Sartre adopts from Heidegger.

In *The Imaginary* Sartre undertakes the task of describing the defining characteristics of the image. Relying on the evidence from his reflective description of our prereflective awareness, he identifies four essential features of the image:

1. *The image is a consciousness* rather than an object *inside* consciousness (Sartrean consciousness has no inside; it is essentially *outside*, in-the-world). The image is a relationship to an object. Hence, it is more accurate to speak of *imaging consciousness* than of *images*. The latter term suggests miniatures that we project outside the mind, an example of what Sartre terms *the illusion of immanence*, which is contrary to the intentionality of consciousness.

2. In contradistinction to perception, which must grasp its object in *profiles* that it synthesizes into a perceptual judgment of identity (these are profiles of one and the same cube that cannot all be given simultaneously) imaging consciousness presents its object all at once (we see in the object only what we place there; the image teaches us nothing). Whereas the perceived object *overflows* our perception of it and invites further investigation, in the case of imaging consciousness, what you imagine is what you get. The *studying* of an imagined object is actually the sequential *viewing* of a series of imagings. Sartre calls this the phenomenon of *quasi-observation*. I can syn-

thesize the series into the object of flesh and blood (my friend Peter, for example) that I could perceive, were he available for perception, but ex hypothesi, as imagined, he is unavailable.

3. *Imaginative consciousness posits its object as a nothingness*. Sartre describes this as making its object *present-absent*, that is, present but out of the circuit of my perceptual beliefs that define the *real*. The realm of the imaginary is what Sartre designates the *irreal* as distinct from the *unreal*, which could apply to the perceptual or the conceptual realm. Following Husserl, Sartre allows for just four types of presence-absence: One can imagine the object as nonexistent (unicorns), as absent (Peter as not here), as existing elsewhere (Peter in Berlin), or in a neutral mode that simply prescind from its existence (as with ideal objects, for example). This is what distinguishes my awareness of the imagined tree from that of the perceived one, which is grasped as present in its *materiality*. Sartre will elaborate this *nothingness* when he describes the *othering* or *nihilating* nature of consciousness in general in *Being and Nothingness*.

4. Imaging consciousness is *spontaneous*, another feature that Sartre will later extend to consciousness sans phrase. This characteristic denotes the prereflective and implicit (Sartre calls it *nonthetic*) awareness that imaging consciousness has of its creative power as it sustains the object in presence-absence. Sartre will speak of this as an awareness of freedom, which he already extends to prereflective consciousness across-the-board and which he will later liken to Descartes's notion of God's power to conserve in existence the created world.

Much of Sartre's aesthetic theory turns on this idea of the image, which he defines as: "an act that aims in its corporeality at [intends] an absent or nonexistent object, through a physical or psychic content that is given not as itself, but in the capacity of analogical *representative* of the object aimed at [intended]" (Sartre 1940/2003, p. 22). As intentional, consciousness has no contents but it does have objects. In the case of aesthetic objects such as the portrait of Charles VIII or the playing of the Appassionata Sonata, the artifact, say the physical painting or the musical performance, serves as *analogon* for the creative imagination of artist and public alike. By our assuming the *aesthetic* attitude, that is, by *derealizing* the perceptual object, the artifact serves as analogon for making present-absent (re-presenting) this particular aesthetic object. Sartre emphasizes that the imaging act is a synthesis of cognitive and emotional intendings. But his analysis

attends chiefly to the primary role of imaging consciousness in this *derealizing* act.

To indicate the pervasiveness of imagination in Sartre's thought, it suffices at this point to mention the role reserved in his existentialist ethic for the *image* of the kind of person I want to be that is implicit in my moral choices, a clear reference to the phenomenological ethics of Scheler. Nor should we overlook the guiding ideal of the *City of ends* throughout Sartre's political philosophy. And when we recall its character as the locus of negativity, possibility, and lack, the presence of the imagination appears as far-ranging as consciousness itself.

AN ONTOLOGIST

Sartre remarked late in his career that what distinguished him from the Marxists was that he raised the class question starting with being, which is wider than class, whereas they do not. He elaborates his ontology in two major works.

BEING AND NOTHINGNESS. The subtitle of *Being and Nothingness* is "A Phenomenological Ontology." Like Heidegger, whose presence is palpable in this work as was that of Husserl in the earlier ones, Sartre begins his study with the being for whom being is a problem, namely, *human reality* (Heidegger's *Dasein*). By accepting this translation of that basic Heideggerian term, Sartre already seems to be following the anthropological track that Heidegger sought to move beyond. But, in fact, Sartre, too, is concerned with gaining access to being in order to delineate its fundamental modes. Still, his point of access is the immediate experience of the *phenomenon of being* in experiences of boredom, nausea, and the like.

In his novel *Nausea*, Sartre's protagonist experiences the sheer contingency of the tree root that captures his attention, its gratuitous *existence*—and his own: "Every existing thing is born without reason, prolongs itself out of weakness and dies by chance" (*Nausea* 1964, p. 113). Sartre's formal ontology in *Being and Nothingness* will follow from the descriptive analysis of that phenomenon of the being of things. Against idealism, against those who succumb to the *illusion of immanence*, Sartre insists on the *transphenomenal* character of being, that is, its irreducibility to appearances. Showing himself as much the pupil of Henri Bergson as of Heidegger in this regard, Sartre appeals to a *revealing intuition of the phenomenon of being*. But this being is not some Kantian thing-in-itself standing behind the appearances; the phenomenon of being is coterminous with, though irreducible to, the being of the phenomena. The phenomena that the eidetic

reduction yields are the objects of knowledge; for example, the kind of knowledge that we gain about the nature of imaging consciousness. Such phenomena are reflective and our awareness of them cognitive. The phenomenon of being is prereflective and noncognitive. It follows that knowledge cannot give an account of transphenomenal being. To attempt to do so Sartre calls *metaphysics*, to which he gives short shrift toward the end of the book.

Using the phenomenological method of descriptive analysis, Sartre discovers three irreducible modes of being, namely, being in-itself, or the inert; being-for-itself, or the spontaneous (consciousness); and being-for-others, or the interpersonal. Though he claims that the for-others is as fundamental as the for-itself, it is clear that being-for-others is inconceivable without the other two, which are conceivable without it. So having distinguished between being and the phenomena, Sartre's descriptive analysis now reveals two radically different regions of being: the transphenomenal *being* of the prereflective cogito or *I think* that precedes and sustains any reflective awareness such as Descartes's *Cogito* or any other phenomena insofar as they are consciousness-relative, on the one hand, and the transphenomenal being of the objects of consciousness, revealed in the experiences of nausea, boredom and the like, on the other.

Pursuing this analysis, Sartre discovers that consciousness, which he will soon call *being-for-itself*, simply is the transphenomenal dimension of nonbeing, which he calls *nothingness* (*le néant*), the nothingness of *Being and Nothingness*, whereas *being-in-itself* denotes the dimension of transphenomenal being of the object of consciousness. Each region bears distinctive features. Being in-itself, in Sartre's metaphorical discourse, is thing-like in its solidity and identity. An inert plenum, the in-itself simply is what it is. This region includes any aspect of experience that manifests these properties; for example, substances or the temporal past or any of the *givens* of our experience that Sartre, borrowing from Heidegger, calls our *facticity*. Once other subjects enter the scene and a third, irreducible, dimension emerges, which Sartre calls *being-for-others* (*l'être-pour-autrui*), the scope of facticity expands to include such givens as our reputations, social institutions, and cultural phenomena generally. These, too, are forms of being-in-itself.

Being-for-itself bears contradictory features. As the nothingness of *Being and Nothingness*, the for-itself is the internal negation, or *nihilation*, of the in-itself. Sartre agrees with Heidegger that negativity is not simply a property of propositions but that it is introduced into the world by human reality itself. As evidence, Sartre cites a

whole series of *negativities* (*négativités*), such as our experience of the *fragility* of entities, of absence, of distance, of distraction, of regret, and of lack. (Recall his characterization of imaging consciousness). The for-itself is an exception to the Parmenidean rule of self-identity: Consciousness is nonself-identical. It is always *other* than itself, which is an ontological expression of its intentionality.

That *inner distance* that separates consciousness from itself accounts for three major characteristics of *human reality* (which is the human being as a composite but not a synthesis of these two ontological regions, related as thing and no-thing). First, it gives rise to the three dimensions of original, *ekstatic* temporality whereby human reality *stands out* from the other and from its very self, namely, the past as facticity, the future as existence or project, and the present as presence-to. This is another way of parsing the nonself-identity of the for-itself. A second consequence of this *gap* or *time lag* that consciousness introduces is the ontological freedom that characterizes our existence. Human reality is free, Sartre insists, because it is not a self but a presence-to-self. Part of Sartre's political endeavor after the war is to pursue the kind of *concrete freedom* that completes this abstract freedom as the definition of the human. Finally, it is this nonself-coincidence that accounts for the paradoxical discourse that Sartre adopts with regard to human reality. Besides the traditional paradoxes of temporality that he inherits, the chief paradox is that human reality *is what it is not* (its possibilities) and *is not what it is* (its facticity as *nihilated* by consciousness). On this account, whatever I am, be it my previous choices or the labels others have affixed to me, I am in the manner of *not-being* them, that is, with the possibility of changing my particular stance in their regard. For the quasi motto of Sartrean humanism is that *you can always make something out of what you've been made into*. This is both the burden of our responsibility and the source of our hope.

With the advent of another subject into my world comes another realm of being as well—being-for-others. Ontologically, this gives rise to an additional set of characteristics that belong to the interpersonal dimension of our existence. The existence of the other subject cannot be deduced; it must be encountered. The most dramatic argument for the existence of other subjects is Sartre's eidetic reduction of shame consciousness. His descriptive analysis centers on the experience one has of being caught in the act of looking at a couple through a keyhole. The feeling of shame that registers in bodily changes such as the face turning red is stronger evidence for the existence

of other minds, Sartre believes, than any argument from analogy. As he unpacks the experience, in one and the same moment, I become aware of the vulnerability of my embodiedness to the look of the other. In other words, what is revealed in this instant is my prereflective consciousness of being objectified by that gaze of another subject. My experience of objectification is simultaneously my experience of the other as subject. Even if on this occasion I happen to be mistaken about the source of the sound I hear behind me, the experience is indicative of being seen by another.

Though Sartre admits that other, derivative modes of access to being-for-others are available (for example, the existence of cultural objects such as directional signs or language itself), he insists that *the look* (*le regard*) is the basic form of interpersonal relation, and he interprets this gaze as objectifying and alienating. "Conflict is the original meaning of being-for-others" (Sartre 1943/1956, p. 364). The interpersonal is like a game of mutual stare-down, each trying to objectify the other. The only type of social philosophy that one can expect from such a thesis is a Hobbesian *war of all against all*. In a famous footnote Sartre concedes that "an ethic of deliverance and salvation" is possible but that this can be achieved only after "a radical conversion" which, he insists, cannot be discussed in that work (Sartre 1943/1956, p. 412). In fact, the elements of an ethic of authenticity are sketched in his posthumously published *Cahiers pour une morale* (Notebooks for an Ethics) composed in 1947–1948, where the basics of this *conversion* are discussed.

Human reality is being-in-situation. *Situation* is composed of facticity and freedom as transcendence; that is, the given that we are always surpassing in our projects. Though he insists that the situation is an ambiguous phenomenon because the precise contribution of each component cannot be determined, it is clear that, as Sartre's sense of social conditioning increases with his shift from abstract to concrete freedom, his respect for the force of circumstance in our situations grows apace. At this stage of his thought, he seems ambivalent as to the limiting and conditioning role of facticity in our actions. But later in life Sartre's sense of what Max Weber called *objective possibility* will heighten and, with it, the claim that fundamental changes in our socioeconomic system are required for abstract freedom to be made concrete. Thus, he will note shortly after the end of the war that "it is the elucidation of the new ideas of 'situation' and of 'being-in-the-world' that revolutionary behavior specifically calls for" ("Materialism and Revolution," Michelson 1962, p. 253).

It is in the context of situation that the concept of bad faith arises. Bad faith is a kind of self-deception, a sort of lying to oneself about the truth of one's situated being. Its most common form consists in collapsing our transcendence (our freedom) into our facticity by appeal to a type of determinism or by simply confessing: *That's just the way I am*. It is a denial of the possibility that consciousness brings to every situation. A related version of this type appeals to the image I wish to present to others or the one they have of me. That, too, is part of my facticity with which I seek to identify in self-deception as if my consciousness did not resist any attempt at full identity. A less common form of bad faith *volatilizes* our facticity into transcendence by choosing to ignore the givens of our situation. This is the bad faith of the dreamer or of the person who flees their past as if it were not part of their situation. But the possibility for self-deception arises from the *dividedness* of our consciousness as prereflective and reflective such that one can be prereflectively aware of more than one knows at the reflective level. Not that one is dealing with two consciousnesses: This deception occurs within the unity of one and the same consciousness.

Since Sartre denies the existence of the Freudian unconscious as he understands it because of its incompatibility with the ontological freedom of human reality, this notion of bad faith cannot appeal to unconscious drives or complexes. What Sartre calls *existential psychoanalysis* aims at dealing with such phenomena as bad faith and fundamental project without appealing to unconscious motives. Its basic premise is that "*man is a totality and not a collection*" (Sartre 1943/1956, p. 568). In other words, at the base of human reality is a fundamental, unifying *choice* that establishes the criteria for all subsequent selections.

We come on the scene having already made that choice, which Sartre believes is guided by the ruling value to consciously be self-identical, that is, to be in-itself-for-itself—an ontological impossibility. This is the meaning of Sartre's famous claim that humankind is a *futile passion*. But how each one lives out that self-defining choice is revealed in the subsequent choices that define a life. "There is not a taste, a mannerism, or a human act," Sartre insists, "which is not revealing" (Sartre 1943/1956, p. 568). The task of psychoanalysis is hermeneutical: to interpret the specific nature of that fundamental choice, that is, the way one acquiesces in or resists that futile passion, by deciphering the symbols of a person's life. What he calls the possibility of *conversion* is the constant threat of altering this basic choice, which haunts our lives. Echo-

ing Danish philosopher Søren Kierkegaard, Sartre calls this the anguish that accompanies the experience of our radical freedom. Admitting that this psychoanalysis has yet to find its Freud, and with a nod toward the work that will occupy a good part of his remaining years, Sartre finds the intimations of such psychoanalysis in certain *successful biographies*.

In many ways, one can read *Being and Nothingness* as an argument moving from the highly abstract (nihilating consciousness, being in-itself and for-itself) to increasingly concrete phenomena such as my *concrete relations with others*, and culminating in the hermeneutic of our particular actions in order to determine the fundamental choice that defines the unity of our lives. Existentialist psychoanalysis both brings this undertaking to a close and opens the door for its application in the several *biographies* that will occupy Sartre's attention over the following decades.

THE CRITIQUE OF DIALECTICAL REASON. It was during the war, Sartre insists, that he discovered the philosophical significance of social relations. *Being and Nothingness*, with its emphasis on the *looking/looked-at* model of interpersonal relations, was incapable of explaining the positive reciprocity, collective action, and unintended consequences that a social philosophy requires. In fact, *Being and Nothingness* describes the *we subject* as a "purely subjective *Erlebnis* (experience)" (Sartre 1943/1956, p. 420). Sartre breaks the barrier that confined *Being and Nothingness* to the psychological by introducing the concepts of dialectical praxis, the practice-inert and the mediating third. Together, they account for the dialectical enrichment of individual praxis by group praxis that bears properly social predicates such as rights/duties, power, and function while preserving the freedom and responsibility of the individual, which is a defining characteristic of existentialist thought.

Praxis supplants *consciousness* in the lexicon of the *Critique*. It denotes human activity in its sociohistorical context. Praxis is dialectical in the sense that it both negates and conserves aspects of its object in a totalizing action that advances toward a more comprehensive viewpoint. Thus, the negative reciprocity of two boxers in a match, in Sartre's example, when viewed dialectically, is realizing an enveloping social whole called *professional boxing*, which itself invites a still broader contextualization in various socioeconomic systems, such as racism, colonialism, and capitalism. In Sartre's view dialectical thinking is holistic; unlike analytical reason, it welcomes properly social phenomena as irreducible to purely atom-

istic, usually psychological, relations. While admitting the validity of analytical reason within its domain, at a certain level of abstraction, he notes, the class struggle can be seen as the conflict of rationalities.

Sartre reserves a threefold primacy for free organic praxis in his social ontology: ontological, epistemic, and moral. Ontologically, there are only individuals and real relations among them. Praxis is the constitutive dialectic of social phenomena, which are relational entities constituted by individual praxes. This is true even of group praxis, which is the synthetic enrichment of individual praxes in relation, mediated by each member as *third* to every other. Epistemically, the intelligibility of the group and of other social units is a function of the intelligibility of individual praxis, which is its foundation. Sociohistorical intelligibility is dialectical, and the dialectic is grounded in individual praxis. In other words, Sartre denies the existence of a collective consciousness or subject except insofar as it can be seen as a quality of individuals-in-relation.

Sartre speaks of *comprehension* as the *translucidity of individual praxis*. It assumes the clarity that Sartre has reserved for the prereflective cogito in *Being and Nothingness*. The moral primacy of individual praxis follows from the other two forms. Sartre is intent on preserving the moral responsibility of the group members as well as of those he describes as *serialized* by the mediation of worked matter, such as the television-viewing audience or the crowd waiting for a bus. In either case, whether *the same* in group activity and concern or *other* through the separation effected by the mediation of material things, individuals retain moral and not just causal responsibility for the praxis that sustains such relations.

The second basic component of Sartre's social ontology is what he calls the practico-inert. This complex term introduces aspects of being-in-itself into the realm of action. Sartre describes it as "simply the activity of others in so far as it is sustained and diverted by inorganic inertia" (Sartre 1960/1985, p. 556). Not raw nature, but the *practico-inert* is this mediating factor. It includes the sedimentation of prior praxes whether in the form of socioeconomic systems such as colonialism and capitalism or as alienating forms of thought and behavior such as racism, which Sartre calls a *serial idea*. It constitutes the material memory of a society.

Sartre allows for two fundamental kinds of social reality: the active group constituting the *common field* and the effectively separated though ostensibly united (*serialized*) individuals forming the *practico-inert field*. The practico-inert constitutes *fundamental sociality*.

Since Sartre conceives the group as arising through an essential negation of practico-inert seriality, he characterizes the practico-inert ensemble as *the matrix of groups and their grave*. This rich concept is amenable to analytic reason since it is atomistic in nature. But insofar as it occasions counterfinality in the sense that it sustains the boxer's feints and jabs, the conspirator's traps, and the unintended consequences of historical projects, its very antidialectic plays a role in dialectical rationality, conveying the experience of what Sartre calls *dialectical necessity*. Perhaps Sartre's best example of such counterfinality is the flooding and resultant soil erosion caused by Chinese peasants' deforestation undertaken to conserve their land.

But the concept of the mediating third is the key that opens the door to properly group praxis in Sartre's social ontology. There was a concept of the third in *Being and Nothingness*, but this third exercised an objectifying and an alienating function in accord with the looking/looked at model. That concept continues in the *Critique*, where it generates the alienating relations of serial individuals and collectives. But the *mediating* third is a functional concept denoting the group member who is *the same* as the others in common interest and action. As such, it does not objectify or diminish but enriches the responsibility of each in a common practice. Sartre refers to this ternary relation as a *free, interindividual reality*. Simply put, where the practico-inert mediates, human relations are serial; where praxis mediates, these relations are free. And where the practico-inert is modified by material scarcity, Sartre argues, this mediation becomes violent. Such is his bridge between social ontology and history as we know it.

AN EXISTENTIALIST BIOGRAPHER AND HISTORIAN

In *Search for a Method*, reprinted as a kind of preface to the *Critique* but more properly its sequel, Sartre introduces the progressive-regressive method for investigating social phenomena. This hybrid of existentialist psychoanalysis and historical materialism serves as the model for his later biographies, especially his multivolume study of Gustave Flaubert's life and times, *The Family Idiot*. Sartre studies the socioeconomic and cultural structures of Flaubert's life, particularly as these conditioned the choices available to a would-be literary artist in the second and third quarters of the nineteenth century (the *regressive* movement), the better to chart the spiral of Flaubert's *personalization* as artist, novelist, and finally author of *Madame Bovary* (1956) (the *progressive* stage). The approach is dialectical in its emphasis on the factors that *mediate* these abstract conditions toward their con-

cretization in Flaubert's *choice* of the imaginary, that is, of an artist's life. Indicative of Sartre's increasingly nuanced opposition to the Freudian unconscious is his remark that "everything took place in childhood ... a childhood we never wholly surpass" (Barnes 1968, p. 59–60 and 64).

The dialectic expands to include the *objective spirit* of the age, which Sartre characterizes as *culture as practico-inert*. Using an expression that Aron had employed to describe narrative history in general, Sartre calls *The Family Idiot a novel that is true (un roman vrai)*. Its dialectical interlacing of history and biography render it a properly existentialist approach to historical understanding.

A MORALIST

If Sartre was a philosopher of the imagination and an ontologist, he was above all a moralist in the French tradition of Duc François de La Rochefoucauld and François-Marie Arouet de Voltaire. His earlier philosophy of consciousness, as well as the primacy of praxis in the social ontology of the *Critique*, are conceived to preserve freedom and responsibility that are the hallmarks of vintage existentialist thought in the midst of impersonal forces, and what Louis Althusser (1918–1990) called *structural causality*. In the hyperbolic mode that he favored, Sartre insisted that *we are without excuse*.

In the course of his life, Sartre developed one ethical theory, sketched a second, and gestured toward a third, in that order. The first and best known is his ethic of authenticity. He describes *authenticity* briefly in *Réflexions sur la Question Juive (Anti-Semite and Jew)* (1946) as "having a true and lucid consciousness of the situation, in assuming the responsibilities and risks that it involves, in accepting it in pride or humiliation, sometimes in horror and hate" (Becker 1995, p. 90). This seems to yield an ethical style rather than a content. It stresses doing rather than being in the sense of embracing my ontological condition, namely, that whatever I am, I am in the manner of not-being it, that is, in nihilating it. I am its *creative unveiling*, with the anguish and joy that accompanies that prereflective awareness.

The ethical content emerges in his novels, stories, plays, and biographies, especially his biography of Jean Genet, *Saint Genet: Comédien et martyr* (Saint Genet, actor and martyr) (1952) and is elaborated in his posthumously published *Notebooks for an Ethics*, which discusses such concepts as good faith, generosity, and positive reciprocity. Maximizing concrete freedom of choice and action becomes an increasingly important moral precept

as Sartre's social sense confronts exploitative systems and oppressive practices after the war.

Exchanging the vocabulary of *Being and Nothingness* for the discourse of the *Critique* in the notes for two sets of lectures and a collection of unpublished reflections from the same period, Sartre sketches a second, *dialectical* ethics that promotes the value of *integral humanity*. This value includes the moral imperative to satisfy human needs by harnessing the practico-inert. Elsewhere, Sartre envisions a socialism of abundance and the new, currently inconceivable, philosophy of freedom that will follow upon it. These lecture notes seem to turn this ideal into an obligation based on the nonnegotiability of basic human needs. In his last discussions with Lévy, he speaks of an ethic of the *we* that will revise many of his previous claims in this regard. However, these recorded remarks were published only in part, and what is available thus far, despite suggestive insights, does not constitute a coherent moral theory. They remain chiefly of biographical interest.

CONCLUDING OBSERVATIONS

One of the strengths of Sartre's philosophical thought is its insight into the psychological and moral life of individuals and societies. That same gift for imaginative interpretation that fits so well with descriptive phenomenology and makes him a prize-winning novelist and playwright is suspect in the court of conceptual analysis. And once Sartre turns to historical dialectic, the suspicion is compounded. Much of this is simply philosophical bias, which Sartre attempted to address with his distinction between dialectical and analytical reason and their respective logics. But some of it is a reasonable distrust of a lack of rigor evidenced by what Iris Murdoch called Sartre's *great inexact equations*. And then there are his rather extreme political positions and their accompanying moral ascriptions. While one cannot help but admire Sartre's outrage at social injustice and hypocrisy, a remark once reportedly made about Bertrand Russell could be extended to Sartre in this regard: He has the uncanny ability to hit the bull's-eye on the first shot but undermined by a tendency then to splatter all over the target in exaggeration.

Still, Sartre's observations on bad faith and authenticity are now staples in the ethical discourse of our day. And the basic concepts of his social ontology, namely, praxis, the practico-inert, and the mediating third, make a significant contribution that merits the close scrutiny that the prolixity of the *Critique* has denied them. The Cartesian dualism often attributed to Sartre is misap-

plied. His is not a two-substance ontology since only the in-itself is substantial. But a survey of his social ontology in the *Critique* suggests that his dualism is best described as one of spontaneity and inertia, which sends us back to imaging consciousness once more. Perhaps nowhere is the relation between philosophy and imaginative literature more acutely problematized than in Sartre's work. That, too, deserves close attention. Finally, the lessons of Sartrean existentialism speak directly to the renewed interest among our contemporaries in philosophy as a way of life.

Bibliography

For a complete annotated bibliography of Sartre's works, see *The Writings of Jean-Paul Sartre*, edited by M. Contat and M. Rybalka. Evanston, IL: 1973, updated in *Magazine littéraire* 103–104 (1975): 9–49, and by Michel Sicard in *Obliques* 18–19 (1979): 331–347. Rybalka and Contat have compiled an additional bibliography of primary and secondary source published since Sartre's death in *Sartre: Bibliographie, 1980–1992*. Paris: CNRS éditions, 1993.

Bulletin du Groupe d'Études Sarrtriennes, the *Yearbook of Sartre Studies*, has published annually since 1987 a list of recently published works of Sartre as well as secondary source material in several languages. Information about this publication, its bibliographies, and the work of the *Groupe* can be found at www.jpsartre.org.

WORKS

L'imagination. Paris: Félix Alcan, 1936. Translated by Forrest Williams as *Imagination, A Psychological Critique*. Ann Arbor: University of Michigan Press, 1962.

“La transcendance de l'ego. Esquisse d'une description phénoménologique.” In *Recherches philosophiques* 6 (1936): 65–123. Reprinted in edition by Sylvie le Bon, Paris, 1965. Translated by Forrest Williams and Robert Kirkpatrick as *Transcendence of the Ego: An Existentialist Theory of Consciousness*. New York: Octagon Books, 1972.

La nausée. Paris: Gallimard, 1938. Translated by Lloyd Alexander as *Nausea*. New York: New Directions, 1964.

Esquisse d'une théorie des émotions. Paris: Hermann, 1939. New edition, 1960. Translated by Bernard Frechtman as *The Emotions. Outline of a Theory*. New York: Philosophical Library, 1948.

L'imaginaire. Paris: Gallimard, 1940. Translated by Jonathan Webber as *The Imaginary: A Phenomenological Psychology of the Imagination*. London: Routledge, 2003.

L'être et le néant. Paris: Gallimard, 1943. Translated by Hazel E. Barnes as *Being and Nothingness; An Essay on Phenomenological Ontology*. New York: Philosophical Library, 1956.

Réflexions sur la question Juive. Paris: P. Morihien, 1946. Translated by George J. Becker as *Anti-Semite and Jew*. New York: Schocken, 1995.

L'existentialisme est un humanisme. Paris: Gallimard, 1946. Présentation et notes par Arlette Elkaïm-Sartre. Paris: Gallimard, 1996. Translated by Philip Mairet as *Existentialism and Humanism*. London: Meuthen, 1957. Also translated by Bernard Frechtman as *Existentialism*. Secaucus, NJ: Citadel 1957.

Situations. 10 vols. Paris: Gallimard, 1947–1976. Contains reprints of important essays and interviews such as “La Liberté Cartésienne” (Vol. 1, pp. 289–307) and “Matérialisme let Révolution” (Vol. 3, pp. 135–223). Translated by Annette Michelson as “Cartesian Freedom” and “Materialism and Revolution.” In *Literary and Philosophical Essays*. New York: Collier, 1962.

Qu'est-ce que la littérature? Les temps modernes 17–22 (1947): no. 17, pp. 769–805; no. 18, pp. 961–88; no. 19, pp. 1194–1218; no. 20, pp. 1410–1429; no. 21, pp. 1607–1641; no. 22, pp. 77–114. Reprinted in *Situations* 2. Paris: Gallimard, 1948. pp. 55–330. Translated by Bernard Frechtman et al. as *What Is Literature? And Other Essays*. Cambridge, MA: Cambridge University Press, 1988.

Saint Genet: Comédien et martyr. Paris: Gallimard, 1952. Translated by Bernard Frechtman as *Saint Genet: Actor and Martyr*. New York: G. Braziller, 1963.

Critique de la raison dialectique, précédé de questions de méthode. Vol. 1, *Théorie des ensembles pratiques*. Paris: Gallimard, 1960. Reprinted in a new annotated edition, 1985. The prefatory essay to the *Critique*, “Questions de méthode,” appeared in *Les temps modernes* 139–140 (1957): no. 139, pp. 338–417; no. 140, pp. 658–698. Translated by Hazel E. Barnes as *Search for a Method*. New York: Random House, 1968. An annotated edition of *Questions de méthode* by Arlette Elkaïm-Sartre appeared in 1986. Paris: Gallimard, collection Tel. The *Critique* itself was translated by Alan Sheridan-Smith as *Between Existentialism and Marxism (Essays and Interviews, 1959–70)*. Translated by John Mathews. London: NLB, 1974.

Les mots. Paris: Gallimard, 1964. Translated by Bernard Frechtman as *The Words*. New York: G. Braziller, 1964.

L'idiote de la famille; Gustave Flaubert de 1821–1857. Vols. 1–3, Paris: Gallimard, 1971–1972. Revised edition of Vol. 3, 1988. Translated by Carol Cosman as *The Family Idiot: Gustave Flaubert, 1821–1857*. 5 vols. Chicago: University of Chicago Press, 1981–1993.

On a raison de se révolter: Discussions. With Philippe Gavi and PierreVictor. Paris: Gallimard, 1974.

Critique of Dialectical Reason. Vol. 1, *Theory of Practical Ensembles*. London: NLB, 1976. A new edition based on the revised French edition of 1985 appeared in 2004. London: Verso.

SAVAGE, LEONARD

(1917–1971)

Leonard James Savage was the most influential Bayesian statistician of the second half of the twentieth century. Born November 20, 1917, in Detroit, Michigan, Savage received his PhD in mathematics at the University of Michigan in 1941. He then spent a year serving as John von Neumann's assistant at the Institute for Advanced Study in Princeton, where he was exposed to von Neumann's ideas on game theory and the mathematical modeling of human behavior, topics that became a central focus of Savage's research. In his next position at Columbia University's wartime Statistical Research Group—whose members included such luminaries as Abraham

Wald, Milton Friedman, Harold Hotelling, Fredrick Mostler, and Abraham Girshick—Savage developed an interest in statistics and became convinced that the subject should be grounded on a “personalist” conception of probability. After Columbia, Savage went on to hold academic positions at Chicago, Michigan, and Yale.

Savage’s research focused on the mathematical analysis of rational belief and desire, and the advancement of Bayesianism in statistics. His masterpiece, *The Foundations of Statistics* (1954), pursued both these projects by first developing what has come to be the canonical version of subjective expected utility theory, and then attempting to recast all of statistical methodology along subjectivist Bayesian lines.

SAVAGE’S CONTRIBUTIONS TO DECISION THEORY

Savage’s most notable contributions to the study of rational behavior were his construction of a general framework for modeling decisions under uncertainty, his systematic defense of subjective expected utility maximization as the hallmark of rational choice, and his innovative account of the role of “personal” probabilities in decision making.

Savage portrays decision making as being a matter of using beliefs about possible *states of the world* to choose *actions* that provide the optimal means of producing desirable *consequences*. Actions are identified with functions from states to consequences, and the agent is assumed to have a preference ranking over all acts at her disposal. Influenced by the behaviorism that dominated the social sciences of his day, Savage interpreted preferences operationally, so that an agent may be said to prefer one act *f* to another *g* if and only if she would be disposed to freely choose *f* over *g*. Overt choices thus function as “observables” in decision theory, and talk about the underlying beliefs and desires that cause them is rendered scientifically respectable by showing how they can be operationally defined in terms of preferences. (Savage’s behaviorism remains controversial, but some commentators, e.g., Joyce (1999), regard it as inessential to his overall account of rationality.)

Following Frank Ramsey (1931) and Bruno de Finetti (1937), Savage invoked the hypothesis of subjective expected utility maximization to forge a link between empirically measurable preferences and hidden beliefs and desires. Given a probability function *P* defined over states of the world, and a utility function *u* defined over consequences, the expected utility of an act *f* is the probability-weighted average of the utilities of *f*’s conse-

quences. When there are finitely many states, s_1, s_2, \dots, s_n , this expected utility is defined as $Exp_{P,u}(f) = P(s_1)u(f(s_1)) + P(s_2)u(f(s_2)) + \dots + P(s_n)u(f(s_n))$. Savage maintained that an agent’s preferences can only be deemed rational to the extent that they can be represented as ranking acts according to increasing subjective expected utility.

To establish this conclusion, Savage proposed that any rational preference ranking should satisfy a specific system of axiomatic constraints. The central axiom is the *sure-thing principle*, which states, roughly, that for any acts *f* and *g*, and any event *E*, if *f* is preferred to *g* both conditional on *E* and conditional on not-*E* then *f* is preferred to *g* outright. Savage went on to prove that any preference ranking satisfying his axioms implicitly defines a unique subjective probability *P*, which represents the agent’s degrees of confidence in various states, and a utility *u*, which gauges the strength of her desires for consequences. The agent prefers *f* to *g* just in case $Exp_{P,u}(f) > Exp_{P,u}(g)$. In this way, the hypothesis of expected utility maximization allows us to extract degrees of belief and desire from rational preferences.

Many objections to Savage’s theory misinterpret it as a descriptive account, but it was clearly meant to be prescriptive. The most serious doubts about the theory’s normative import concern the status of the sure-thing principle, which some critics see as improperly prohibiting certain sorts of rational aversions to risk or uncertainty. Savage always regarded such worries as misguided, and steadfastly defended the principle’s normative credentials. Many people agree with him, as evidenced by the fact that Savage’s theory, or its close variants, remain central to treatments of rational decision making across the social sciences.

SAVAGE’S CONTRIBUTIONS TO STATISTICS

Savage maintained that the subjective or “personal” probabilities that figure into decision making should serve also as the basis for statistical reasoning. He implacably opposed the frequentist paradigm that had come to dominate statistics during the 1930s and 1940s. In *Foundations* Savage had tried to incorporate the methods of frequentist statisticians, like Ronald A. Fisher and Jerzy Neyman, into his personalist framework, but by the end of his career he had entirely “lost faith in the devices of the frequentist schools” (Savage 1954). In the second edition of *Foundations* (1972), written six months before his death, he rejects as “ill-founded” such frequentist devices as minimax rules, confidence intervals, tolerance intervals, significance tests, and fiducial probabilities. To take

their place he advocated a thoroughgoing Bayesianism in which all question of statistical reasoning boil down to the choice of a prior personal probability and the use of Bayes's rule to alter personal probabilities in light of evidence.

Savage made many contributions to the development of Bayesian statistics, of which the most significant are these: He proved a "washing-out" theorem that shows how, under fairly unrestrictive conditions, Bayesian agents with diverse prior probabilities will eventually converge to the same posterior given a sufficiently long run of shared observations. In a highly influential paper, written with Ward Edwards and Harold Lindeman (1963), he established the principle of stable estimation, which specifies conditions under which the value of a posterior probability will be independent of its prior. In one of his last papers, he developed an elegant general method for eliciting personal probabilities using proper scoring rules (1971). Savage died November 1, 1971, in New Haven, Connecticut, after having made lasting and seminal contributions to statistics, decision theory, psychology, and economics.

SAVIGNY, FRIEDRICH KARL VON

(1779–1861)

Friedrich Karl von Savigny, the founder of historical jurisprudence, was born in Frankfurt, Germany, into a family that had moved there from Lorraine. Left an orphan at thirteen, Savigny was brought up by a friend who educated him in ways that recall the experience of young John Stuart Mill. At seventeen Savigny entered the University of Marburg; after studying at other universities, he returned to Marburg for his doctor's degree in 1800 and began a long, influential, and distinguished teaching career. At the age of twenty-four he published *Das Recht des Besitzes* (The Right of Possession; Giessen, 1804), and in the following year he began to tour libraries in search of manuscripts for his historical work. In 1810 he accepted a teaching post at the newly founded University of Berlin, which he helped organize and where he became rector. He did much to raise the standards of German universities and to help them achieve a dominant position in the world of scholarship. While teaching, writing, and assisting in the administration of the university until 1842, he also performed judicial tasks, and from 1842 to 1848 he was chancellor of Prussia.

In his stress on continuity and tradition Savigny may have been influenced by Edmund Burke, and in his understanding of the methods and aims of historical research he may have been influenced by Barthold Georg Niebuhr, who also took part in the founding of the University of Berlin and was an admirer of Roman institutions.

Savigny's two *magna opera* were the *Geschichte des römischen Rechts in Mittelalter* (7 vols., Heidelberg, 1815–1834) and the *System des heutigen römischen Rechts* (8 vols., Berlin, 1840–1849). In 1850 his miscellaneous writings, *Vermischte Schriften*, were published at Berlin in five volumes, and in 1851 and 1853 his two-volume work *Das Obligationenrecht als heute römischen Rechts* was published. He was cofounder, in 1815, of the *Zeitschrift für geschichtlichen Rechtswissenschaft*. His massive work on Roman law in the Middle Ages became the source of subjects for countless historical monographs. His students, and their students in turn, dominated historical and legal scholarship and teaching for several generations, and he was universally acknowledged as one of the most influential thinkers and scholars of the nineteenth century.

The main thrust of Savigny's jurisprudential thought, however, is not found in his monumental his-

torical treatises but in a polemical tract published at Tübingen in 1814, *Vom Beruf unserer Zeit für Gesetzgebung und Rechtswissenschaft*. This pamphlet was in rebuttal to A. F. J. Thibaut's *Civilistische Abhandlungen* (Heidelberg, 1814), in which a plan for a single code of laws for all German states was urged.

Savigny argued that law has no abstract origin in nature or mind but is organically connected with the people of a nation and is an expression of its *Volksgeist*, or collective genius. Fundamentally, law is formed by custom and popular faith, "by internal, silently operating powers, not by the arbitrary will of a lawgiver." The "real law" is always "the proper will of the people." Like language and manners, law has movement and development; it grows with a people and dies with it.

In earliest historical times, Savigny claimed, law was no more separable from a people than was its language or its manners. Rights and duties were created and extinguished by symbolic acts, which were the "true grammar" of law in this period. As social existence became more complex and sophisticated, law came to be expressed in abstract forms; jurists became a professional class, and law perfected its language and took a scientific direction. Instead of existing in the consciousness of the people, it now existed in the consciousness of the jurists, who became the representatives of the community, the voice of its *Volksgeist*. Now the law had a twofold existence: the "political" element, or the connection of the law with the general existence of the people, and the "technical" element, or the abstract and scientific existence of the law. From this it follows that the jurist needs a twofold spirit: the historical sense, with which to seize "the peculiarities of every age and every form of law," and the systematic sense, with which to see "every notion and every rule in lively connection and cooperation with the whole" legal order. Through these senses the jurist will acquire mastery over a body of law, obtain for that law a thorough grounding in history, and discover its organic principle. He will be able to separate that which still has life from that which is lifeless "and only belongs to history," and in this way he will arrive at a truly national law—a "living customary law."

Savigny's views contributed in varying degrees to a number of significant results: (1) They helped bring to an end the dominant natural law philosophy that looked to pure reason as the source of law. (2) They delayed the movement for codified legal systems that had started with the Napoleonic codes. (3) They established the historical school of jurisprudence. (4) They laid the basis for the sociological school of legal thought. (5) They retarded the

development and acceptance of legislation as a source of law. (6) They contributed to an exaggerated stress on nationalism and to a disparagement of the idea of a common law of humankind as an expression of *Menschengeist*. Perhaps Savigny's most enduring influence is to be found in his idea that law must not be isolated into an autonomous science but must be treated as an aspect of social life, development, and order—as a social, historically conditioned phenomenon.

SCHELER, MAX

(1874–1928)

A pioneering German phenomenologist, ethicist, and social philosopher, Max Scheler was born in Munich in 1874. His father was Lutheran, his mother was Jewish; Scheler himself, ever independent, embraced Catholicism. After studying with Wilhelm Dilthey and Georg Simmel, he earned his doctorate in 1897 under Rudolf Eucken in Jena, where he taught until 1906. From 1907 he taught in Munich, where he met Franz Brentano and sev-

eral disciples of Edmund Husserl, the father of the phenomenological movement. He soon became acquainted with a growing circle of phenomenologists from Munich and Göttingen, including Moritz Geiger (1880–1937), Dietrich von Hildebrand (1889–1977), Alexander Pfänder, Adolf Reinach (1883–1917), Edith Stein, and others. But as early as 1901, when he first met Husserl, Scheler had already taken an independent phenomenological direction of his own.

In 1910 Scheler lost his post in Munich after a divorce alienated him from the Catholic university administration. In 1912, he married Märit Furtwängler, sister of the noted conductor. From 1910 to 1919, he freelanced as an independent scholar, publishing a prolific number of works, particularly on ethics, but also on political issues of the day, including war, capitalism, feminism, the psychology of resentment, and various social issues. He served on diplomatic missions to Switzerland and the Netherlands. After World War I, he actively promoted the causes of international reconciliation, moral renewal, pacifism, and European reunification based on ideals of Christian socialism. It was not until 1919 that Scheler received a full professorship, in Cologne, where his focus turned to religion, anthropology, metaphysics, and sociology of knowledge. By 1922 he had fallen away from Catholicism in favor of a pantheistic conception of divine self-realization in history. He died on the eve of assuming his final post in Frankfurt in 1928, after repeatedly warning against the rise of German Nazism and Italian Fascism. His writings were suppressed by the Nazis in Germany from 1933 to 1945.

Scheler's impact on the phenomenological movement was considerable, despite ambivalent relationships with Husserl and Martin Heidegger. Many prominent thinkers have acknowledged their debt to him, including Jean-Paul Sartre, Maurice Merleau-Ponty, Gabriel Marcel, Nicolai Hartmann, Roman Ingarden, Hans-Georg Gadamer, Martin Buber, and José Ortega y Gasset. Pope John Paul II wrote a doctoral dissertation on him. Scholars in the Spanish-speaking world, Japan, and Russia were well acquainted with Scheler long before he was known in the English-speaking world.

Scheler's most important phenomenological works were published during his prolific middle period. These include *Formalism in Ethics and Non-Formal Ethics of Values* (1913–1916), his seminal critique of Immanuel Kant's ethics and outline of his own phenomenological ethics based on a theory of values. His 1916 essay *Ordo Amoris* develops his Pascalian conception of a faculty of cognitive feeling independent of reason, which apprehends a hier-

archical array of values in its pure incontrovertible immediacy. Between 1912 and 1913 he also published phenomenological studies of sympathy, love, and hate in *The Nature of Sympathy*, and a study of resentment and impotence in modern bourgeois morality in *Ressentiment* (1994 [1964])—a brilliant transmutation of Friedrich Nietzsche's claim that Judeo-Christian morality stems from resentment, eliciting Ernst Troeltsch's famous characterization of Scheler as “the Catholic Nietzsche.”

While initially collaborating with Husserl, Scheler criticized Husserl's “Cartesianism” and for giving inordinate primacy to reason. By contrast, Scheler insisted on the primacy of feeling and its independence from reason in apprehending values, which he considered the primordial phenomena of consciousness. Scheler did not use Husserl's terms *noesis* and *noema* to distinguish the act of thinking from the object of thought, yet he recognized that this polarity within consciousness, first investigated by Brentano, allows for two approaches in investigation. Thus he distinguished *act-phenomenology* from *phenomenology of facts*, the former focusing on persons as the source of the unifying intention animating acts, the latter analyzing three types of facts—natural, scientific, and phenomenological.

The preeminent phenomenological facts overlooked by Kant, according to Scheler, are values. Kant rightly denies that moral obligation can be defined by reference to empirical objects of desire without subordinating it to the relativizing contingencies of particular whims, ends, and purposes. But he fails to discern the distinctive nature of values as pure qualities or essences, distinct from empirical entities or objects of desire that might serve as their bearers. Just as colors can be conceived independently of any colored surfaces or bearers, values can be intuited as pure, independent essences. Furthermore, values exhibit an objective hierarchical ranking, furnishing a material basis for ethics, in contrast to Kant's empty formalism. Accordingly, Scheler distinguishes four basic ranks of values. From highest to lowest, these include the (1) *religious*, such as the sacred and profane; (2) *cultural*, such as the true, right, and beautiful; (3) *vital*, such as the noble and common; and (4) *sensory*, such as the pleasant and painful. Scheler's criteria for this classification are reminiscent of Jeremy Bentham's hedonic calculus, including relative duration, depth of satisfaction, and so forth. He also held that this ranking reflects an a priori “logic of preference.”

As in teleological theories generally, Scheler defines moral values in terms of the nonmoral value realized or intended through an act. Accordingly, moral good is

achieved as a by-product of realizing or intending a positive or comparatively higher nonmoral value, such as sacrificing the lower value of physical comfort for the higher value of one's children's education. His ethic, unlike Kant's, is based not on "blind duty," but on positive insight into the nature of values.

Scheler is unabashedly objectivist and absolutist in his value theory, but acknowledges the relativity of actual value judgments among societies and individuals. Someone suffering a pathological urge to sacrifice does not have the same obligation to be selfless as the self-centered egoist. Differences of cultural ethos are also significant. Recognition of such relativities inform Scheler's theories of virtue, conscience, and obligation, as well as his concepts of types of *exemplary acts* and *exemplary persons*—such as saints, geniuses, and heroes—that he proposes as vehicles for moral education. Yet he steadfastly maintains that such relativities do not undermine the absolute objectivity of values themselves.

SCHELLING, FRIEDRICH WILHELM JOSEPH VON (1775–1854)

Friedrich Wilhelm Joseph von Schelling, the German idealist philosopher, was born at Leonberg in Württemberg, the son of a learned Lutheran pastor, Joseph Friedrich Schelling. From his earliest years, he was destined by his family for the ministry. He was educated at the cloister school of Bebenhausen and, from 1790 to 1792, at the theological seminary at Tübingen. There he became friendly with two older students who were to play significant roles in his own life, as well as in cultural history: G. W. F. Hegel and J. C. F. Hölderlin, the great romantic poet. The three young men were keen partisans of the French Revolution, and they also enthusiastically discussed the ideas of the philosophers, especially Benedict de Spinoza, Immanuel Kant, and Johann Gottlieb Fichte.

For several years Schelling held a position as tutor of the sons of a noble family. Then, in 1798, at the unusually young age of twenty-three, he was called to a professorship at Jena. There the famous Fichte, the leading philosopher in Germany at the time and the idol of Schelling's youth, became his colleague and friend. In 1802 and 1803 Schelling and Hegel jointly edited the *Kritisches Journal der Philosophie*. At that time, though Hegel was five years older than Schelling, he was generally considered to be Schelling's disciple, and Hegel's first book was a comparison of Fichte's and Schelling's philosophies.

In nearby Weimar, Johann Wolfgang von Goethe and Friedrich Schiller were at the peak of their careers. Schelling met them both and became friendly with Goethe. Jena was now the center of German romanticism, and the ideas and personalities of this movement made a profound and lasting impression on Schelling. The romantic movement was, of course, also influenced by his philosophy. In its stress on the importance of the individual and the supreme value of art, and in its antirationalism, organicism, and vitalism, Schelling's transcendental idealism is the epitome of German romantic philosophies.

His friends among the romantics included Ludwig Tieck, who interested Schelling in folklore and mythology; the brilliant young poet Novalis; and August and Friedrich von Schlegel, whose translations of William Shakespeare made the English playwright one of the main shaping forces of German literature. Schelling was particularly intimate with August and his charming, intellectually gifted wife Caroline. Soon he became infor-

mally engaged to Auguste Böhmer, the sixteen-year-old daughter of Caroline by a previous marriage, but she died in 1800 before they could marry. It was rumored at the time that Schelling's amateur medical attentions contributed to her death. Certainly he was impetuous and self-confident to a point that some felt bordered on irresponsibility. This was a personal pattern common among the romantics, who sometimes defended themselves with the words of Schelling, "The beginning and end of all philosophy is—freedom."

In 1803 Caroline divorced August Schlegel and married Schelling. In keeping with the romantic creed, the three remained friends. It seems to have been an ideal marriage in every way. Schelling produced his most successful works during these years, and when Caroline died in 1809 he was grief-stricken; from then on he seemed unable to put his ideas together in a way that satisfied him. He never published another book as long as he lived, though he continued to write and lecture for many years. In 1812 he married Pauline Gotter, a friend of Caroline's.

From 1803 to 1806 Schelling taught philosophy at the new University of Würzburg, and in 1806 he was called to Munich as an associate of the Academy of Sciences and as secretary of the Academy of Arts. He later became secretary of the philosophical section of the Academy of Sciences. These positions were government sinecures that afforded him abundant leisure and also allowed him to lecture at Stuttgart and, from 1820 to 1827, at Erlangen. In 1827 he became a professor at Munich. In 1841 the Prussian authorities, in the hope that he would serve as a counterbalance to the powerful influence of the radical Young Hegelians, appointed him to the position of Prussian privy councilor and member of the Berlin Academy, and he lectured for the next five years at the University of Berlin. He died at the age of seventy-nine at Bad Ragaz, Switzerland.

Of all the major German philosophers, Schelling is the least known in the English-speaking world. His name is familiar as the historic link connecting Kant and Fichte with Hegel, but this description fits only his earlier work. Through his personal association with some of the German romantic writers and his doctrinal influence on the entire German romantic school, as well as through the direct influence of his aesthetics on Samuel Taylor Coleridge and, through Coleridge, his indirect influence on other English poets of the period, he is also known as the philosopher of romanticism. In his last phase, which was partly a conscious reaction to Hegel, he anticipated some of the central ideas of the existentialists, and for this

reason there has been a revival of interest in his later writings.

The development of Schelling's philosophy can be conveniently divided into four stages—subjective idealism, the philosophy of nature, the philosophy of identity, and the philosophy of the opposition of the negative and the positive. The stages are logically connected with one another, but also are clearly separate, so much so that their author was often accused of inconsistency. For example, Hegel wrote, "Schelling carried on his philosophic education before the public and signaled each fresh stage of his advance with a new treatise."

SUBJECTIVE IDEALISM

In the first stage Schelling was gradually working himself free from Fichte's subjective idealism to an independent position of his own. The major works of this phase were *Vom Ich als Prinzip der Philosophie, oder über das Unbedingte im menschlichen Wissen* (Tübingen, 1795), in which he posited the ego as the supreme, unconditioned element in human knowledge, and *Philosophische Briefe über Dogmatismus und Kritizismus* (in *Philosophisches Journal*, 1796), in which he compared Spinoza and Fichte. There is little that is original in these works other than the style and the tone. However, Schelling's style is important because its eloquence, its sense of emotional urgency, and its relative freedom from technical jargon—a rare trait in the writings of German idealists—all point to his affinity with the romantic movement and his unique philosophic stress on the importance of aesthetics.

PHILOSOPHY OF NATURE

The second stage, the philosophy of nature, was the most famous and the most influential of Schelling's philosophies and remained so until recent years. The first important work of this stage was *Ideen zu einer Philosophie der Natur* (Leipzig, 1797). Against Fichte's conception of the world as the construction of the ego, Schelling now insisted that the world of nature is just as real and just as important as the world of the ego. In fact, it is nature, the objective, that gives to consciousness what consciousness reproduces anew. Originally, consciousness and nature are one and infinite; but consciousness limits itself and presents itself to itself as finite, as different from nature. The essence of the ego is spirit, and the essence of nature is matter, but the essence of matter is force; that is, attraction and repulsion. In force, Schelling finds the common ground of nature and ego. As attraction it is objective, it is nature, it is matter; as repulsion it is subjective, it is ego, it is spirit. This duality also governs human perception:

As attraction to the self, force governs the streaming of the outer world into the inner world of sensation, and this internal experience of movement constitutes the a priori basis of time; as repulsion, pushing out into the world, force constitutes the a priori basis of space.

PHYSICAL SCIENCES. In *Von der Weltseele* (Hamburg, 1798) Schelling dealt with the philosophic problems of the physical sciences. He believed that the fundamental aim of the sciences was the interpretation of nature as a unity, and therefore the proper study of all sciences was force. He tried to show that mechanical, chemical, electrical, and vital forces were all different manifestations of the same underlying force. In the following year, in *Erster Entwurf eines Systems der Naturphilosophie* (Jena and Leipzig, 1799) and in *Einleitung zu dem Entwurf eines Systems der Naturphilosophie oder über den Begriff der spekulativen Physik* (Jena and Leipzig, 1799), he depicted this force as “pure activity.” He saw nature as an infinite self-activity, realizing itself in finite matter but forever unexhausted, forever short of completely realizing itself. He felt that he had thus found a parallel in the physical universe for Kant’s idea of the moral universe as practical reason forever striving toward an unattainable ideal. He further developed this phase of his thought in “Allgemeine Deduktion des dynamischen Prozesses” (in *Zeitschrift für spekulative Physik*, Vol. 1, 1800); *Über den wahren Begriff der Naturphilosophie; Darstellung meines Systems der Philosophie* (Jena and Leipzig, 1801); and *Bruno, oder über das göttliche und natürliche Prinzip der Dinge* (Berlin, 1802).

KNOWLEDGE. In the *System des transzendentalen Idealismus* (Tübingen, 1800), his most systematic and mature statement, Schelling applied to the philosophy of nature the insights gained from the Kantian and Fichtean philosophy of knowledge. His technique for deriving the world of objects from the world of the ego was to turn consciousness upon itself as the only object of which we have immediate firsthand knowledge. Thus, he found that when we abstract from all objects of knowledge, both within ourselves and in the outside world, we arrive at the pure activity of abstracting, which is pure self-activity. Seen in this light, the consciousness of the not-self is the limit of self-activity, just as the things-in-themselves are at the limits of knowledge in *The Critique of Pure Reason*.

On this foundation, Schelling built a theory of three stages of knowledge, which he described as progressing from sensation to perception, from perception to reflection, and from reflection to will. At first, consciousness of a limit, of the not-self, is felt as a sensation. The limit,

where the sensation is felt, is the meeting place of self-consciousness pushing outward and the force of the consciousness of external objects streaming inward. Therefore, all sensation is a feeling of myself as limited. Here we become aware of gravity, of the force of the real objective world in space, and also of intensity, which is the immediate consciousness of the self and its own activity in time. From the perception of the outside world comes reflection, and from reflection on the internal world comes will.

In this way Schelling felt that he had established links among Kant’s categories, schemata, and objects of perception. Aside from the technical question of the correctness of this linkage—certainly Kant would have disputed it—it has great historical importance, because this is perhaps the only area in which Schelling decisively influenced the fully matured philosophy of Hegel, who used this reasoning to connect the dialectic of thesis-antithesis-synthesis with Kant’s triadic formulation, though the dialectic itself was borrowed by Hegel from Fichte.

Schelling argued that the separation of knowledge from its object occurs only in abstraction. In reality, concepts have no existence apart from their objects, since knowledge is the meeting of objects and self. Therefore, the self is not merely one of the objects of knowledge; it is the condition of all knowledge. And since the essence of the self is pure self-activity, knowledge ultimately derives from willing, which is the action of the self.

OTHER MINDS. Schelling now asks two fundamental questions. How do I know there are other intelligences? And how can they act on me? He answers that our consciousness of limitations implies the existence of other selves that act as limiting factors. (Here he takes issue with Kant’s teaching that intelligence is limited by something not itself.) But the other selves can act on me only indirectly, through my representation of their acts. Their action does not compel mine, but limits it; and such limitation is compatible with my freedom. It is the community of interacting intelligences that constitutes the historical life of man. And while nature exists when not perceived by me, it exists then only because it is perceived by other human beings. Objectivity is intersubjectivity.

WILL AND IMAGINATION. Although perception is necessary and limited, will is free and unlimited. The imagination and its ideas mediate between perception and will. As opposed to the conceptions of the understanding, which are finite, the ideas of the imagination are both

finite and infinite. An idea's relation to its object is finite, but the activity of the imagination in this relation is infinite. Each idea is subsumed under an ideal, as conceptions are subsumed under their schemata in Kant. The function of the will is to idealize the imagination's ideas. The contradiction thus engendered gives rise to impulse, defined as the desire to restore destroyed identity. Through impulse, there is constant realization of ideals, but the ideas of the imagination are constantly striven after and never attained.

WILL AND KNOWLEDGE. The distinction between will and intelligence thus is relative, not absolute. From a higher point of view, they are identical. In intelligence, the I that acts and the I that knows are one. The acting I is an object for itself, while the knowing I merely perceives other objects. In action there is no transition from the world of nature to the world of mind, for the subject has become an object to itself. Any change in the outer world is received as a perception, but every action causes such a change; therefore action is perception. (Here, as elsewhere, Schelling anticipates Gestalt psychology.) Self-determination is the primary condition of all consciousness.

JUSTICE. The object of impulse, which always acts to restore the lost identity of the self and the world, is happiness. But an impulse that transcends its proper limits acts against itself and must be prevented by a sanction not found in nature—a sanction of the will. This sanction of the will is thus the basis of justice, and the law of justice is a second nature that our will sets above the first nature.

THE NATURE OF HISTORY. The process of history is the gradual realization of law; history can be described as the development of human freedom, as an eternal progress toward the perfect state—a sovereign world federation of all sovereign states—in which all men would be citizens. Thus, history is the realization of freedom through necessity. There is an absolute identity between freedom and necessity, but this identity is forever unconscious, never the object of knowledge but always the object of faith. God is neither personal nor objective, but the revelation of the divine in man. This revelation is never complete. History is a drama in which human beings are not merely the actors, but also the authors.

ART AND AESTHETICS. If history is a drama for Schelling, nature is a work of art. Like Kant in *The Critique of Judgment*, Schelling believed that organisms and works of art are alike in that they can be properly under-

stood only teleologically; that is, as entities in which the parts serve the whole and the whole is itself purposive. The main difference between art and organisms, according to Schelling, is that in organisms the activity of the organizing intelligence lies hidden or unconscious, manifest only in the product—the organism itself; but in the work of art the productive activity is conscious whereas the product, the true art work, is unconscious and infinite. The artist never fully understands his art. The purpose of art is neither utility, nor pleasure, nor morality, nor knowledge, but beauty—the realization of the infinite in the finite.

In his aesthetics, which is elaborated in the *System des transzendentalen Idealismus* and his lectures on the philosophy of art, *Über das Verhältniss der bildenden Künste zu der Natur* (Munich, 1807), Schelling is at his most personal, his most impassioned, his most characteristic, and his most original. He held that in art, intelligence for the first time becomes completely self-conscious. In philosophy, it is abstract and limited in the expression of its potential infinity. But in art, which is completely free from abstraction in this sense, intelligence fully realizes its infinite nature. (It is pertinent that Hans Arp, the abstract artist, has written that the works usually called “abstractions” are more accurately referred to as “concretions.”) Thus art is the goal toward which all intelligence moves. Art is the true philosophy, because in it nature and history are forever reconciled; but the artist is not therefore a philosopher, since he often lacks a theoretical understanding of his own creation. The theoretical intelligence merely contemplates the world, and the practical intelligence merely orders it; but the aesthetic intelligence creates the world.

PHILOSOPHY OF IDENTITY

The third stage of Schelling's thought was the philosophy of identity, first expounded at length in *Vorlesungen über die Methode des akademischen Studiums* (Tübingen, 1803), appropriately written in Spinoza's geometric mode. Here Schelling said that the philosophy of nature and the philosophy of knowledge, taken together, constitute only half the truth and need to be completed by the other half, which unites nature and knowledge in an undifferentiated identity. The production of reality does not rest on the opposition of intelligence and nature, subject and object, but in the identity of all reality as it rises from the absolute. The absolute identity of nature and intelligence is found in their common neutral source, reason. Reason is one and infinite, embracing things-in-themselves and knowledge of things. In reason there is no

object, no subject, no space, no time. Its supreme law is the law of identity, $A = A$, which is true regardless of all spatial or temporal considerations. In the formula $A = A$, the distinction between subject and object is formal and relative. Subject and object here concern only the form, and are indifferent as to essence. It was this phase of Schelling's thought that Hegel wittily called "the night in which ... all cows are black."

PANTHEISM. The philosophy of identity was a kind of pantheism, but it stressed the aliveness of nature in contradistinction to Spinoza's dead, materialistic, deterministic pantheism. Although Spinoza's influence is evident, it is filtered through the vitalistic interpretations of Johann Gottfried Herder and Goethe and tempered by the parallel influence of Giordano Bruno's vitalistic pantheism. Schelling believed that life was the basis of the inorganic world, and not vice versa. Nature is inseparable from God, but distinguishable from him. God is not to be comprehended rationally, because his essence is will and he can be apprehended only through the will, in action. For the most part, Schelling's thought here draws from Jakob Boehme, and reintroduces Protestant mysticism into the mainstream of Western philosophy.

GOD AND EVIL. In *Philosophische Untersuchungen über das Wesen der menschlichen Freiheit* (Landshut, 1809; translated as *Of Human Freedom*, Chicago, 1936) Schelling, like Boehme, distinguishes between God as ground of being and God as perfection. Evil is explained as the ground eliciting the self-will of man in order to awaken him to the distinction between good and evil, which originally were united in one identity. Thus, evil is a necessary stage in the progress toward the total realization of good. Imperfection in being is perfection in the process of becoming. There is a dark ground or negative principle in God, but it exists so that he can become separate from it as a personality.

POSITIVE PHILOSOPHY

After 1809, the year of his first wife's death, Schelling made the given situation of existence his predominant concern. This final existentialist phase of his philosophy was first propounded in *Die Weltalter* (written in 1811 but not published in Schelling's lifetime), consummated in his lectures at the University of Berlin, and saved for posterity in three volumes, *Einleitung in die Mythologie*, *Philosophie der Mythologie*, and *Philosophie der Offenbarung*, which were published posthumously in the *Sämtliche Werke*. In these works he sought to erect a positive philosophy based on the evolution of the divine

principle in human history, especially in myths and religions, which he felt opposed and thus completed his own earlier, negative, merely rational philosophy. However, rather than representing a sharp break with his past, this last phase can be considered as the flowering of tendencies he showed as early as 1795, when he wrote, "The main function of all philosophy is the solution of the problem of the existence of the world." It is significant that while the prolific and influential writings of his first three periods were crowded into fourteen brief years, from 1795 to 1809, his last period, during which his rate of production slowed and his influence waned, lasted from 1809 to his death in 1854.

GOD. The root of existence is now found in nonbeing, in God as the ungrounded, the abyss, the eternal nothing. Only against the ungrounded can the ground arise, because nothing can become evident without resistance. Thus God is "eternal contrariety," forever alienating himself from himself. This alienation creates the possibility of the fall. As only the Absolute is real, finite things, which are not real, can exist only in a removal, in a fall from reality. The Absolute creates its own counterpart, freedom, which is both the cause of the fall and the last trace of divinity things bear after the fall. Because of this progression through opposites, Schelling called this fourth phase of his thought the opposition of negative and positive philosophy.

MAN. As the creature in whom the fall, and the state of things before the fall, both rise for the first time into consciousness, man is the crown of creation and the most interesting and rewarding object of philosophic attention. Man is free creative activity, the essence of the world. Thus, in his last phase, Schelling was led to a kind of philosophic anthropology, seeking for the essence of man in what he thought was his deepest activity, myth-making and religion. Despite the profoundly mystical flavor of his thought in this period, he still kept contact with his Kantian heritage. In *Philosophie der Mythologie* he explained mythology as a symbolic system of ideas with its own a priori structure as necessary for its functioning as, according to Kant, the a priori structure of the understanding is necessary for logical thought. Ernst Cassirer's neo-Kantian formulation of mythology as just such a conceptual structure owes a great deal to Schelling, a debt fully acknowledged in the second volume of *The Philosophy of Symbolic Forms*.

RESEMBLANCE TO EXISTENTIALISM. What has made this last phase of Schelling's thought most apposite to

modern existential philosophy is another question rising from his consideration of man's being in the world. As he put it, "Just he, man, impelled me to the final desperate question: Why is there anything at all? Why not nothing?" It is this question, described as "dreadful" rather than "desperate," that Martin Heidegger took for his central theme in *Being and Time*.

Schelling's resemblance to the modern existentialists is suggestive rather than substantive, but the suggestion is inescapable. Like them, he emphasized that philosophy must deal not only with the "what" of the world, which explains its nature, but also with the "that" of the world—the fact of its existence, of its being there. And like Søren Kierkegaard (who attended some of his lectures in Berlin but was not impressed), Friedrich Nietzsche, Heidegger, and Jean-Paul Sartre, Schelling tried to express the inexpressible pathos of existence in oracular utterances halfway between poetry and metaphysics, the quality of which can be conveyed only by quotation. The world and God have as common ground "the incomprehensible basis of reality." "Existence is self-affirmation." God is "the infinite affirmation of himself." The objective world is the unconscious poetry of the spirit creating itself. Finally, there is a striking formulation of the existential anxiety, which is also an anticipation of the psychoanalytic doctrine of resistance: "The philosopher who knows his calling is the physician who . . . seeks to heal with gentle, slow hand the deep wounds of human consciousness. The restoration is all the more difficult since most people do not *want* to be healed at all and, like unhappy patients, raise an unruly outcry if one even approaches their wounds."

So the problems posed by Schelling in the nineteenth century are still very much alive in the philosophic and literary world of today. At that time his main influence in England was in aesthetics, and his lectures on the philosophy of art were translated as *The Philosophy of Art* in 1845. The continuing, perhaps growing contemporary interest in him is demonstrated by the fact that the first translations into English of any of his books since then—significantly, both from his last, existentialist phase—were published in America in 1936 and 1942.

Bibliography

WORKS BY SCHELLING

- Grundlegung der positiven Philosophie. Münchener Vorlesungen WS 1832/33 und SS 1833*, edited by H. Fuhrmans. Turin: Bottega d'Erasmus, 1972.
- Einleitung in die Philosophie*, edited by W. E. Ehrhardt. Stuttgart: Fromman-Holzboog, 1989.

System der Weltalter, edited by S. Peetz. Frankfurt: Klostermann, 1990.

Urfassung der Philosophie der Offenbarung, edited by W. E. Ehrhardt. Hamburg: Meiner, 1992.

Collected Works

Sämtliche Werke. 14 vols, edited by K. F. A. von Schelling. Stuttgart and Augsburg: Cotta, 1856–1861.

Werke. 8 vols, edited by M. Schröder. Munich, 1927–1956.

Translations

The Ages of the World. Translated by F. de Wolfe Bolman. New York: Columbia University Press, 1942. Translation of *Über die Gottheiten von Samothrake*, Stuttgart and Tübingen, 1815, a part of *Die Weltalter*, which is mentioned in the text. *The Ages of the World* includes a long, informative introduction on Schelling's philosophy, especially its last phase.

Of Human Freedom. Translated by J. Gutmann. Chicago: Open Court, 1936. Translation of *Philosophische Untersuchungen über das Wesen der menschlichen Freiheit*.

The Philosophy of Art: An Oration on the Relation between the Plastic Arts and Nature. Translated by A. Johnson. London: Chapman, 1845. Translation of *Über das Verhältniss der bildenden Künste zu der Natur*.

System of Transcendental Idealism. Translated by P. Heath. Charlottesville: University Press of Virginia, 1978.

The Unconditional in Human Knowledge: Four Essays, 1794–1796. Translated by Fritz Martl. Lewisburg, PA: Bucknell University Press, 1980.

Bruno, or On the Natural and the Divine Principles of Things. Translated by Michale Vater. Albany: State University of New York Press, 1984.

Ideas for a Philosophy of Nature: An Introduction to the Study of This Science. Translated by E. E. Harris and Peter Heath. Cambridge, U.K.: Cambridge University Press, 1988.

On the History of Modern Philosophy. Translated by Andrew Bowie. Cambridge, U.K.: Cambridge University Press, 1994.

WORKS ON SCHELLING

Beach, E. *The Potencies of God(s): Schelling's Philosophy of Mythology*. Albany: State University of New York Press, 1994.

Bowie, A. *Schelling and Modern European Philosophy*. London: Routledge, 1993.

Bréhier, Émile. *Schelling*. Paris: Alcan, 1912.

Cassirer, Ernst. *Das Erkenntnisproblem in der Philosophie und Wissenschaft der neueren Zeit*, Vol. III: *Die Nachkantischen Systeme*. Berlin: Cassirer, 1920. Includes a comprehensive, clear, and sympathetic account of Schelling's epistemology.

Copleston, Frederick C. *History of Philosophy*. Vol. VII. London, 1963. Includes the best account of Schelling's philosophy in English.

Courtine, J.-F. *Extase de la raison: Essais zur Schelling*. Paris: Galilée, 1990.

Esposito, J. *Schelling's Idealism and Philosophy of Nature*. Lewisburg, PA: Bucknell University Press, 1977.

Fischer, Kuno. *Geschichte der neueren Philosophie*. Vol. VII. 3rd ed. Heidelberg, 1902. Probably the best full-length study of Schelling's life and work.

Frank, M. *Der Unendliche Mangel am Sein: Schellings Hegelkritik und die Anfänge der Marxschen Dialektik*. Frankfurt: Suhrkamp, 1975.

- Hartmann, Nicolai. *Die Philosophie des deutschen Idealismus*. 2nd ed. Berlin, 1960. An exhaustive and authoritative work on German idealism.
- Heidegger, M. *Schelling's Treatise on the Essence of Human Freedom*. Athens: Ohio University Press, 1985.

SCHILLER, FERDINAND CANNING SCOTT (1864–1937)

Ferdinand Canning Scott Schiller, the British pragmatist philosopher, was born in Schleswig-Holstein and studied at Rugby and at Balliol College, Oxford. After teaching German at Eton, he returned to Oxford for his MA. In 1893 he went to Cornell University as an instructor and graduate student. In 1897, without receiving a doctorate, he returned to Corpus Christi College, Oxford, where he was successively assistant tutor, tutor, senior tutor, and fellow and where he received a DSc in 1906. He served as

treasurer of the Mind Association and president of the Aristotelian Society (1921), and he was elected a fellow of the British Academy in 1926. From 1926 on, Schiller spent part of each year at the University of Southern California as visiting lecturer and then as professor; in 1935 he moved there permanently.

PRAGMATISM

Schiller's views, which he called at various times humanism, voluntarism, and personalism, as well as pragmatism, were strongly influenced by William James; and Schiller paid James great tribute, although he claimed to have arrived at his opinions independently. There was, however, an important difference of emphasis between them: James stressed the purposive aspect of thinking, and Schiller, the personal. James also accepted the independence of what is objectively given, whereas Schiller regarded all knowledge, even of "facts," as relatively subjective. Both Schiller and John Dewey were strongly influenced by G. W. F. Hegel and took the process of knowing as central to reality, but the influence of idealism was much stronger on Schiller than on Dewey. And whereas Schiller pursued the subjective and individual aspects of James's psychology, Dewey built upon its objective and social aspects. C. S. Peirce thought that Schiller's philosophy was intermediate between James's and his own.

Schiller's views may best be understood in terms of his opposition to the dominant absolute idealism of the British Hegelians, F. H. Bradley (Schiller's particular *bête noire*), J. M. E. McTaggart, Bernard Bosanquet, and T. H. Green. To Schiller the absolutism, monism, authoritarianism, rationalism, and intellectualism that these thinkers espoused ignored the basic insight of Protagoras that man is the measure of all things.

Schiller was convinced that all acts and all thoughts are irreducibly the products of individual human beings and therefore inescapably associated with the needs, desires, and purposes of humans. Such terms as *reality* and *truth* denote nothing complete and absolute; rather, they are intertwined with human intentions and deeds. Schiller emphasized the effective creativity of the human mind in organizing the universe of human experience and thus in making or remaking "reality." Man makes his truth along with his other values, Beauty and Goodness. Our axioms are never God-given but are human-made; they are not a priori verities but postulates, or working hypotheses, whose truth grows or diminishes within our experience. The logic we employ in gathering knowledge is dynamic and functional rather than eternally fixed. Our data are not "the given" but "the taken." Thus, in

Schiller's view, human activity is focal both to epistemology and to metaphysics, and there is genuine novelty in our growing universe and no theoretical limit to human freedom.

MAKING REALITY

The absolute idealists maintained that reality is a seamless logical unity, not a mere disjointed plurality; that in the Absolute all separateness vanishes; that nothing finite, nothing that changes, is ever quite real, not even human personality; and that there is something makeshift, transitory, and unsatisfactory about the bits of matter we see, the individual acts we perform, and the private thoughts we think. But, Schiller pointed out, that is all that exists for us. An independent or absolute reality that does not enter into our experience, or explain our knowledge, is irrelevant to us. "Reality" for us is piecemeal, incomplete, and plastic. It is idle to ask "What is real?" Rather, the only question we can answer is "What can I know as real?"

The reality revealed by our actual active procedures of knowing is not rigid but malleable, not completed but evolving. Because it responds, at least to some extent, to our working and probing, it must somehow be not unrelated to our needs and purposes. The process of knowing, Schiller said, is "never one of bringing the mind into relation with a fundamentally alien reality, but always one of improving and extending an already existing system which we know." What we call real is that which, for our own reasons, we evaluate as important. It is the result of the kind of selection by which we reduce the chaos about us to order.

Schiller's critics found intolerable the thesis that we make reality. Bertrand Russell, for example, wrote, "Dr. Schiller says that the external world was first discovered by a low marine animal he calls 'Grumps,' who swallowed a bit of rock that disagreed with him, and argued that he would not have given himself such a pain, and therefore there must be an external world. One is tempted to think that ... many people ... had not yet made the disagreeable experience which Grumps made. Meanwhile, whatever accusations pragmatists may bring, I shall continue to protest that it was not I who made the world" ("Professor Dewey's 'Essays in Experimental Logic,'" *Journal of Philosophy* 16 [January 1919] 26).

Schiller found it hard to meet two particular objections to the theory of the making of reality: The world obviously preceded the existence of humans, and there are patent limits to human powers. In his later writings Schiller therefore reluctantly accepted the distinction between "finding" and "making" the real, although he

reiterated the meaninglessness of the "real-as-it-is-in-itself." He revived the Greek term *hyle* to refer to the indeterminate, formless chaos, to whatever may be beyond man's ability to perceive or manipulate, to the raw malleable material of the cosmos.

Despite its drawbacks, the doctrine of the making of reality provided Schiller with the basis for certain important conclusions. In his view, it provided a perfect accommodation for Darwinian evolution; it supported a belief in the existence of genuinely new things and situations (always a problem for the absolute idealists because they regarded reality as a self-contained whole); it legitimized human progress; it provided a suitable conceptual scheme for the view, which Schiller ascribed to Albert Einstein and other scientists, that to posit "the real" independently of our sensations is to make an intellectual construction; and, most significantly, it was a firm foundation for man's freedom.

OTHER METAPHYSICAL VIEWS

Schiller's other metaphysical views may be briefly stated. The function of philosophy, he thought, was to preserve the grand synoptic vision, to be an ultimate synthesis of the special sciences. Metaphysical systems, he held, are quasi ethical, or even aesthetic, in character; they reflect personality and temperament. Because the individual human person was an ontological ultimate for Schiller, he was a personalistic pluralist. He was also a hylozoist, asserting that all matter is more or less alive.

TRUTH

Many theories of truth have been propounded through the centuries, but none has been entirely satisfactory. Schiller pointed out the shortcomings of some, particularly the correspondence and coherence theories. Pragmatists agree that no statement wears its truth like a badge; its truth can be determined only by what follows from it in the course of experience. Truth is only a potential, a valuation applied as the result of a procedure called verifying, or making true. Truth is relative to the evidence and to the purpose of the investigator; no degree of verification will ever establish the absolute truth of a statement. Schiller held that truth is personal and particular, dynamic and progressive, not eternal or absolute but the best solution found so far for any problem. That which thwarts or defeats the purpose of an inquiry we call false; that which furthers it we call true. "Truth is that manipulation of [objects] which turns out upon trial to be useful, primarily for any human end, but ultimately for that

perfect harmony of our whole life which forms our final aspiration" (*Humanism*, p. 61).

Nevertheless, Schiller thought the conversion of "The truth is useful" to "The useful is true" to be malicious. Therefore, in Chapter 8 of *Logic for Use* he distinguished seven kinds of truth claims. (1) A postulate is a statement that is "desirable if true," whose truth we try to establish. (2) "A fully verified postulate which serves as principle for a fully established science" and "rests securely on the solid mass of scientific fact it has been instrumental in eliciting" is an axiom. (3) A methodological assumption (determinism, for example) is any guiding principle that appears to be useful in analyzing the flux of events. (4) An assumption of limited usefulness, such as the use of Euclidean geometry in cartography, is a methodological fiction. Finally, truth claims may be, or are, made in (5) fictions, (6) jokes, and (7) lies. Lies are deliberately untrue but may be useful, as in propaganda.

Thus, Schiller held, to claim that all truths work for us in some way and that there is no useless knowledge is far from saying that whatever is useful is true. However, he was aware of difficulties concerning the status of past truth, the usefulness of some parts of pure mathematics, and such questions as whether truth is equivalent to survival value or to social acceptance.

LOGIC

Since the true is what is true for us as seekers for it, Schiller deplored the divorce of logic from the empirical sciences and from psychology. He criticized traditional formal logic for having been a word game and for having been allied to metaphysics rather than to the empirical sciences and to psychology. For Schiller, as for Dewey, thought arises as an element in the solution of a problem. Thus the activity of reasoning has a biological matrix, and it is conditioned by such factors as interest, purpose, emotion, and satisfaction. Schiller was concerned with showing that meanings had been misunderstood and ignored by logic. Meanings, he pointed out, are acquired only in use; they are plastic and personal, and they occur only in contexts. Traditional logic regarded them as purely verbal and as fixed; it believed that one meaning corresponded to one form, and vice versa.

Schiller thought that logic had made the two mistakes of "etherealizing" and "depersonalizing" truth. In its search for formal validity, it had made three fatal abstractions; from actual thinking processes (psychology); from purpose, truth, or utility; and from meaning, matter, and context. In two books, *Formal Logic* (1912) and *Logic for Use* (1929), Schiller made an exhaustive study of formal

logic, including terms, propositions, definitions, the syllogism, and fallacies. He showed that, even on its own terms, logic was not free from ambiguity—how can there be novelty in the conclusion of a syllogism? What is the precise import of the copula in a proposition? Moreover, logic appealed at several crucial points to such psychological notions as the "necessity" of implication and the "certainty" or "self-evidence" of propositions. Schiller thought that logic should become a systematic evaluation of actual knowing, a study continuous with the sciences. His resolute experimentalism led him to assert, in "Axioms as Postulates" (1902), that even the laws of thought (identity, contradiction, excluded middle) are not principles of being or rules of logic but postulates.

SCIENTIFIC METHOD

In analyzing the procedures of science, Schiller made several noteworthy contributions. He showed that the concept of "fact" is ambiguous. The "facts" of the scientist are the result of a process of selection, segregation, and evaluation; they are relative to the state of the science, the methods and instruments used, and the aims and bias of the scientist. They are also relative to the hypothesis used, to our own senses, to our memory, and to our words. Schiller also said, "The impossibility of 'breaking' a Law of Nature proves nothing but our determination to uphold a phraseology we have found convenient" (*Formal Logic*, p. 328).

ETHICS AND RELIGION

Schiller carried his pragmatic approach into ethics and religion. There are no abstract values, he said, but only acts of personal valuation. Moral principles are not a priori presuppositions of right conduct; they are its results. The statements of religion are likewise postulates. (James spoke of the will to believe; Schiller, of the right to postulate.) God is a pervasive principle of goodness, not infinite but finite, struggling to develop; the actions of men therefore make a difference. Man's freedom is correlative to the postulate that man is responsible for his acts and is an agent in the full sense of the term. Schiller shared with James and Henri Bergson an interest in psychical research that stemmed from his desire to examine the methods of science at its periphery and from his postulate of immortality. Schiller was also keenly interested in eugenics. This led him to oppose democracy as a "sham" (*Problems of Belief*, p. 81) and to praise the British fascist Oswald Mosley. His social opinions were generally regarded by his philosophic supporters as a vagary.

Schiller was a prolific writer, a sprightly stylist, and a spirited polemicist who maintained a role of philosophic *enfant terrible* through hundreds of essays and books. He edited and wrote most of a parody of *Mind*, which he called *Mind!*—one of the rare examples of philosophic humor.

See also Humanism.

Bibliography

Schiller's major books are two collections of essays, *Humanism: Philosophical Essays* (London and New York: Macmillan, 1903) and *Studies in Humanism* (London and New York: Macmillan, 1907). Two later collections are *Must Philosophers Disagree?* (London: Macmillan, 1934) and *Our Human Truths* (New York: Columbia University Press, 1939).

His major works in logic are *Formal Logic: A Scientific and Social Problem* (London: Macmillan, 1912) and *Logic for Use: An Introduction to the Voluntarist Theory of Knowledge* (London: G. Bell, 1929).

His essay "Axioms as Postulates" appeared in the anthology *Personal Idealism*, edited by Henry Sturt (London: Macmillan, 1902), pp. 47–133. An early, prepragmatic metaphysics, titled *Riddles of the Sphinx* and written under the pseudonym of A. Troglodyte (London and New York, 1891), was offered unsuccessfully to Cornell University as a PhD thesis. The essays "Scientific Discovery and Logical Proof" (1917) and "Hypothesis" (1921) were contributed to *Studies in the History and Method of Science*, edited by Charles J. Singer (Oxford: Clarendon Press, 1917–1921), and may be found in Vol. I, pp. 235–289, and Vol. II, pp. 414–446, respectively. Another work by Schiller is *Problems of Belief* (London: Hodder and Stoughton, 1924).

A critical study of Schiller's philosophy, with an exhaustive bibliography, is Reuben Abel, *The Pragmatic Humanism of F. C. S. Schiller* (New York: King's Crown Press, Columbia University, 1955).

See also Reuben Abel, ed., *Humanistic Pragmatism; The Philosophy of F. C. S. Schiller* (New York: Free Press, 1966); and *A Bibliography of the Works of F. C. S. Schiller, with an Introduction to Pragmatic Humanism* (San Diego, CA: San Diego State College Press, 1969).

SCHILLER, FRIEDRICH (1759–1805)

Friedrich Schiller, a famed dramatist, poet, and essayist, was born in Marbach, a small town in southwest Germany, to Elisabeth Kodweiss and Johann Kaspar Schiller, a lieutenant in the army of the Duke of Württemberg. Though tutored in Latin at an early age by his local pastor to prepare him for theological studies, Schiller was

mandated by the duke to attend the duke's new military academy, Karlsschule. Schiller later related how his rebellion against the suffocating rigidity and isolation of Karlsschule paradoxically fostered his love of poetry. He remained at the school for eight years, focusing first on law, then on medicine. After his second medical dissertation, "On the Connection of the Animal Nature of Man with his Spiritual Nature," was accepted, he became a regimental physician in Stuttgart. There, he completed his first drama, *The Robbers*, the staging of which a year later (1782) in Mannheim brought him immediate acclaim and confirmation of his literary gifts. When the duke forbade him to write anything but medical treatises, Schiller fled Württemberg. For most of the rest of his life he would suffer considerable financial hardship and extremely poor health. Nevertheless, from 1782 to 1787 he managed to complete three plays (*Fiesco*, *Intrigue and Love*, and *Don Carlos*), to compose several poems (e.g., "Ode to Joy") and essays (e.g., "Theater Considered as a Moral Institution" and "Philosophical Letters"), and to found the journal *Rheinische Thalia*—all of which helped cement his reputation as a member of the *Sturm und Drang* (Storm and Stress) literary movement of the time.

While Schiller's literary output as a critic continued unabated in the ensuing years, his attention over the next decade (1787–1796) turned from the stage to the study of history and to an increasing preoccupation with philosophical treatments of morals and the arts. His *History of the Revolt of the Netherlands* (1787), which celebrated religious tolerance, won him a professorship (albeit unsalaried) in history at the University of Jena in 1789, and over the next two years he produced the enormously successful *History of the Thirty Years War*. His inaugural lecture, "What Does 'Universal History' Mean and to What End Is It Studied?" (1789) contains reflections, fairly conventional at the time, on history's progressive character. This progressive view of history collided, however, with a longing for a lost harmony that he thought art alone can provide (compare his nostalgic elegy of 1788, "The Gods of Greece," with his stirring, forward-looking call to his caste in the 1789 poem "The Artists").

This collision converged with a burgeoning interest in Immanuel Kant's moral and aesthetic writings. Following his marriage to Charlotte von Lengefeld in 1790 and an almost fatal bout with pneumonia a year later, Schiller was given the opportunity to pursue these interests in earnest thanks to a three-year pension provided by Prince Friedrich Christian von Schleswig-Holstein-Augustenburg of Copenhagen. Over the next four years Schiller composed several essays on aesthetics. The organ for

many of these essays was the journal *Die Horen*, founded by Schiller with the help of many of the leading figures in German letters at the time, among them Johann Wolfgang von Goethe and Wilhelm von Humboldt, with whom Schiller developed close friendships that had a lasting influence on his work.

Following this academic and philosophical interlude, and with Goethe's increasing encouragement, Schiller turned his attention back to the theater where he crowned his fame as a playwright with several historical plays: the *Wallenstein* trilogy (1798–1799), *Maria Stuart* (1800), *The Maid of Orleans* (1801), *The Bride of Messina* (1802), and *Wilhelm Tell* (1804).

CRITICAL APPROPRIATION OF KANT'S PHILOSOPHY

Though philosophical concerns are apparent in Schiller's earliest publications, he makes his most influential philosophical contributions in essays composed between 1792 and 1796. The common feature of the first group of these essays is their critical engagement with Kant's philosophy. The aborted project of the "Kallias-Letters" (1793; published 1847) attempts in Kantian terms to establish something Kant declared impossible: "an objective concept of beauty" and, indeed, one that unites the realms of nature and freedom. In the "Kallias-Letters" Schiller accordingly construes beauty as "freedom in the appearance" of something, an appearance that is the natural or artistic, dynamic counterpart to moral autonomy. In "On Grace and Dignity" (1793) Schiller takes further aim at Kant's dualism, in particular, his account of an obligatoriness that is independent of grace ("the expression of a beautiful soul, where sense and reason harmonize").

Schiller's remarks provoke an exchange of letters and a public response in Kant's *Religion within the Limits of Reason Alone* (1793), where Kant suggests that any apparent disagreement can be resolved by distinguishing duty, the dignity of which is necessarily independent of grace, from virtue, which is not. Though Schiller accepts the suggestion in correspondence with Kant, he ultimately finds the distinction unpersuasive. Nevertheless, Schiller utilizes themes from Kant's aesthetics to develop a conception of tragedy in other essays from this period, notably, "On the Reason for Taking Pleasure in Tragic Subjects" and "On the Art of Tragedy" in 1792 and "On the Pathetic" in 1793. In particular, in Kant's notion of the dynamically sublime, the aesthetically pleasing displays of human beings' moral capacity to defy nature's otherwise all-powerful sway over them, Schiller finds the key to explaining the point of tragedy, though he invests art with

a purpose beyond the confines of Kant's aesthetics. As Schiller puts it in the opening lines of "On the Pathetic," "Portrayal of suffering—as mere suffering—is never the end of art, but as a means to this end it is of the utmost importance to art. The ultimate purpose of art is to depict what transcends the realm of the senses and the art of tragedy in particular accomplishes this by displaying morality's independence, its freedom, in the throes of passion, from nature's laws" (1993 [1793] p. 45).

THE AESTHETIC LETTERS

Schiller's most influential work on aesthetics is *On the Aesthetic Education of Man in a Series of Letters* (1795). In this work (hereafter *Letters*) Schiller frames an argument for the necessity of an aesthetic education against the backdrop of a dire assessment of contemporary culture. Echoing Jean-Jacques Rousseau and anticipating Karl Marx, the assessment emphasizes the stupefying fragmentation and lifeless mechanism of society. Still, neither reason nor politics, Schiller argues, provides an answer to humanity's plight. The French Revolution had demonstrated only too well the failure of political reform without a moral transformation of the citizenry, that is, a transformation of individuals into citizens. As for reason, if it is the answer, Schiller asks, why in an "enlightened age" are we still barbarians? With art as the sole remaining alternative Schiller announces his central thesis, "If man is ever to solve the problem of politics in practice he will have to approach it through the problem of the aesthetic, because it is only through beauty that man makes his way to freedom" (1993 [Letter 2, 1795], p. 90). Though Schiller sometimes (e.g., Letter 14) ascribes freedom and morality solely to the rational side of human nature, the overriding sense of freedom at work in the *Letters* is freedom as self-mastery, equally liberated from the tyranny of nature and the tyranny of ideas. (In a footnote to Letter 19 Schiller acknowledges the possible misunderstandings caused by these two notions of freedom.)

Though the example set by the Greeks, Schiller submits, provides reason not to despair, he is well aware that experience and the historical record seem to speak volumes against the thesis. Still, they do so only if there is no transcendental path to a nonempirical, purely rational concept of beauty. Schiller accordingly proposes just such a path that takes its bearings from "the sheer potentialities" of human nature, potentialities that he juxtaposes with "what is absolute and unchanging" and the "necessary conditions" of human life. Though he feels no need to justify the considerable presuppositions built into this precarious move, what no doubt justifies it in his mind is

a fundamental analogy running throughout the *Letters*, namely, the analogousness of individual and political self-production to artistic production. In each case the reality in question can be conceived as the product of shaping something natural provided by experience, according to an idea that is, at least in regard to the initiative in question, irreducible to the respective experience of nature.

On the basis of this same analogy, the integrity of the reality (the production) in question demands that both nature and the idea—or, analogously, feeling and principle, the human condition and the human person—be given their due. Corresponding to this dual necessity are two basic laws of human nature, namely, “to externalize all that is within it, and give form to all that is outside it,” and two basic drives: a sensuous drive toward the material content of individual, momentary sensations, and a formal drive toward freedom in the form of universal, eternal laws. While the sensuous drive acts as a physical constraint and the formal drive as a moral constraint, the “task” of culture, Schiller submits, is to amplify each drive to the point where they have a moderating effect on one another. Departing from Kant and appropriating Johann Gottlieb Fichte’s accounts of a dialectical unity, Schiller declares that freedom requires, not the subordination of one drive to the other, but their coordination.

Schiller acknowledges the utopian character of the task. Still, he submits that there are moments in life when feeling and thinking merge, when human beings are able to realize both drives in a complementary way. These are the moments when human beings play. As Schiller famously puts it, “[M]an only plays when he is in the fullest sense of the word a human being, and he *isonly fully a human being when he plays*” (1993 [Letter 15, 1795] p. 131). (In Letter 27 Schiller gives a genealogy of play, from the physical play of an overflowing nature to the free play of human fantasy and association, culminating in aesthetic play with the capacity to transform sexual desire.) The play drive, as Schiller calls it, reconciles the otherwise competing sensuous and formal drives through its preoccupation with an object that combines their respective objects, life and form. In this way Schiller introduces his definition of beauty as a living form that is the object of the play drive. Precisely by yielding these moments of play, beauty is both a regenerative means to and a symbol of the consummate freedom that is, in his eyes, the destiny of humankind. Beauty here is not an empty (purposeless) form and the experience of it is not merely a matter of taste or the play of human faculties. Instead, it is a living form that embodies in a concrete, autonomous way the unity of feeling and principle, of

sense and reason. So conceived, beauty has a vitality that transcends human subjectivity without leaving it behind and yet, for this reason, holds an incomparable historical promise for humanity.

The already mentioned tension in Schiller’s conception of moral freedom takes on a new twist as Schiller describes freedom as the point where the sensuous and rational drives, far from being coordinated and facilitated, are said to be “canceled” (Letter 19). Further complicating matters, he gives an account of an “aesthetic condition” as a necessary means of predisposing human beings to a moral condition, “Man in his *physical* condition merely suffers the dominion of nature; he emancipates himself from this dominion in the *aesthetic* condition, and he acquires mastery over it in the *moral*” (1993 [Letter 24, 1795] p. 156). Still, if the aesthetic condition is now depicted as necessary for the transition to morality, its necessity is not something that one can leave behind. Beauty continues to be living proof “that a human being need not flee matter in order to manifest herself as spirit” (1993 [Letter 25, 1795], p. 165).

The transition from the aesthetic condition to the moral condition is supposedly far easier than the transition to the former from the physical condition. Hence, Schiller devotes his final remarks (Letters 26–28) to the role of “aesthetic semblance” in the former transition. Basic needs must be met, he notes, before aesthetic semblance can be indulged, though such indulgence is also a natural development of seeing and hearing. These two senses do not simply receive but help produce their objects. In the process, the play-drive develops, as people find enjoyment in mere semblance, as does the mimetic drive to shape and form this or that semblance into something relatively self-sufficient (though only relatively since it is a human product and subject to human dictates). As these drives develop, the realm of beauty expands but also gives further definition to the boundaries between semblance and reality. Moreover, only in this world of semblance does the artist enjoy sovereign rights. What makes the artist an artist and renders semblance aesthetic is a certain honesty (no pretense of being real) and autonomy (dispensing with all support from reality).

In the end, the aesthetic semblance is self-reflexive and self-redeeming. In an important respect art is the semblance of semblance, the illusion of illusion. The aesthetic education overturns a deficient, actual stage of human nature because art is capable of articulating ever higher human possibilities. Moreover, these are possibilities at the crossroads of the individual and the species. In

contrast to a strictly private sensual pleasure the enjoyment of semblance is a pleasurable activity that is inherently shareable, though not through some dictate of a *volonté générale*. Herein lies yet another side to the promise of beauty discussed earlier. Only in an aesthetic state (*Staat*) can we confront each other, not as enforcers of our respective rights (“the fearful kingdom of forces”) or as executors of our wills (“the sacred kingdom of laws”), but as free and equal citizens, “the third joyous kingdom of play and of semblance” (1993, [Letter 27, 1795], p. 176).

POETS, PHILOSOPHY, AND PSYCHOLOGY

While Schiller concentrates in the *Letters* on art’s prospects of overcoming modernity’s alienating effects on humanity at large, his final major study, *On Naive and Sentimental Poetry* (1795–1796), turns to those effects on writers themselves. Naive poets, typified by ancient authors such as Homer, write effortlessly in a straightforward way without intruding themselves onto the scene, whereas “sentimental” (self-conscious) poets, so typical among modern writers like Ariosto, express their feelings about the scenes they depict. Characterizing the difference in terms of nature, Schiller explains, “The poet either is nature or will seek it. The former constitutes the ‘naive,’ the latter the ‘sentimental’ poet” (1993 [1795], p. 200). Thus, sentimental poets, in contrast to naive poets, are acutely aware of the difference between reality and their ideas and idealizations. Thus conflicted in their mode of feeling, they either mock reality in pathetic or playful satires, mourn the absence or loss of the ideal in elegies, or—most difficult of all—celebrate its future realization in idylls. Schiller’s use of the terms *naive* and *sentimental* is idiosyncratic; *naive* does not mean simplistic but direct, and *sentimental* does not mean maudlin but reflective.

Moreover, he construes the difference between these notions at times historically, at other times theoretically, to designate antithetical kinds of poetic consciousness in some contexts, and contrary traits within a single poet in others. For example, Goethe is a modern naive poet who is nonetheless capable of treating a theme “sentimentally,” as in his 1774 novel *Sorrows of the Young Werther*. (The contrast between naive and sentimental is in fact motivated, some argue, by Schiller’s attempt to come to terms with what he takes to be the difference between Goethe’s natural genius and his own more reflective, labored approach to writing.)

Nevertheless, in the first two parts of the essay, Schiller manages to accord each of these divergent literary

modes its due, while conceding “that neither the naive nor the sentimental character, considered in itself, can completely exhaust the ideal of beautiful humanity, an ideal that can only emerge from the intimate union of both” (1993 [1796], p. 249). That union itself is, Schiller adds, present only in “a few, rare individuals” since the difference between the naive and the sentimental poet is, he maintains, rooted in a broader difference as old as culture itself. Accordingly, in the third and final part of the essay, Schiller inscribes the difference between naive and sentimental poetry in a psychological profile of the difference between realists and idealists, that is, those who allow themselves to be determined in the end by nature or reason, respectively, be it in the form of the competing theoretical demands of common sense and speculation or the rival practical demands of happiness and nobility.

In “Concerning the Sublime” (first published in 1801 but begun around 1795) Schiller argues that sublimity must come to the aid of beauty in completing an aesthetic education, not least because nature’s intransigence defeats philosophy’s attempts to bring “what the moral world *demands* into harmony with what the real world *does*” (1993 [1801], p. 81). According to some critics, besides signaling a departure from the more optimistic (idealist) chord struck in the *Letters* and even the vestiges of a rationalist idea of harmony in *Naive and Sentimental Poetry*, this emphasis on philosophy’s limitations, with the grounding of realism and idealism in a “psychological antagonism,” explains why Schiller’s philosophical reflections on art largely come to a halt and he turns his attention once again to the stage. (One particularly noteworthy exception is the criticism of naturalism in the preface to the book version of the *Bride of Messina* in 1803, titled “On the Use of the Chorus in Tragedy,” an essay utilized by Friedrich Nietzsche in *The Birth of Tragedy* in 1871).

The influence of Schiller’s writings on German idealists and romantics is enormous. Shortly after the appearance of the *Letters*, Georg Wilhelm Friedrich Hegel writes Schelling that they are a “masterpiece,” and Johann Christian Friedrich Hölderlin makes plans to write his own “New Letters” on the same topic. Shaken in his neoclassicist beliefs by Schiller’s deft counterpoint of naive and sentimental poetry, Friedrich von Schlegel famously reconstrues them as “Classical” and “Romantic” poetry. Twenty years later, in his lectures on aesthetics, Hegel pays tribute to Schiller’s “great service of having broken through the Kantian subjectivity and abstraction and having dared to go beyond it, grasping unity and recon-

ciliation as the truth intellectually and realizing it artistically” (Hegel 1970 [1835], p. 89).

SCHLEGEL, FRIEDRICH VON (1772–1829)

Friedrich von Schlegel, a critic and philosopher, whose writings spearheaded early German Romanticism, started out as a devotee of Greek poetry. Born to an illustrious literary family in Hanover and classically trained, Schlegel was an unhappy and unfocused student of law at Göttingen and Leipzig from 1790 to 1793, all the while piling up enormous gambling debts. Fleeing creditors and abandoning his legal studies, he moved in 1794 to Dresden where, inspired by Caroline Böhmer, his future sister-in-law, he launched his literary career with essays extolling

ancient poetry’s superiority to modern poetry. In “On the Study of Greek Poetry” (completed 1795, published 1797), he echoes Johann Joachim Winckelmann by attributing the greater unity, objectivity, and naturalness of ancient works to the Greeks’ single-minded pursuit of idealized beauty.

PHILOSOPHY, CRITICISM, AND THE ROMANTIC TURN

Schlegel eventually wrote the *History of the Poetry of the Greeks and Romans*, but by the time the only volume was published in 1798, his view of modern poetry had changed. Already in his 1795 essay his admiration for William Shakespeare seems to belie his insistence on Sophocles’ superiority. His politics, too, though inspired by the ancients, were decidedly unconventional, as evidenced by his defense of the legitimacy of insurrection in his “Essay on the Concept of Republicanism” (1796), itself a critical review of Immanuel Kant’s “Toward Perpetual Peace” (1795). But it was chiefly Friedrich Schiller’s *On Naive and Sentimental Poetry* (1795–1796)—with its balanced judgment of the comparable virtues of ancient, “naive” and modern, “sentimental” (self-conscious) poetry and its reference to an even loftier poetry—that challenged Schlegel to reconsider his earlier views. Also like Schiller, Schlegel began to embrace Johann Gottlieb Fichte’s dialectical vindication of human dignity in the face of the threats posed to it by empiricism and mechanistic materialism. A growing awareness of Fichte’s impoverished view of nature eventually tempered this enthusiasm. Contrasting the “consistent empiricist” for whom everything sacred is “nonsense” with “mystics” as the real source of philosophy, Schlegel declares “Spinoza the best mystic known to us before Fichte” (*Kritische Ausgabe*, Vol. 18, p. 5). At the close of the eighteenth century Schlegel searched, much like Schelling and Georg Wilhelm Friedrich Hegel, for a philosophical path combining Benedict (Baruch) de Spinoza’s pantheistic naturalism with Fichte’s idealism.

Still, neither in Spinoza nor in Fichte did Schlegel find the sort of historical sensibility already exhibited in his early neoclassicist phase. This sensibility was accentuated in 1796 when, further signaling his departure from classicism, Schlegel begrudgingly accepted Kant’s argument that there are no objective rules for aesthetic judgments. Schlegel proposed that critics compensate for this lack of rules by being as comprehensively informed as possible of not only a writer’s but also an entire culture’s literary repertoire. At the same time he insisted that “criticism compares a work with its own ideal” (*Literary Note-*

books, p. 1135). This joint concern for a work's context and its sui generis character (exemplified by Schlegel's essays on Friedrich Heinrich Jacobi's *Woldemar* [1779], Georg Forster's works, and Gotthold Ephraim Lessing in 1797) would profoundly influence the development of hermeneutics by Wilhelm Dilthey and others.

In 1797 Schlegel moved to Berlin where close friendships with Friedrich Daniel Ernst Schleiermacher, Johann Ludwig Tieck, and Novalis (Friedrich Leopold von Hardenberg) gave rise to the new literary and philosophical movement eventually known as Romanticism. Its chief organ, the journal *Athenäum*, edited by Schlegel and his brother, August Wilhelm, contained Schlegel's most influential contributions to Romantic theory: "Fragments" and an essay on Johann Wolfgang von Goethe's *Wilhelm Meister* in 1798, and "Ideas" and "Dialogue on Poetry" in 1800. Another important source for Schlegel's theory is "Critical Fragments," printed in Johann Friedrich Reichardt's *Lyceum der schönen Künste* (1797). The form of fragments is itself a testament to the new theory's defiance of traditional literary theory. In memorable fashion Schlegel contrasts "Classical" with "Romantic" poetry, which disregards the traditional insistence on preserving purity of genre (epic, drama, and lyric). The novel (*Roman* in German) is, at least at first, paradigmatic for this theory that applauds the highly imaginative, genre-mixing fantasies (often with a love interest) typified by such Romance language writers as Dante Alighieri, Petrarch, and Miguel de Cervantes (but also by Shakespeare). In 1799 Schlegel provides his own example of a Romantic novel: *Lucinde*, a celebration of a complete but extramarital love, notoriously based on his affair with his future wife, the divorcée Dorothea Veit (Moses Mendelssohn's daughter).

THE THEORY OF ROMANTIC POETRY

In *Athenäums-Fragment 116*, Schlegel's most influential account of Romantic poetry, he deems it "progressive universal poetry" because it aims not only to reunify all genres and connect poetry with philosophy but also to mingle and fuse "poetry and prose, genius and criticism, the poetry of the educated and the poetry of the people, to make poetry alive and social and to make life and society poetic, to poeticize wit, to fill and saturate the forms of art with matters of genuine cultural value" (*Athenäum I*, p. 220). To this end, a Romantic work is supposed to present sentimental but actual historical material in a witty, fantastic form ("an artfully ordered confusion") that is a synthesis of Eros and chaos, infinite unity and infinite fullness, mirroring nothing less than the universe

as a divine manifestation. The universe itself is conceived as a poem of the Godhead at this intersection of metaphysics and literary aesthetics.

In a good poem, as in reality, everything seems capricious and instinctive, though it is in fact necessary and deliberate. So, too, the Romantic artist must combine deadly seriousness with playfulness in a "constant self-parody," as Schlegel puts it. The model here is Socratic irony, a sense of the limitlessness of things and one's own limited capacity to express them, combined with the utter necessity of doing so.

In the final volume of *Athenäum* the emphasis on criticism and universality in the "Fragments" gives way to an enthusiasm for religion ("the all-animating world-soul of culture") and mythology (how "religion must appear in the world of language" (*Athenäum II*, p. 734, 740). In his "Ideas," which is deeply influenced by Schleiermacher, Schlegel touts the religious complementarity of poetry and philosophy that he also counterposes as realism and idealism, respectively. While claiming that "logic can develop into philosophy only through religion" and that "only someone who has his own religion can be an artist," Schlegel also insists paradoxically that "there is as yet no religion" (*Athenäum II*, p. 736, 751). Returning to this theme in "Dialogue on Poetry," he attributes the isolation of modern poets to their lack of a focal point such as ancient mythology provided ancient poets. He accordingly calls for the creation of a new mythology. This new mythology, like the ancient, would represent nature symbolically, though now against the background of philosophical idealism and the new physics (Schilling's philosophy of nature) and with an openness to the mythologies of the Orient.

THE LATER WORKS

After 1800 Schlegel's fortunes initially took a turn for the worse. He failed as a lecturer on transcendental philosophy at the University of Jena and as a playwright, his collaboration with his brother ended with the publication of *Characterizations and Criticisms* (1801), and his relationships to other members of the Romantic movement deteriorated. Isolated and financially strapped, Schlegel moved in 1802 to Paris, where he published the periodical *Europa*, in which he influentially opposed classicism again, this time by championing the symbolism of early modern religious painters. Vainly looking for a professorship, Schlegel moved to Cologne in 1804, where he helped rediscover German Gothic architecture and published *On the Language and Wisdom of India* (1808). Seminal for the development of Sanskrit studies, comparative linguistics,

and Indian philosophy, this work also contained attacks on pantheism that introduced Schlegel's final, Catholic phase of thinking.

Following his conversion to Catholicism, Schlegel moved to Vienna and worked for the Austrian government (serving as Prince Klemens von Metternich's representative at the Diet of Frankfurt) but also found time to give well-received lectures: *On Modern History* (published 1811) and the monumental *History of Ancient and Modern Literature* (published 1815). From 1820 to 1823 he published the periodical *Concordia*, to which he contributed "Signature of the Age," a plea for an "organic" state headed by a strong monarchy and animated by "corporations," most prominently, the Church. In lectures on the philosophy of life, history, and language in his final years (published from 1828 to 1830), Schlegel challenged reigning philosophical systems—deduced, in his view, from merely a part of human consciousness—with a "Christian philosophy" grounded in the total, personal experience of a thinker as a believer.

SCHLEIERMACHER, FRIEDRICH DANIEL ERNST (1768–1834)

Friedrich Daniel Ernst Schleiermacher was nineteenth-century Protestantism's great systematic theologian. It was he who marked the points of the compass for much of subsequent theology and philosophy of religion. Like St. Augustine, Schleiermacher desired to know God and the soul, and his place in the history of philosophy is due largely to the fact that he was able to state in modern language and concepts the great Augustinian conviction that religious faith is native to all human experience. Therefore, the knowledge of God and the knowledge of the soul are two orders of knowledge that must be distinguished but cannot be separated.

LIFE

Schleiermacher was first and foremost a preacher and theologian, a church statesman, and an educator. He carried out his work as a philosopher in the context of the great idealist systems of Friedrich von Schelling, Johann Gottlieb Fichte, and G. W. F. Hegel, but instead of attempting to imitate these men he applied himself to the critical analysis of religion, both in its personal and societal manifestations, without reducing such experience to some form of philosophic intuition. The upbringing that his father, a Reformed clergyman, gave him and his early education in Moravian institutions set Schleiermacher upon this course. After studying at the university in Halle and taking his examinations for ordination in 1790, he served briefly as a private tutor to the family of Count Dohna in East Prussia and as a minister in the Prussian town of Landsberg. In 1796 Schleiermacher settled in Berlin as a preacher, became a close friend of Friedrich von Schlegel, and emerged as an interpreter of religion to the romantic worldview that Schlegel himself epitomized. *On Religion: Speeches to Its Cultured Despisers* (1799) gave Schleiermacher a national reputation at the age of thirty. The following year another publication, *Soliloquies*,

attested to Schleiermacher's thorough absorption of the spirit of romanticism, but at the same time it indicated the direction that his ethical interests were to take in the future, as in his *Grundlinien einer Kritik der bisherigen Sittenlehre* (Outline of a critique of previous ethical theory; 1803).

The relation between the religious and ethical dimensions of life constituted a major preoccupation of Schleiermacher's maturity, and it is here that his indebtedness to and divergence from Immanuel Kant are clearly evident. Of decisive importance during his Berlin sojourn was his embarking upon the translation of Plato, in the course of which his mind became imbued with the philosophy of the author of the *Republic*. By 1804 Schleiermacher was teaching philosophical ethics (philosophy of culture), theology, New Testament, and hermeneutics at Halle. By 1810 he was lecturing as professor of theology at the University of Berlin, where for the remainder of his life he taught dogmatic theology, New Testament theology and criticism, hermeneutics, practical theology, history of philosophy, ethics, and dialectics, to name only the more important of the wide variety of subjects with which he dealt. Concomitantly he held an appointment as preacher at the Dreifaltigkeitskirche, to which he attracted persons from all sections of Berlin, and from this pulpit he wielded a powerful moral influence on the nation. In ecclesiastical politics he labored for the union of the Lutheran and Reformed churches in Prussia, and in national politics he worked not only for stiffer resistance to French expansionism under Napoleon Bonaparte but for internal social reform.

The Christian Faith (Der christliche Glaube nach den Grundsätzen der evangelischen Kirche im Zusammenhange dargestellt) appeared in 1821–1822 and in revised form in 1830–1831. Together with the *Brief Outline of the Study of Theology* (1st edition, 1811) and the two open letters concerning the revised edition of *The Christian Faith* which Schleiermacher wrote to a close friend (*Sendschreiben über seine Glaubenslehre an Dr. Lücke*, 1829), *The Christian Faith* gives us not only Schleiermacher's thought on Christian doctrine and substantive theological issues but also his conception of the organization of the theological disciplines and of systematic theology itself. Schleiermacher made Protestant theology methodologically self-conscious.

PHILOSOPHY OF CULTURE

Schleiermacher criticized Kant for tacitly making ethics into a "highest science" that ignored and devaluated the particular and idiosyncratic in human nature. Ethics,

Schleiermacher argued, is the discipline that has for its object "reason in history." Reason never appears except in historical personality—in the personalities of both individual persons and corporate persons. This position leads to a significant relaxation of the Kantian separation between practical reason, on the one hand, and the inclinations, temperament, talent, etc., on the other. Schleiermacher viewed these "accidents" and, indeed, the entire spatial, temporal embodiment of reason—apart from which we have no self-consciousness and hence no access to reason—not merely as the "place" of reason in its practical and theoretical functions but also as the organ of reason, by which reason itself is conditioned. The notion of a pure, universal reason could, therefore, be only a regulative concept for Schleiermacher.

Insofar as we consider reason in its practical capacity, as a willing or organizing activity, it is not the quest of virtue and autonomous assent to a self-imposed universal law that is foremost in view., but rather the sight of an ethical agent acting according to his own individuated rational nature. Moreover, the individuation of the ethical agent is accomplished not only by the "natural" accidents of time and place but also by the communities, societies, and institutions of which the individual person is the offspring. Schleiermacher presents the ethical agent as an end in himself, that is, as a good, who produces goods according to the peculiar law of his own unique nature. The doctrine of the highest good is formulated through the delineation of the relations of community and reciprocity in which such agents stand to each other, inheriting and endowing, receiving and bestowing. The primary forms in which these relations appear are the family, the nation, the church, the institutions of learning, and what Schleiermacher calls free sociality (*Geselligkeit*).

Nature and society affect reasoning in its theoretical as well as practical operations. When we think, we are conscious of engaging in an activity that is common to all men; nevertheless, our thinking, even at the most abstract level, as in thinking about thought itself, is in actuality predicated upon the specific organization of the physical means of sensation as well as upon the prior existence of a particular system of communication. The speculative activity of reason is thus conditioned by the natural medium in which it is individuated and shaped by the historical, moral character of the primary media (for example, a particular language) through which it maintains itself. Discourse is the means for the sociality of thinking, as Schleiermacher liked to say, and thinking is the inner side of speaking. He defined dialectic as the principles of correctly conducting a dialogue in the realm

of pure thinking and taught that all thinking proceeds in the form of dialogue or colloquy. On these grounds, Schleiermacher ruled out the possibility of an intuition of the absolute or of a highest science; the ideal and the real appear only as already informed by each other; pure spirit and matter lie outside of experience. Consequently, the ideal of a universal philosophy, for example, is nullified by the lack of a universal language and the impossibility of such.

The person, as the subject of the activities of thinking/knowing and of willing/doing, is more than a being composed of mind and body, individuated by time and space. A person not only is differentiated from others by nature and history but inwardly differentiates himself and acknowledges such an inward differentiation in all other human beings. That by virtue of which the person makes this inward differentiation is the *proprium* (*Eigen-thümlichkeit*). It is this property in each man that endows him with a life unity, an inalienable identity. Schleiermacher described this *proprium* as the peculiar organization that reason assumes for itself in each man. However, the life unity, or identity, of the individual person can never come to direct and full expression either in thinking/knowing or in willing/doing, although it accompanies and informs each of these rational activities. The self-consciousness that this sense of identity requires is a self-consciousness to be distinguished—though not isolated—from the forms of self-consciousness in which the subject is responding to or acting upon external objects.

Schleiermacher appropriates the word *feeling* for this form of self-consciousness, whose content is the given identity and unity of the self, incapable of being derived from others or surrendered to them. Feeling, thinking, and doing thus make up the three forms of consciousness that constitute the self-consciousness which distinguishes persons. Correspondingly, every person must be seen as a participant in the life of society in both his practical and theoretical functions, but he is also one whose *proprium* is wholly original. In a person whose feeling form of self-consciousness remains latent or inchoate, the sense of personal identity is deficient and personal consciousness is confused or immature. Such a person fails to contribute to the common or highest good; he is an inert reflection of his world, not one who moves and enriches it; he is a person in the formal sense but is destitute of spiritual life. Since, for Schleiermacher, religion is the most highly and fully developed mode of the feeling form of self-consciousness, all of human culture ultimately depends upon the cultivation of the religious life.

RELIGION

In his earliest published work, the *Speeches*, Schleiermacher made ample use of the romantic preoccupation with the nature and value of individuality, but he qualified the world view of German romanticism in two important respects. First, an individual comes to self-knowledge only in the presence of other persons; hence the need to know and to express the self can be fulfilled only by observing and cultivating the morality of human community and communication. Second, the individual's cultivation of his own humanity—which the romantic accepted as a self-evident imperative—requires that he acknowledge his religious nature, as well as his aesthetic, scientific, and moral nature, and that he cultivate this side of his nature, or self-consciousness, by seeking out religious community. Schleiermacher's thesis, from 1799 to his death, was that man is a religious being. But since the individual must always appropriate his humanity in a fashion that is at once concordant with his generic identity and accordant with his own peculiar identity, religion is as much a problem for the individual as it is a natural endowment. In his mature thinking, as he came to align himself theologically with Augustine and John Calvin, Schleiermacher stressed not only the fact that man is a religious being but also the fact that the most fundamental, pervasive confusion inhibiting human consciousness is religious confusion. Thus, in his Christian theology, he described sin as the failure to maintain a clear distinction between that upon which men are entirely dependent, God, and that upon which men are only relatively dependent, namely, objects within the world.

In *The Christian Faith*, Schleiermacher stated that religion is a determination of feeling. More narrowly defined, it is a feeling of being absolutely dependent, and this feeling, he believed, is one and the same thing with consciousness of being in relation with God. A number of elements in this characterization need to be distinguished if Schleiermacher is to be understood. (1) The feeling of being absolutely dependent is also the feeling of identity, through which the individual is conscious of his inner uniqueness; in describing this feeling as one of being absolutely dependent, Schleiermacher was calling attention to the fact that the identity, or life unity, of the individual is an endowment which cannot be derived from any of the intellectual or volitional relations in which the self stands to other persons and forces, taken either singly or together. In this sense, the individual is utterly dependent, for the particular constitution of his existence, on a "whence" that cannot be rendered conceptually. Hence, the feeling of absolute dependence is not expressive of a

felt deficiency or of awe, as it is according to the interpretation of Rudolf Otto in *The Idea of the Holy*; nor is it wholly the same as Paul Tillich's conception of faith as being ultimately concerned about that which concerns us ultimately, since this concern is aroused in part by what Tillich called "nonbeing." (2) The feeling of being absolutely dependent—or "immediate self-consciousness" or "God-consciousness"; Schleiermacher regarded all three terms as equivalent—is discernible only because self-consciousness also involves thinking and willing, which are forms of rational relation between the person and his world, forms involving consciousness of "relative dependence" and "relative freedom." The feeling of being absolutely dependent is distinguishable from the feeling of relative dependence by virtue of the fact that in the latter a person stands in the relations of community and reciprocity with nature and society, while in the feeling of absolute dependence there is no reciprocity present. Consequently, there can be no consciousness of being in relation to God, apart from consciousness of being in relation to the world. (3) The original meaning of the word *God* is not a concept of perfect being, or the like, but the felt relation of absolute dependence. Hence, religion arises not in ideas, nor—for that matter—in willing, but in the immediate consciousness of what Schleiermacher described to Lücke as "an immediate existence-relationship." (4) In fact, then, religion is more than a determination of feeling; it is the name Schleiermacher gives to the personal self-consciousness in which the feeling of absolute dependence and consciousness of the world coexist and must achieve or receive a living, stable order.

The religion that Schleiermacher described in this way is a purely formal and abstract religion, which exists nowhere in actuality. In conformity with the principles we have outlined above, he insisted that religion always appears in a particular social and historical form. The great religions are religions bearing the stamp of their founders, and he defined Christianity as a monotheistic faith of the teleological variety in which everything is related to the redemption accomplished by Jesus of Nazareth. Everything in the outward, social, and institutional aspect of Christianity is related to its founder, and similarly, everything pertaining to the inner piety of the Christian is related to the historical figure of the redeemer. Thus, while Christianity is, without question, the religion on the basis of which Schleiermacher formed his understanding of all other religions, what is of more importance is that he was the first among modern theologians to perceive that Christianity is historical in two senses. Not only does it have a history, but each Christian becomes a Christian by appropriating to his total self-

consciousness the relation to Jesus Christ. Christ must become a part of the self-consciousness, or inner history, of the Christian. There is no part of the relation to God, Schleiermacher stated, in which the relation to Christ is not also actively present. Hence, Schleiermacher revived in his conception of the feeling of being absolutely dependent the Augustinian notion of the inseparability of the knowledge of the soul and the knowledge of God; at the same time he originated the distinctive form of modern Protestant theology—Christocentrism, or Christ as the center of the individual's inner religious consciousness.

Bibliography

WORKS BY SCHLEIERMACHER

Collected Works and Letters

Aus Schleiermachers Leben in Briefen. 4 vols. Berlin, 1860–1863.

Sämtliche Werke. Berlin, 1835–1864. Published in three divisions: I, theological; II, sermons; III, philosophical and related subjects.

Schleiermachers Briefwechsel mit J. Chr. Gass. Berlin, 1852.

English Translations

Brief Outline of the Study of Theology. Translated by W. Farrer. Edinburgh, 1850.

The Christian Faith. Translated by H. R. Mackintosh and J. S. Stewart. Edinburgh, 1948; New York: Harper and Row, 1963.

Christmas Eve: A Dialogue on the Celebration of Christmas. Translated by W. Hastie. Edinburgh, 1890.

The Life of Schleiermacher as Unfolded in His Autobiography and Letters. 2 vols. Translated by F. Rowan. London, 1860.

"On the Discrepancy between the Sabellian and Athanasian Method of Representing the Doctrine of a Trinity in the Godhead." Translated by Moses Stuart. *Biblical Repository and Quarterly Observer* 6 (1835): 1–116.

On Religion: Speeches to Its Cultured Despisers. Translated by John Oman. London, 1893; New York, 1958.

Selected Sermons of Friedrich Schleiermacher. Translated by Mary F. Wilson. New York, n.d.

Soliloquies. Translated and edited by Horace Friess. Chicago, 1926.

Critical Editions

Der christliche Glaube, edited by Martin Redeker. 2 vols. Berlin, 1960. Contains appendices and Schleiermacher's own marginal notations.

Grundriss der philosophischen Ethik, edited by A. Twesten and F. M. Schiele. Leipzig, 1911.

- Hermeneutik, nach den Handschriften*, edited by Heinz Kimmerle. Heidelberg, 1959.
- Kurze Darstellung des theologischen Studiums*, edited by Heinrich Scholz. Hildesheim, 1961.
- Monologen*, edited by F. M. Schiele and Hermann Mulert. Leipzig, 1914.
- Reden über die Religion*, edited by G. C. B. Pünjer. Braunschweig, 1879.
- Schleiermachers Sendschreiben über seine Glaubenslehre an Lücke*, edited by Hermann Mulert. Giessen, 1908.
- Weihnachtsfeier*, edited by Hermann Mulert. Leipzig, 1908.

WORKS ON SCHLEIERMACHER

- Barth, Karl. *From Rousseau to Ritschl*. London: SCM Press, 1959. A sophisticated chapter on Schleiermacher by his foremost theological critic.
- Brandt, Richard. *The Philosophy of Friedrich Schleiermacher*. New York: Harper & Brothers, 1941. The most detailed examination of Schleiermacher's philosophy in English.
- Dilthey, Wilhelm. *Leben Schleiermachers*. Berlin, 1870; 2nd ed., edited by H. Mulert. Berlin, 1922. The classic biographical work on Schleiermacher, but extends only to the period at Halle. Should be supplemented by Dilthey's articles in his *Gesammelte Schriften*, 2nd ed. Stuttgart, 1959–1960. Vols. IV and XII.
- Niebuhr, Richard R. *Schleiermacher on Christ and Religion*. New York: Scribners, 1964. An account of the central ideas in Schleiermacher's theology against the background of his philosophy.
- Süskind, Hermann. *Der Einfluss Schellings auf die Entwicklung von Schleiermachers System*. Tübingen: Mohr, 1909. Valuable account of the early development of Schleiermacher's thinking.
- Wehrung, Georg. *Die Dialektik Schleiermachers*. Tübingen: Mohr, 1920. A scholarly examination of the development of Schleiermacher's lectures on this subject.

SCHLEIERMACHER, FRIEDRICH DANIEL ERNST [ADDENDUM]

In the past forty years there has been an explosion in research on Friedrich Daniel Ernst Schleiermacher in regard to both philosophical and theological dimensions of his thought. This entry is limited to discussing three issues of significance to philosophers: religious epistemology and the problem of religious pluralism, hermeneutics, and the question of the influence of Gottfried Wilhelm Leibniz, Immanuel Kant, and others on Schleiermacher's thought as a whole.

RELIGIOUS EPISTEMOLOGY AND RELIGIOUS PLURALISM

Schleiermacher's contribution to the question of religious pluralism lies in his religious epistemology, which is developed in the first twenty-two chapters of *The Christian Faith* (1821–1822, second edition 1830/1999) as well as in *On Religion* (1799/1996; other editions followed in 1806, 1821, and 1831). In both, he offers a comprehensive theory of the nature of religion grounding it in experience. In *On Religion* he grounds religion in an original unity of consciousness that precedes the subject-object dichotomy, and in *The Christian Faith* the feeling of absolute dependence is grounded in immediate self-consciousness.

In *The Christian Faith* Schleiermacher explains that doctrines are expressions of this fundamental experience: Christian doctrines are “accounts of the Christian religious affections set forth in speech” (p. 76, § 15). This view has been labeled *experiential expressivism*. Christian doctrines are not a set of truth claims that are to be judged in virtue of their correspondence with reality, but are rather a human attempt to express in symbols the experience of absolute dependence. This original experience is immediate and is not itself conceptually structured, for any conceptual structure presupposes the subject-object dichotomy and thereby also one's counter-influence on that which is posited. God cannot be “given as an object exposed to our counter-influence, however slight this may be” (1999, p. 18; §4.4). As such, theological concepts and symbols are only indirect representations of one's consciousness of God. Given such an understanding of Christian doctrines, it is possible that two religions with differing symbols both adequately express the feeling of absolute dependence. Nevertheless, while the feeling of absolute dependence is not itself conceptually structured, it determines the way that one represents and knows oneself and the world around one. Hence, Schleiermacher states that “the world will be a different thing to a man according as he apprehends it from the standpoint of a God-consciousness completely paralyzed or of one absolutely paramount” (p. 267; §64.2).

HERMENEUTICS

Schleiermacher's hermeneutics has also received a good deal of philosophical scrutiny. There are two diametrically opposed positions on the question of how it is possible to interpret a text or utterance. The first is the structuralist position: The meaning of any given utterance is determined by the publicly available meanings of the words that constitute it. Schleiermacher calls this the

“grammatical” element of language. According to the intentionalist position the meaning of an utterance lies in the intention of the speaker. The history and inner life of the speaker is of decisive importance in determining its significance. Schleiermacher’s hermeneutics, especially when understood in the context of his *Dialektik* (2001), offers a fruitful way to move beyond this impasse. According to Schleiermacher, one cannot strictly separate receptivity and spontaneity because both share a single underlying root. This plays a crucial role at several levels, the first being how one moves from sense-data to the ordinary world of tables and chairs. How the sense-data is organized will depend on the interpretive work of language: there is no bedrock given in receptivity. Ludwig Josef Johann Wittgenstein’s famous “duck-rabbit” is a useful example of this. Similarly, just as sense data provide no bedrock “given,” neither do the publicly available meanings of words. While language users begin from there, their own mental activity is important in shaping and sometimes even recasting those publicly available meanings. The level of the subject’s activity in shaping these meanings will vary from activity to activity, from high in aesthetic endeavors to low in scientific ones. For Schleiermacher, hermeneutics is “the art of understanding ... the ... discourse of another person correctly” (*Hermeneutics and Criticism*, p. 3). Both grammatical and psychological elements are vital to this task.

RECEPTION OF THE PHILOSOPHICAL TRADITION

Lastly, a good deal of scholarship explores the systematic character of Schleiermacher’s thought and how it relates to preceding philosophical thought. In what ways was Schleiermacher influenced by the systems of Plato, Leibniz, Spinoza, and Kant? For instance, Schleiermacher’s *Dialektik* has received a good deal of scrutiny. Several scholars point to Schleiermacher’s Leibnizian heritage and its relation to Schleiermacher’s reception of foundational Kantian ideas. Specifically, Schleiermacher’s adoption of Leibniz’s complete concept, which contains all the predicates applicable to an individual, does not square with another idea essential to Schleiermacher’s system, namely that one is both a spontaneous and receptive being. Schleiermacher agreed with Kant that what is given to one through sensation is necessary, although not sufficient for knowledge. But if this is true, all true judgments cannot be analytic, as the Leibnizian tradition assumed. There is an important class of judgments that are synthetic: they are true in virtue of some third thing that one becomes aware of through one’s receptivity.

SCHLICK, MORITZ (1882–1936)

Moritz Schlick, one of the founders of modern analytical philosophy and a guiding spirit of the Vienna circle of logical positivists, was born in Berlin. He was a direct descendant on his mother’s side of Ernst Moritz Arndt, the famous German patriot and political leader of the war of liberation against Napoleon Bonaparte. At the age of eighteen, Schlick entered the University of Berlin to study physics under Max Planck. He received his doctorate in 1904 with a dissertation on the reflection of light in a nonhomogeneous medium.

Schlick’s familiarity with the methods and criteria of research in the natural sciences left him dissatisfied with the epistemological notions both of neo-Kantianism, which then dominated the German universities, and of

Edmund Husserl's phenomenology, which had already become widely known. Instead, Schlick's starting point was the analyses carried out by Ernst Mach, Hermann von Helmholtz, and Henri Poincaré of the basic concepts and presuppositions of the individual sciences. His central interest at the time was the fundamental question of what is to be understood by knowledge.

From 1911 to 1917, Schlick served as lecturer and associate professor at the University of Rostock. In this period he published a series of works, among them his *Allgemeine Erkenntnislehre* (1918; 2nd ed., 1925). These works were devoted partly to a logically precise critical discussion of traditional philosophical conceptions and partly to an elaboration of new criteria for scientific knowledge which attracted considerable attention. In these publications Schlick already presented a first systematic account of his philosophical views.

In 1921 Schlick was named to a professorship at Kiel, and a year later he accepted a call to a chair in philosophy at the University of Vienna. These two years may thus be seen in retrospect as a kind of turning point in the history of philosophy. In 1921 Ludwig Wittgenstein had published his *Tractatus Logico-Philosophicus*, and in these same years the first writings of Rudolf Carnap appeared. Under the influence of Wittgenstein and Carnap, Schlick's philosophical views underwent a profound modification, which he later characterized by saying that he no longer saw the goal of philosophy as acquiring knowledge and presenting it as a system of propositions but, rather, as the application of a method. In applying its method, philosophy must take as its aim the discovery and understanding of the meaning of the statements, concepts, and formulations of problems of the special sciences, of philosophy, and of everyday life. When philosophy is understood in this manner, as Schlick emphasized in his French essay "L'école de Vienne et la philosophie traditionnelle" (*Travaux du IX^{ième} Congrès International de Philosophie*, Paris, 1937), it resembles the method of Socrates, who constantly strove in his conversations to clarify the concepts, assertions, traditional notions, and ordinary modes of expression found in both the philosophy and the practical life of his time.

Schlick taught at the University of Vienna from 1922 until his death in 1936. During these years he twice made trips to the United States as a visiting professor. While in Vienna, Schlick published *Fragen der Ethik* (*The Problems of Ethics*, 1930), as well as numerous papers, most of which were later collected in various volumes. But his views were disseminated most effectively, perhaps, through the discussion society that he founded and that

acquired a worldwide reputation as the *Wiener Kreis*. Besides professional philosophers, regular participants in the meetings of the Vienna circle included primarily mathematicians and natural scientists but also psychologists and sociologists. They published a profusion of writings of their own, in which they applied the methods—constantly refined in discussion—of the new Vienna philosophy to the fundamental problems of scientific research.

Schlick was responsible for Carnap's appointment as lecturer at the University of Vienna. Another member of the Vienna circle was Kurt Gödel, who in this period published his famous proofs of the completeness of first-order logic and of the incompleteness of formal arithmetic. Numerous scholars from Germany, Poland, England, Norway, Sweden, and the United States visited the sessions of the Vienna circle and took part in its discussions. Conflicting views frequently were championed, but the application of the most rigorous logical tools to the positions under consideration was common to all the deliberations. These discussions thus turned out to be a genuine symposium in the classical sense of the term, and the international exchange of views that took place worked a transformation in the philosophical thought of the American and European universities.

On June 22, 1936, while on the way to his lecture in the main building of the University of Vienna, Schlick was fatally wounded by a deranged student. The motives for this act have never been fully clarified. The assailant had been under psychiatric observation for some time because of a previous attempt on Schlick's life. With the death of Schlick, the meetings of the Vienna circle came to a sudden end. The Austrian Ministry of Education, for its part, now embarked on a reactionary cultural policy that barred representatives of scientific, analytic philosophy from all official chairs in the universities. With few exceptions, the participants in the Vienna circle immigrated to England and America. The rigorous scientific requirements of the Vienna philosophy met with widespread sympathy in the West and in Poland and Scandinavia; as a result, philosophy as the "logic of knowledge" experienced a fruitful further development abroad.

In Austria, however, the philosophical movement initiated by Schlick encountered the uncompromising hostility of the state authorities. After the interruption caused by World War II, all the official chairs in the Austrian universities were systematically filled by speculative philosophers generally committed to a theological outlook. Only exceptionally was a representative of scientific philosophy able to qualify as a lecturer. But since lectur-

ers and associate or titular professors, unlike regular professors, are not paid a salary in Austria, the authorities had an effective economic means of compelling the unwanted logical analysts of knowledge to turn elsewhere. In practice, this resulted in a suppression of scientific philosophy that continues to exist to this very day. The necessary consequence of a policy so harmful to science has been a shocking decline in the level of scholarship. Psychologically, the only explanation for this reactionary course of isolating research from the rigorous demands of modern scientific philosophy is the fear that logico-mathematical or empirical scientific analysis might endanger some ideological position. In support of this view is the fact that the eastern European countries, which profess a diametrically opposed ideology, also keep Viennese logical positivism away from their chairs of learning out of the same medieval anxiety that prevails in Austria.

CRITIQUE OF KANTIANISM

In his early work *Raum und Zeit in der gegenwärtigen Physik* (1917), Schlick presented a critical examination of the synthetic a priori character that Kantian transcendental philosophy attributed to propositions about space and time. Methodologically following the work of Poincaré and von Helmholtz, he based his thought primarily on the changes introduced by the theory of relativity into certain of the definitions and principles of classical physics. In conformity with scientific opinion of his time, Immanuel Kant had sought to establish the absolute validity of Newtonian mechanics by means of the theory of transcendental forms of intuition and of understanding. He regarded the presuppositions and basic principles of classical mechanics as necessary truths about empirical reality, that is, as synthetic a priori propositions. This conception had first been shaken by investigations of mathematicians. In consequence, doubt had also arisen regarding the synthetic a priori character of the general laws of physics. The theory of relativity made a final break with the synthetic a priori characterization of the foundations of Newtonian physics. According to relativity theory, statements about physical states (including propositions about physical space and physical time) are, as a consequence of the methods used by the natural sciences, empirical in character. That is, they are synthetic a posteriori propositions. Meanwhile, Poincaré had pointed to the possibility of interpreting general laws of nature, such as statements about physical space, as conventions or analytic propositions. Thus he had made evi-

dent the conventional nature of certain steps in the methodology of empirical research.

This systematic critique, confined at first to the foundations of mathematics and the natural sciences, was generalized by Schlick to all the basic problems of human knowledge. It thus became the basis of his philosophy in this initial period. In the *Allgemeine Erkenntnislehre* (1918), he made a critical study of all the propositions to which Kant and his followers had ascribed a synthetic a priori character. Schlick concluded that in all cases these propositions, where precisely formulated as logically necessary truths, are analytic in character; when, on the other hand, they are interpreted as statements with real content, they are empirical or synthetic a posteriori. There are no synthetic a priori propositions. Later, in his examination of foundational theories in logic and mathematics and of David Hilbert's formalism in particular, Schlick conceded that the possibility of synthetic a priori propositions in the realm of logico-mathematical forms must be left open. We are in no position to come to a final decision on this question. But even if necessarily valid propositions with content do exist—perhaps in the sense of the mathematical intuitionists—in the domain of logic and mathematics, they could never, Schlick stressed, be interpreted as absolutely valid statements about the empirically real world.

CRITICAL REALISM

Schlick's view was that epistemology, in investigating the criteria of reality, is not obliged in the first instance to ask for absolutely true knowledge of reality. The Cartesian method of doubt leads merely to immediate data of experience, the establishment of which in no way suffices to answer the question "What is real?" Instead of seeking absolutely certain knowledge, we must address ourselves to the systems of propositions by the aid of which science seeks to describe reality, and through a critical examination expunge from these systems all propositions that are demonstrably false. The system that remains will then portray reality just as it is. Here, when we speak of the reality depicted by the natural sciences, we mean those phenomena described by true spatiotemporal propositions. Schlick identified the objects of empirical knowledge, thus characterized, with the Kantian thing-in-itself; he called his own philosophical position "critical realism."

According to Schlick, the method by which we arrive at knowledge of the spatiotemporally ordered world has the feature that whereas the truth of propositions about objective, empirical reality can in principle be established only hypothetically, the falsity of such propositions can in

some cases be demonstrated beyond question. It is interesting to note that Karl Popper's asymmetrical confirmation theory, which did not appear until some twenty years later, likewise attributes a kind of certainty to the disconfirmation of natural laws in contrast with the fact that full verification is unattainable.

In this first period of his philosophical development, Schlick regarded the controversy between idealism and realism as a factual issue which philosophical reflection could resolve. He believed that critical realism provided the correct answer, and he sought to substantiate this answer by a more precise characterization of what is to be understood by empirical knowledge. Knowledge is "knowledge of sameness." Something is cognized as something else, for example, a whale as a mammal. An especially important form of the knowledge of sameness is recognition. Memory outputs over short spans of time are a constitutive element of consciousness. Knowledge of sameness includes not only establishing the sameness or similarity of sense data, memory images, imagined ideas, and the like but also the rediscovery of certain conceptual orderings known, say, from mathematics in the relationships of empirical phenomena. Schlick did not consider the possibility that the study of empirical relationships might lead to the construction of new, hitherto unknown mathematical orders and that in such a case one might arrive at knowledge descriptive of reality that is not knowledge of sameness.

LANGUAGE AND KNOWLEDGE

The problem of knowledge and its criteria had led Schlick to a further question: How is it possible to express knowledge linguistically? Scientific knowledge and insights, whether logico-mathematical or empirical, are presented in the form of sentences of some language. What conditions must be satisfied by these combinations of linguistic signs if they are to count as analytic or empirical sentences? In this earlier period Schlick's answer was the following: The languages employed in the sciences are designed to make possible the construction of unambiguous expressions that can be true or false. But this property of language presupposes the choice and establishment of rules according to which the linguistic signs are to be employed and to be strung out into expressions and sentences. If in using a language one does not heed the logical and linguistic rules set up for it, sign combinations will occur which, although they may appear on the surface to be sentences with a subject and a predicate, actually violate the rules for combining signs. Conse-

quently, they have no meaning and cannot be either true or false.

Applying this notion to philosophy, Schlick held that the theses of metaphysical systems are just such sequences of signs put together in a way that violates the logical rules of language. For this reason metaphysics is to be denied the status of scientific knowledge. But why does metaphysics disregard the logical rules of scientific languages in its linguistic formulations? Schlick thought the reason lay in the fact that whereas metaphysics endeavors to know reality, it does not seek to know the relations between the magnitudes characterizing states of affairs but strives to obtain knowledge of the content of phenomena. However, according to Schlick, only relations can be the object of knowledge—relations that reproduce the order of the phenomena and which include particulars on the number, sameness, similarity, and succession of the empirical data, as well as functional connections between measured quantities. The content of phenomena cannot be grasped by means of ordering relations, which are all that are at the disposal of the understanding. In Schlick's opinion, it is only through an intuitive, emotional experience that we can become acquainted with the actual content of reality. Metaphysics desires to know the "content" of real things, and it therefore finds itself compelled to use expressions from scientific languages in a manner contrary to the rules. For this reason the theses of metaphysics cannot have the character of meaningful propositions.

Schlick arrived at these views under the influence of the writings of Bertrand Russell and Hilbert, both of whom had by this time extensively treated the logical and linguistic foundations of mathematics. They clearly held that in mathematics questions about the logical and linguistic conditions for unambiguous statements must be put with special precision and exactness, but that these questions also affect the foundations of all scientific language systems and hence of scientific knowledge in general. Schlick was the first person to draw, on the basis of these insights into the foundations of logic and mathematics, consequences for epistemology as a whole and to undertake, by logical and linguistic means, the demarcation of a boundary between science and metaphysics.

PHILOSOPHY AND REALITY

During his teaching career in Vienna, Schlick subjected the philosophical views he had published before 1922 to a fundamental reexamination. Influenced by Wittgenstein and Carnap, he no longer saw the task of philosophy as the acquisition of knowledge. Instead, philosophy,

through the application of logical analysis to the concepts, propositions, and methods of the separate sciences, should aim at reaching an understanding of knowledge as found in the individual disciplines and of its presuppositions. Schlick no longer treated realism and idealism as factually contradictory theses but, rather, as alternative ways of speaking; at most, one could ask which permits a simpler, more easily understood way of talking about the world of experience and about purely conceptual relationships. But if realism and idealism are interpreted as statements about something that exists, the realism-idealism antithesis becomes a “pseudo problem” to which neither a true nor a false answer can be given.

This conception was carried over by Schlick to certain problems in the foundations of physics. In his essay “Die Kausalität in der gegenwärtigen Physik” (1931, reprinted in *Gesammelte Aufsätze* and in *Gesetz, Kausalität und Wahrscheinlichkeit*), he cited the answer given by Werner Heisenberg when he was asked to what extent particles are real or unreal. Heisenberg had replied that whether or not one wished to label particles as really existing was simply a matter of taste (*Die physikalischen Prinzipien der Quantentheorie*, Leipzig, 1930, p. 15). In the systems of propositions that constitute physics, we speak only about the data of observation and the regularities they display, or we construct hypotheses and predictions about the occurrence of observable phenomena. Whether the terms *real* and *unreal* are applied to the observational data, to the hypothetical constituents, or to any other elements of the theories is, so far as the content of the system of propositions is concerned, of no consequence at all. Descriptions in terms of “real” and “unreal” can be omitted without any loss of asserted content. Whether one wishes to make use of these terms is merely a matter of convenience and simplicity in expression.

PHILOSOPHICAL METHOD

Schlick generalized his analysis of modes of speech and ways of formulating questions into a philosophical method. Viewed from his new epistemological standpoint, numerous questions, especially in philosophy, turn out to be anchored in ordinary or scientific forms of speech, or in forms artificially created by metaphysics. The first step in Schlick’s method of analyzing knowledge consists in finding out the logical and linguistic rules governing the use of the expressions that occur in the problems, propositions, and forms of speech under study. Such a logical and syntactical critique may show that a certain expression, ordinarily assumed to have an unambiguous meaning, is being applied in accordance with dif-

ferent rules in different contexts and therefore is being used in different senses. A striking example is the concept of space. For a long time only one meaning was attributed to it, and the assumption was that the term *space* as employed in mathematics, physics, and psychology has the same meaning. The logical critique of language reveals that mathematical geometries represent analytic systems of relations, whereas physical space is described by means of a system of empirical laws that have as their content the order schema of possible positions and motions of physical bodies. Empirical sentences with different content describe the geometrical and metrical properties of psychological spaces—visual space, auditory space, tactile space, and the like. Similarly, in the case of such terms as *real*, *ideal*, *actual*, and *imaginary*, syntactical analysis yields different meanings corresponding to the different rules that govern the use of these expressions on various occasions. Failure to notice such differences of meaning often gives rise to philosophical problems which are then regarded as insoluble.

Thus the first step in the logical analysis of knowledge is to ascertain the rules for the linguistic use of the expressions under consideration. The second step is to study what meaning is to be ascribed to these expressions in a given complex of questions or system of propositions. Schlick called this the “interpretation” of the expressions, concepts, propositions, questions, or theories. If, for example, the first step in the analysis has shown that the word *real* is used in several senses, then the interpretation must determine which particular meaning the word has in, for instance, the sentence “Only that is real which is immediately experienced,” or in the sentence “The real is that which leaves traces behind,” or “The real is that which can be described by means of conjugate measured quantities.” The connection between the two steps in the method is manifest: The clarification of the possible meanings of an expression must precede the interpretation of it in a given context. According to Schlick, the understanding gained through interpretation is the insight for which philosophy strives.

Schlick applied his philosophical method, among other things, to the physical concepts of causality and energy and to the principles of causality and of the conservation of energy, which were still regarded as synthetic a priori propositions. Interpretation requires that in the case of “universally valid” sentences one must always ask whether one can conceive of conditions under which these sentences would have to be regarded as false. If they can be so regarded, then the empirical character of the sentences in question has been recognized. Schlick was

able to specify circumstances whose empirical confirmation is conceivable and under which both the principle of causality and the principle of the conservation of energy (as they are used within physics) would be termed invalid. Accordingly, he expressed the view—at a time when physicists were not yet of this opinion—that the two principles admitted of empirical testing. Subsequent research in physics has confirmed this view. At the same time, Schlick recognized that the concepts of causality and energy can also be defined in such a way that the principles of causality and of the conservation of energy become analytic sentences. It is this possibility that conventionalism exploits when it declares that general forms of laws are absolutely valid by convention. In a further application of his method, Schlick subjected Hans Driesch's vitalism and the general propositions both of psychology and of Husserl's phenomenology to an analytical critique. He arrived at the general conclusion that if the expressions these theories contain are precisely and properly clarified, the sentences in question take on either an analytic or an empirical character, but they never at one and the same time express synthetic and a priori propositions.

One criterion of meaning Schlick used in his analytical procedure was the criterion of verification that Schlick and others attributed to Wittgenstein. By this criterion, general laws of nature can have no significant content because they are not verifiable (or, as it is usually put, are not fully verifiable). This problem gave rise to wide-ranging discussions that went far beyond the Vienna circle. Essentially, Schlick supported Wittgenstein's view that natural laws are not themselves propositions but are to be understood as directives regarding the kind of sentences to be constructed in order to describe or predict individual cases of empirical phenomena. Directives cannot be true or false, so that on this interpretation the verification criterion is not applicable to the laws of nature. On several occasions Schlick characterized this interpretation of natural laws as not entirely satisfactory. But he did not find the opportunity for a definitive exposition of his own position.

PRESUPPOSITIONS AND CONFIRMATION PROCEDURES

Schlick replied to certain criticisms of the philosophy of the Vienna circle. Doubt was expressed that the criteria of the analysis of knowledge are sufficient for distinguishing between analytic and empirical sentences or for drawing a boundary between metaphysics and the individual sciences. Extreme skeptics even questioned the possibility of

making such sharp distinctions at all. One argument used by critics concerned the presuppositions that are required whenever one attempts to specify the conditions for determining unambiguously the meaning of concepts and propositions or for deciding unambiguously the truth of analytic and empirical sentences. These presuppositions evade any formal characterization or any determination of their validity, and consequently they have a metaphysical character. Even if these ineluctable presuppositions are limited to the minimal performances of memory necessary for recognizing in a subsequent moment what meaning we have previously assigned to a given expression, the knowledge by recollection we thus presuppose is intuitive in kind and as impossible to check as the theses of metaphysics. Because of these problematic presuppositions, the logical positivist distinctions between analytic and empirical propositions and between scientific and metaphysical propositions cannot possess any validity.

Schlick analyzed these criticisms of recollections that cannot be checked but yet must be presupposed if consciousness, language, thought, and knowledge are to exist. The real problem of the logic of knowledge, he argued, consists in the fact that despite the inexact presuppositions of our methods of knowledge, we nevertheless do obtain exact scientific knowledge. It is wrong to conclude that because the recollections presupposed are unanalyzable and intuitive, the formal logico-mathematical derivations, concept formations, and principles or the empirical criteria of meaning and judgment are inaccurate. The exactness of scientific methods is anchored in proof procedures that guarantee an undeniable advance of knowledge in all the sciences. These procedures distinguish exact scientific knowledge from unverifiable metaphysical speculation. There are no such confirmation procedures for metaphysics, nor does it permit the application of scientific (logical or empirical) criteria of confirmation to its theses and methods. Consequently, in metaphysics there is no such thing as progress of knowledge. Thus the decisive criterion of exactness for the sciences is the advance in knowledge that can be gained through the process of testing, a criterion not satisfied by the speculative methods of metaphysics.

ETHICS AND VALUE THEORY

Schlick also applied the method of the analysis of knowledge to problems of ethics and the theory of value. He concluded that the a priori arguments for absolute values do not fulfill the logical criteria of meaning. Only the value-ascribing forms of behavior actually found among

people, relative assignments of relative values, can be taken as the basis for ethical and other value systems. In Schlick's view, this sort of value analysis leads to a new kind of empirical foundation for eudaemonism. In his *Fragen der Ethik*, Schlick offered as the fundamental principle of an ethics so based the maxim "Increase your happiness" (*Mehre deine Glückseligkeit*).

Schlick's ethics has been widely criticized as superficial, on the ground that there can be morally objectionable happiness. To understand it correctly, one must take into account how he characterized the happiness that one should strive to increase. By happiness he meant the quiet, joyous assent that accompanies our actions when we carry out for its own sake some activity springing from our talents. This is the kind of activity that is to be evaluated as ethically worthwhile behavior. The joy in such activity resembles the joy of a child at play, and it should be regarded generally as the criterion for emotional and intellectual youthfulness. This youthfulness is not tied to physical age. Anyone who has found the activity proper to himself, and has thus experienced this quiet, joyous happiness, has realized the highest attainable ethical goal and will keep his youthfulness throughout his entire life. On this basis, Schlick rejected all varieties of ethical rigorism, including the Kantian system. No ethical worth can be attributed to actions undertaken from a mere sense of duty when such actions inspire only distaste and annoyance both beforehand and afterward. On the contrary, acting out of a sense of duty is ethically valuable only if a quiet satisfaction accompanies the action. Moral value, Schlick used to emphasize, attaches only to vital action; the sign of life is youthfulness, but we are young only when we act from joy. When the quiet, inner joyous assent accompanies our action, we fulfill the requirements of the highest principles of ethical value.

SCHOLZ, HEINRICH

(1884–1956)

Heinrich Scholz, the German theologian and logician, was born in Berlin. He professed an outspoken Platonism based on a profound knowledge of the history of metaphysics and of the logical works of Gottfried Wilhelm Leibniz, Bernard Bolzano, and Gottlob Frege. Scholz identified philosophy, in its original Platonic sense as the striving for universal knowledge, with the study of the foundations of mathematics and science. Thus, in *Was ist Philosophie?* (1940; *Mathesis Universalis*, pp. 341–387) he concluded, from Plato’s demand for knowledge of geometry and a mathematical astronomy, that the axiomatic method is required for universal knowledge. He regarded mathematical logic as developed by Leibniz, Bolzano, Frege, Bertrand Russell, and others as the “*epochale Gestalt*” of *metaphysica generalis*. He opposed formalism in logic because it failed to provide for the semantics of formal languages, and he opposed constructivism because of its arbitrary anthropocentric limitations of logic.

Scholz’s devotion to logic arose from a concern with metaphysics in theology. He studied theology at Berlin and philosophy at Erlangen, receiving a doctorate in philosophy from Erlangen with a dissertation on Friedrich Schleiermacher. He held the chair of systematic theology and philosophy of religion at Breslau from 1917 to 1919,

and then a chair of philosophy at Kiel. In his main systematic theological work, *Religionsphilosophie* (Berlin, 1921), he rejected subjective and existential foundations for religion. God is a transsubjective datum whose being is independent of any “leap of faith”; otherwise truth would be irrelevant to religion: “nothing remains but either to give up the solution to the problem of truth or to enter upon an entirely new course” (*Mathesis Universalis*, p. 13). By a “lucky accident,” the discovery of A. N. Whitehead and Russell’s *Principia Mathematica* in the library at Kiel, Scholz found his new course. From 1923 to 1928 he immersed himself in the study of logic, mathematics, and physics, and of their histories. His thoughts on metaphysics were galvanized, and he developed an enthusiasm for logical calculi rare even among mathematicians; it infused his later lectures and doubtless alienated those readers in Germany who were not quite convinced of the need to analyze Plato and other classical metaphysicians logically.

In 1929, his metamorphosis into a logician complete, Scholz assumed a chair of philosophy at Münster, which was transferred to the mathematical faculty in 1943 when he founded the Institut für mathematische Logik und Grundlagenforschung. This institute was inspired by the Warsaw school under Jan Łukasiewicz (whom Scholz later rescued from a Nazi concentration camp). But Scholz did not renounce theology. In “Das theologische Element im Beruf des logistischen Logikers” (1935; *Mathesis Universalis*, pp. 324–340) he likened his motives for undertaking *Grundlagenforschung* to the motives of an Augustinian theologian in search of illumination from the eternal forms. He undertook logical investigations of Anselm’s ontological argument (“Der Anselmische Gottesbeweis,” 1950; *Mathesis Universalis*, pp. 62–74) and of Augustine’s arithmetical proof (“Der Gottesgedanke in der Mathematik,” 1950; *Mathesis Universalis*, pp. 293–312).

Scholz wrote one of the first competent histories of logic, *Abriss der Geschichte der Logik* (Berlin, 1921; translated by Kurt F. Leidecker as *Concise History of Logic*, New York, 1961), based on the pioneering studies of Louis Couturat and Łukasiewicz. He exhibited what may be called a coincidence of logic and metaphysics through several works that together constitute in effect the first logically competent history of metaphysics. His “Logik, Grammatik, Metaphysik” (1944; *Mathesis Universalis*, pp. 399–438) discusses metaphysics in Aristotle, Leibniz, and Immanuel Kant. “Die mathematische Logik und die Metaphysik” (*Philosophisches Jahrbuch der Görres-Gesellschaft* 51 [1938]: 257–291), a 1938 lecture intended to convince a meeting of German Thomists of the impor-

tance of mathematical logic, discusses scholastic philosophy, Plato, and Aristotle. He discusses the fundamental importance of the axiomatic method for metaphysics in “Die Axiomatik der Alten” (1930; *Mathesis Universalis*, pp. 27–44), on Aristotle’s *Posterior Analytics*; in *Was ist Philosophie?*; and in *Die Wissenschaftslehre Bolzanos* (1937; *Mathesis Universalis*, pp. 219–267). Scholz regarded the *mathesis universalis* of René Descartes, Blaise Pascal, and Leibniz as of special importance in the history of metaphysics. He developed Leibniz’s metaphysical doctrines of identity and possibility in *Metaphysik als strenge Wissenschaft* (Cologne, 1941), a thorough treatment of the logic of identity, and in *Grundzüge der mathematischen Logik*, written in collaboration with Gisbert Hasenjaeger (Göttingen, 1961). In *Grundzüge*, logical truth is defined as that which is identical throughout all possible worlds. Scholz used this definition to explain the a priori (the pre-Kantian *Transzendente*): Possible (not necessarily actual) worlds constitute the logical frame for any description of the real world. Scholz’s “Einführung in die Kantische Philosophie,” a series of lectures given in 1943 and 1944 (*Mathesis Universalis*, pp. 152–218), was the first systematic treatment of Kant’s logical, mathematical, and physical doctrines to call upon both mathematical logic and physics. Of particular interest is Scholz’s account of how Kant came to reject the *mathesis universalis* because of Christian Wolff’s garbled presentation of Leibniz’s mathematical philosophy.

Scholz greatly admired the work of the Vienna circle, particularly that of Rudolf Carnap. However, he held that Platonism, especially in the form of classical mathematics, has been more useful to science than positivism, since it permits theoretical constructions more powerful than any offered by positivism. Positivism retards scientific growth. Thus, according to Scholz, modern relativity theory, even though positivistic tendencies helped lay its observational foundation, is Platonist because of its use of classical analysis. According to Scholz, the logic of Frege and Russell was adequate evidence that Platonism is feasible, and Alfred Tarski’s noneffective method of proof and his semantic definition of truth proved that Platonism can be given an absolutely rigorous foundation.

Scholz held that competence in metaphysics requires knowledge of mathematical logic, but he failed to convince most German metaphysicians. His works were ignored, and irrationalism exercised virtual hegemony in Germany during the Nazi era. (Even in the United States, his work was mentioned only in the *Journal of Symbolic Logic*.) Scholz saw language being employed as a poorly controlled, quasi-literary means of expression rather than

as a logical tool for grasping objective truth. He therefore engrossed himself in his technical work, the crowning achievement of which was the posthumously published *Grundzüge der mathematischen Logik*. This work deals extensively with the elements of logic; develops propositional logic, quantificational logic, and type-theoretical logic (this last is called “Russell-revised Platonism” because it functions as an ontological foundation for mathematics) in formalized syntactic and semantic metalanguages; and examines the questions of completeness and independence with respect to both effective and non-effective proof methods.

Eckehart Köhler (1967)

SCHOOL OF QOM, THE

The School of Qom refers to the tradition of theological institutions of Shi‘a learning in Qom, a city in southern Iran. Along with Meshhad in North Eastern Iran and Karbala and Najaf in Iraq, Qom is a major center of Shi‘ism, which houses the golden domed shrine of Fatimah, the holy site named for the sister of the eighth Imam who died in 816 in Qom and was buried there. Recently a few speculative theologians of this school proffered the theoretical foundation for a theocracy commonly labeled as an “Islamic Republic”; their views have become a cause célèbre in the Muslim world in a challenge of and a confrontation with the European cultural, economic, and

political dominance in many predominately Muslim states. In spite of its political charisma, Qom continues to be the source of research in the scholarship of the Shi‘a philosophical heritage and exports a number of both young and seasoned scholars to the most prestigious European academic centers.

BACKGROUND

(a) Following the teachings of Nāṣir Khosrow (b. 1003–4) and Nāṣir al-Dīn al-Ṭūsī (1201–1274), traditional curricula of the school of Qom and its approach to Islamic studies integrate religious studies with philosophy and mysticism.

(b) In their ethics of self-realization and in their social philosophy, members of the school of Qom focus on philosophies of intentional processes and on analyses of mystical virtues (instead of “the golden mean”); they praise the use of archetypal memory (*dhikr*) and empathetic intimacy (*uns*) with the ultimate being. A key explicit view is the rejection of the Aristotelian depiction of time as an accident and the replacement of substance-event metaphysics with the so-called “process” ontology, expressed in Mullā Ṣadrā’s so-called theory of “substantial motion.”

(c) Members of the Qom school are actively engaged in an encounter with Europe; they do appreciate the development of European science as a continuation of Islamic sciences, and have mastered the art of application of computer technology to the humanities, such as the scanning of basic Shi‘a literature and internet communications.

MAJOR FIGURES AND CONTRIBUTIONS

A majority of Iranian theologians were educated and taught in Qom. Salient doctrines of four major thinkers of this school follow:

HUSSEIN TABATABA’I (1903–1981). The most prominent thinker of this school is ‘Allameh Seyyed Muhammad Hussein Tabataba’i (hereafter “Tabataba’i”), a scholar of Shi‘a theology and teacher of recent major thinkers of the school of Qom. Although not directly involved in politics, his writings established the school’s theocratic agenda with key political implications.

A major aim of human actions is happiness, according to Tabataba’i—a desire that is only partially achievable in societal contexts that are regulated by laws that focus on external interrelations among human beings. Religious beliefs connecting the internal, intentional, and

spiritual bases of persons to the cosmos create an intimacy with the creator that complements the deficiencies of secular laws by providing total fulfillment of persons' needs, balancing tolerance with praxis. According to Tabataba'i, Islamic society goes beyond tolerance in recognizing the religious practices of other peoples of the book (Jews, Christians, and Zoroastrians) who live under the rule of an Islamic state and contribute to it through their taxes. However, the Muslim community is committed to jihad against those who knowingly reject the principle of unity, namely against rebellious Muslims, against enemies of the faith, and against those who transgress against Islam by occupying the Muslim homeland by force. Following Islamic traditional belief, Tabataba'i considers homicide a major sin against all humanity. For pragmatic purposes, truth may be hidden (the principle of *taqiyya*) when the expression of truth endangers the cause of religion. While speculation about religion is normally not recommended, Islam is open to new visions, inviting learned scholars to make innovations (*ijtihad*) in deducing philosophical points from archetypal monotheistic truths.

MURTTAZA MUTAHHARI (1920–1979). Mutahhari's major achievement was the dissemination of a clear, rational justification of the political views of the school of Qom to the Iranian Shi'a masses, as his books were printed by the tens of thousands and circulated as textbooks in many schools. Although Mutahhari is known primarily for his plan to refute communism, no less well known is his open acceptance of the advancement of European science and his caricature of the claim of supremacy of European secular philosophy. His research focuses on a number of politically important reforms. For example, he criticized the literal interpretation of sacred texts and advocated the rational adoption of religious archetypes to solve contemporary problems; he advocated the education of women; and he was receptive to the progress of science and technology. Significantly, he preferred political action as a specific innovative application of religious precepts carried out under the guidance of an exemplary political leader, and he eternalized the ethos of the martyrdom of Karbala, and in so doing providing an energizing rationale for the Islamic revolution.

ROHALLAH KHOMEINI (1902–1989). More than any member of this school, Khomeini permanently influenced the course of history of the Islamic world, claiming execution of basic Islamic principles such as Prophet Muhammad's agenda in the transformation of persons

from a tribal self to a member of a community of the faithful. In this tenor, a salient feature of Khomeini's political theory was his emphasis on how persons need to feel an intimate existential allegiance to Islam's spiritual nature in order to experience their religious societal self. The faithful are guided by the juridical authority in their participation in a revolution that has the following agenda: (a) to create a continuous confrontation with secular nationalism; (b) to challenge European secular capitalistic political and military imperialism that supports European puppet regimes in predominately Muslim countries; (c) to issue directives against the lives of those who transgress against Islam in any place in the world; and (d) to constitute—in the absence of an Imam (spirited leader)—a juridical authority that supercedes the authority of monarchs or even that of the elected president of a country.

PRESENT STATUS

Qom remains the major center of academic Shi'a research, where, in addition to Islamic studies, both male and female students study the works of philosophers such as Bertrand Russell, Ludwig Wittgenstein, and Martin Heidegger, and where mastery of computer technology applications to the humanities is expected of students.

Parviz Morewedge (2005)

SCHOPENHAUER, ARTHUR (1788–1860)

Arthur Schopenhauer was a German philosopher of pessimism who gave the will a leading place in his meta-

physics. He was born in Danzig. His father, a successful businessman of partly Dutch ancestry, was an admirer of Voltaire and was imbued with a keen dislike of absolutist governments. When Danzig surrendered to the Prussians in 1793, the family moved to Hamburg and remained there until the father's death (apparently by suicide) in 1805. Schopenhauer's mother was a novelist who in later years established a salon in Weimar, which brought him into contact with a number of literary figures, including Johann Wolfgang von Goethe. His relations with his mother, however, were bitter and antagonistic and eventually led to a more or less complete estrangement.

EDUCATION

Schopenhauer's early education was somewhat unconventional. He spent two years in France in the charge of a friend of his father, and for another period he accompanied his parents on a prolonged tour of France, England (where he attended school in London for several months), Switzerland, and Austria. After his father's death he was tutored privately in the classics for a time and then entered the University of Göttingen as a medical student, studying, among other subjects, physics, chemistry, and botany. At Göttingen he first read Plato and Immanuel Kant, and the powerful and lasting impression their writings made upon him directed his interests decisively toward philosophy. In consequence he left Göttingen in 1811 for Berlin, which was at that time the chief philosophical center in Germany, and worked there for two years, attending the lectures of Johann Gottlieb Fichte and Friedrich Schleiermacher (both of whom he found profoundly disappointing) and making preparatory notes for a doctoral thesis. When the uprising against Napoleon Bonaparte led to the closing of the university, Schopenhauer, for whom nationalistic sentiment held little appeal, retired to Rudolstadt to write his thesis, subsequently published there in 1813 under the title of *Über die vierfache Wurzel des Satzes vom zureichenden Grunde* (*On the Fourfold Root of the Principle of Sufficient Reason*).

EARLY CAREER

Apart from producing a short book on the perception of color, *Über das Sehn und die Farben* (Leipzig, 1816), which was inspired by a previous essay on the same subject by Goethe, Schopenhauer employed the next four years writing his principal work, *Die Welt als Wille und Vorstellung* (*The World as Will and Idea*). From the very first stages of the composition of this work, Schopenhauer believed that the ideas he was striving to express were of major importance, and when it was published at

Leipzig in 1818 (dated 1819), he was confident that its significance would immediately be recognized. In this expectation he was to be quickly disappointed; the scanty reviews his book received were generally tepid in tone, and the number of copies sold was small. Nevertheless, its publication helped him to obtain the post of lecturer at the University of Berlin, where he chose to give lectures at the same hours as G. W. F. Hegel, who was then at the height of his reputation and popularity. From the start, Schopenhauer advertised his opposition to Hegelian conceptions. He spoke of sophists who, having arisen after Kant, "first exhausted the thinking power of their time with barbarous and mysterious speech, then scared it away from philosophy and brought the study into discredit," and he made it clear that he regarded his own mission as one of repairing the damage that had been done. Schopenhauer's lectures, however, were a failure; Hegel's authority was too firmly established to be undermined in this manner, and Schopenhauer's audience dwindled away.

LATER CAREER

Schopenhauer made no further attempt to establish himself academically. From then on he lived a solitary life, profoundly resentful at the lack of the recognition he felt to be his due and confirmed in his opinion that the dominant Hegelian philosophy was the product of a charlatan who, by an artful combination of sophistry and rhetoric, had succeeded in corrupting the intellects of an entire generation. Despite his disappointment, however, Schopenhauer continued to write, producing books that were in effect elaborations and developments of themes already adumbrated in his main work. He published an essay titled *Über den Willen in der Natur* (Frankfurt, 1836); and a volume on ethics and the problem of free will, *Die beiden Grundprobleme der Ethik* (Frankfurt, 1841), which contained the two essays "Über die Freiheit des Willens" (1839) and "Über die Grundlage der Moral" (1840). In 1844 he brought out a second edition of *Die Welt als Wille und Vorstellung*, greatly expanded by the addition of fifty supplementary chapters. He also contemplated translating Kant's *Critique of Pure Reason* into English and David Hume's *Dialogues concerning Natural Religion* (a work he greatly admired) into German. There can be little doubt that he would have performed both of these tasks well, for his knowledge of English was excellent; but unfortunately nothing came of either project. Finally, Schopenhauer published a collection of essays and aphorisms called *Parerga und Paralipomena* (2 vols., Berlin, 1851), and with this work he began to be widely

known. Discussions of his ideas appeared in foreign as well as in German periodicals, and his system was made the subject of lectures in a number of major European universities. By the time of his death in Frankfurt, he had a growing circle of admirers in England, Russia, and the United States, while nearer home the influence of his writings was soon to show itself in the work of such thinkers as Friedrich Nietzsche and Jakob Burckhardt.

CHARACTER

Schopenhauer's personality, which is reflected in much of his writing, was complex and compounded of curiously diverse elements. Although intellectually self-assured to the point of arrogance, he had a brooding, introspective disposition, and he betrayed an extreme susceptibility to irrational fears and anxieties. Thus, he always slept with a loaded pistol near him, and he took compulsive precautions against disease; he once remarked that if nothing alarmed him, he grew alarmed at this very condition—"as if there must still be something of which I am only ignorant for a time." His manner could be truculent and overbearing; as many of his aphorisms make clear, his view of others was colored by a deep suspiciousness and cynicism, and his general outlook on life and existence was unrelievedly pessimistic. Yet this did not prevent him from taking pleasure in many things—art and music, good food and wine, travel, and, despite his notorious essay on the subject, women. And while he detested bores, in company that he found sympathetic he appears to have been a lively and entertaining talker, displaying a sharp, satirical wit.

THE NATURE OF PHILOSOPHICAL THINKING

Schopenhauer's philosophy is best approached from a position that clearly recognizes his indebtedness to Kant, whom he believed to have been indisputably the greatest thinker of modern times. Schopenhauer's chief charge against his own philosophical contemporaries in Germany (Friedrich von Schelling, Fichte, and Hegel)—was that under the pretense of carrying forward and developing Kantian ideas, they had in fact attempted to philosophize in a fashion that Kant himself had ruled out as wholly inadmissible. For if Kant had shown anything, it was that metaphysical speculation in the old "transcendent" sense was useless as a means of achieving knowledge of what lay beyond all human experience. Such knowledge is in principle unattainable, and it followed that any philosopher, whatever his procedure might be, who tried to establish such things as the existence of God

and the immortality of the soul was engaged in a hopeless quest.

Rationalist metaphysicians like René Descartes had employed deductive a priori arguments in an endeavor to prove certain fundamental propositions of theology, and Kant had sufficiently exposed the inadequacy of these arguments by a series of devastating refutations. Yet according to Schopenhauer, Kant's strictures had not prevented some of his self-appointed successors from speaking as if they had mysterious access to truths necessarily outside the range of human cognition—a "little window opening on to the supernatural world," as it were. He suggested, too, that writing in this way appeared more expedient to many academic teachers of philosophy than the honest alternative of expounding truthfully and directly the antidogmatic theses contained in the *Critique of Pure Reason*.

While he accepted Kant's reasons for rejecting metaphysical theorizing in the sense described above, Schopenhauer was nevertheless far from wishing to claim that all philosophical speculation concerning the ultimate nature of the world must be deemed illicit and misconceived. The impulse to seek some general interpretation of reality and of the place of human existence within it was too deeply embedded in the human mind to be totally ignored or set aside. Man, Schopenhauer held, is an *animal metaphysicum*, a creature who cannot avoid wondering at the existence of the world and raising questions concerning its fundamental character and significance—questions that empirical science is unable adequately to resolve, for they lie beyond its sphere. Religion, it is true, attempts in its own way to meet this pervasive need, although not in a manner susceptible to rational justification or certification. For the tenets and concepts of religious faiths, whatever those who subscribe to them may believe to the contrary, can never be more than "allegories" or imaginative figures, and treating them as if they represented literal truths about a higher order of things leads straightway to manifest absurdities and contradictions.

By contrast, the concern of philosophical thinking is not with the metaphorical intimation of ideas that are beyond the grasp of the human intellect; rather, such thinking aims at truth *sensu proprio*. It follows, therefore, that any solution of "the riddle of the world" that philosophy purports to provide must not be one that involves overstepping the boundaries within which all human knowledge is set and confined. The determination of exactly where these boundaries lie is accordingly of pri-

mary importance as a preliminary to all philosophical inquiry.

PERCEPTION AND THOUGHT

Schopenhauer's theory of knowledge may be said to start with Kant's distinction between *phenomena* (what appears to a perceiving mind) and *noumena* (things as they are in themselves). In our perceptual consciousness of the world, we are in fact aware of it only as mediated through our sense organs and intellect—a point Schopenhauer expressed by saying that, so conceived, the world is “idea” or “representation” (*Vorstellung*). Moreover, everything that presents itself to us in perception necessarily conforms to a certain formal and categorical framework that underlies and finds expression in all departments of our commonsense and scientific knowledge.

Thus Schopenhauer was at one with Kant in holding that the human mind cannot (as the British empiricists had suggested) be envisaged as a mere passive recipient of sense impressions, but on the contrary plays an essentially active part in shaping and organizing the sensory material. It is the structure of the intellect, comprising “sensitivity” and “understanding,” which ensures that this sensory material apprises us of a realm of external objective phenomena, spatially and temporally ordered and standing in determinate causal relations both with one another and with ourselves as percipients. Space and time as forms of sensibility, together with causality considered as the sole category of the understanding (here Schopenhauer diverged from Kant), are therefore “subjective in origin,” while at the same time they are necessary conditions of our knowledge of the world as idea. According to Schopenhauer, it is also the case that their valid employment is restricted to this sphere; they have no application to anything not given, or that could not be given, in sense experience.

Schopenhauer distinguished a further class of ideas, namely, what he termed “ideas of Reflection,” or sometimes “ideas of ideas” (*Vorstellungen von Vorstellungen*). It is in terms of these that we think about and communicate the contents of our phenomenal experience. In other words, they are the general concepts by virtue of which we can classify phenomena according to common features that are of interest or importance to us, forming thereby a conceptual structure or system that may be said to mirror or copy the empirical world. The function of this system is essentially a practical one; it provides a means of memorizing, and generalizing from, our observations of how things behave under varying conditions,

and hence of putting to use what we learn from experience.

Schopenhauer insisted, moreover, that this system cannot legitimately be separated from the foundation of empirical reality upon which it is based, and he claimed that concepts and abstract notions that cannot be traced back to experience are comparable to bank notes “issued by a firm which has nothing but other paper obligations to back it with.” Consequently, metaphysical theories that pretend to offer an account of the world purely a priori, and that in doing so employ terms or propositions not susceptible to empirical interpretation, are empty of cognitive content; they “move in the air without support.” Indeed, such theories often represent no more than the development, by laborious deductive steps, of the implications of a small group of initial axioms or definitions, yielding systems of empty tautologies.

Thus far, Schopenhauer would appear to have placed fairly stringent limits upon the scope of human inquiry. Attempts to transcend these limits by appealing to the resources of deductive reasoning alone are necessarily impossible, since they involve fundamentally wrong ideas concerning the nature of logical inference. These ideas can never provide us with information of which we were not previously cognizant, for such inference merely makes explicit what is already implicitly asserted in the premises from which it proceeds. Equally, there can be no justification for trying to extend the use of nonlogical, formative principles like the principle of causality in order to establish matters of nonempirical fact, after the manner of some earlier metaphysicians. Schopenhauer even accused Kant of inconsistency in this matter, on the ground that he wrote as though the existence of things-in-themselves, which for Kant are by definition incapable of being experienced, could be validly inferred from the phenomenal data, thereby disregarding his own prohibition. Nonetheless, Schopenhauer considered that the Kantian notion of the thing-in-itself remained a fertile one. Properly conceived, it offered the needed clue to the discovery of a legitimate and correct philosophical interpretation of existence.

THE WILL

According to Schopenhauer, it is not true that the thing-in-itself, the noumenal reality that underlies the world of phenomenal appearances, is beyond the range of all possible human experience. To realize this, it is necessary to take account of the facts of self-consciousness, that is, our own intimate knowledge of ourselves. Self-awareness has two distinct aspects. From one point of view, namely, the

standpoint of ordinary perception, I cannot avoid regarding myself as an “object,” as much a physical entity as a building or a tree is. In this sense, I necessarily conform to the conditions that constitute the “world as idea” in general; I am a body that occupies space, endures through time, and causally responds to stimuli.

INDIVIDUAL WILL. My inner experience also assures me that I am nevertheless more than “an object among objects,” for I do not appear to myself under this aspect alone. I am also aware of myself from within as a self-moving, active being whose overt perceptible behavior directly expresses my will. This inner consciousness that each one of us has of himself as will is primitive and irreducible. Thus, Schopenhauer claimed that the will reveals itself immediately to everyone as the “in-itself” of his own phenomenal being and that the awareness we have of ourselves as will is quite different from the awareness we have of ourselves as body. At the same time, however, he emphatically denied that the operations of a man’s will and the movements he makes with his body are two distinct series of events—events of the first kind being thought of as causally productive of events of the second kind. Schopenhauer believed that dualistic conceptions of the relation of will and body, deriving largely from Descartes, had wrought havoc in philosophy, and he argued instead that a man’s body is simply the “objectification” of his will as it appears under the conditions of external perception; what I will and what in physical terms I do are one and the same thing, but viewed from different standpoints.

THE WILL IN NATURE. What has just been discussed represents the cornerstone of Schopenhauer’s metaphysic. For it was his contention that we should not assume the above distinction between the phenomenal appearance and the thing as it is in itself to apply only insofar as we ourselves are concerned. On the contrary, just as my own phenomenal being and activity is ultimately intelligible as the expression of my inner will, so may the rest of the phenomenal world be understood to share the same fundamental character that we recognize to be ours. Here was the “great extension” of the concept of will whereby Schopenhauer claimed that all phenomena—human and nonhuman, animate and inanimate—might be interpreted in a way that gave the world as a whole a new dimension of significance and that at the same time was not open to the insuperable objections vitiating traditional metaphysical doctrines.

The latter claim may reasonably be doubted. Schopenhauer often displayed considerable perspicacity

in detecting errors and inconsistencies in the theories of other philosophers, but he did not always show a comparable critical acumen with regard to his own ideas. Even so, the picture he drew of the world, in accordance with his conception of its inner essence, is not without a certain novelty and horrific fascination, standing as it does at the opposite pole from all those metaphysical systems that have, in one way or another, endeavored to present ultimate reality as if it were the incarnation of rational or moral order.

For Schopenhauer, the real was not the rational (as Hegel, for instance, implied that it was); on the contrary, “will” was for him the name of a nonrational force, a blind, striving power whose operations are without ultimate purpose or design. So portrayed, nature in all its aspects, ranging from the simplest physical structures to the most complex and highly developed organisms, takes on the character of an endless, and in the last analysis meaningless, struggle for existence, in which all is stress, conflict, and tension. The mechanistic models, the rationalistic schemes and constructions, in terms of which we find it useful to try to systematize the phenomenal data for scientific and practical purposes, merely serve to disguise from view the true nature of the underlying reality; the proper task of philosophy lies, not in seeking (as so many previous thinkers had sought) to reinforce these misconceptions by consoling and sophistical arguments, but rather in removing the veil of deception and setting the truth in a clear light.

HUMAN NATURE. As indicated above, Schopenhauer took as the starting point of his theory of the world the nature of man himself, regarded as the embodiment of will. Man is the microcosm in which all that is fundamental to reality as a whole (the macrocosm) may be plainly discerned. And it is in connection with what he wrote about human nature that Schopenhauer’s doctrine of the will can perhaps be most profitably considered. For this doctrine, far from being merely an extravagant philosophical fantasy, foreshadows much that was central to the later development of psychological theory; it represents a highly significant contribution with genuinely revolutionary implications.

Will and intellect. What Schopenhauer had to say on the subject of human nature revolved about his conception of the role of the intellect in human behavior. We like to suppose that in principle, everything we do lies within the province of our reason and is subject to our control; only if this is so can we deem ourselves to be truly our own masters. Traditionally, philosophers have given their

support to such beliefs; according to Schopenhauer, however, the situation is quite the reverse. For the will is not, as Descartes and others have taught, a sort of instrument or component of the intellectual faculty, mysteriously controlling our actions from on high by means of independent acts of rational choice. As has already been seen, Schopenhauer argued that will and body are simply the same thing viewed under different aspects, and he further claimed that the intellect, far from being the original source and spring of the will and the master of the body, is in fact no more than the will's servant and appendage. From an epistemological point of view, this governance of the intellect by the will manifests itself in the forms of knowledge under which the world appears to us—for example, as a causally governed system. To see things as causes or effects is to see them in terms of their potential uses, that is, as possible means to the gratification of the will.

Motivation. According to Schopenhauer, however, the primacy of will exhibits itself in a number of other important ways. Thus he gave various illustrations, drawn from everyday experience, of the manner in which we are often quite unaware of the true import and significance of our responses to circumstances and situations. Believing ourselves to be activated by some consideration that we find acceptable on moral or other grounds, we miss the real motive and might well be shocked or embarrassed if we knew it. Although we are inwardly and immediately aware of ourselves *as will*, our own consciously formulated conceptions of what we desire or what we are intending are, in fact, a highly unreliable guide when the question under consideration is *what we will*. Sometimes, indeed, Schopenhauer seems to have been making the extreme claim that conscious acts of choice never really determine behavior at all. He suggested in a number of instances that our conduct is not ultimately decided by resolves intellectually arrived at after weighing the pros and cons of alternative courses of action; the real decision is made by the will below the level of rationally reflective consciousness, the sole role of the intellect being to put before the will the various possibilities that lie open to the agent and to estimate the consequences that would ensue upon their actualization. In this sense, we never really form more than a “conjecture” of what we shall do in the future, although we often take such conjectures for resolves; what we have decided to do becomes finally clear to us only *a posteriori*, through the deed we perform. As it stands, this doctrine gives rise to obvious difficulties. Some cases doubtless occur that we should be inclined to describe in some such manner as Schopenhauer recommends, but it does not follow that every case of deliberate

action can be so characterized. Indeed, it may be claimed against all positions of this sort that it is only in virtue of our knowledge of what it is to act in accordance with consciously formed choices that the explanation of certain actions in terms of secret or concealed determinations of the will becomes intelligible.

Unconscious mental activity. The above-mentioned difficulties do not invalidate Schopenhauer's exceptionally perceptive and shrewd observations regarding much human motivation. These observations retain their importance even if the more bizarre speculations he based upon them are rejected; and Schopenhauer in fact connected them with a wider theory of human nature that, considering the time in which he wrote, manifested an astonishing prescience. According to this theory, the entire perspective in terms of which we are disposed to view our characters and doings is distorted. We customarily think of ourselves as being essentially free and rational agents, whereas in fact the principal sources and springs of our conduct consist in deep-lying tendencies and drives of whose character we are often wholly unaware. “Consciousness,” Schopenhauer wrote, “is the mere surface of our mind, of which, as of the earth, we do not know the inside but only the crust,” and in consequence we often put entirely false constructions upon the behavior in which these basic impulses are expressed. He suggested, moreover, that the ignorance we display, the rationalizations which in all innocence we provide, may themselves have a motive, although not one we are aware of. Thus, he frequently wrote of the will as preventing the rise to consciousness of thoughts and desires that, if known, would arouse feelings of humiliation, embarrassment, or shame. Another example of the same process is to be found in instances of memory failure. It is not a mere accident that we do not remember certain things, since there may be powerful inducements for us not to do so; events and experiences can be “completely suppressed,” becoming for us as if they had never taken place, simply because unconsciously we feel them to be unendurable. And in extreme cases this can lead to a form of insanity, with fantasies and delusions replacing what has thus been extruded from consciousness.

Sexuality. Sigmund Freud himself recognized the similarity between ideas like those above and some of the leading conceptions of psychoanalytical theory. Certainly there are striking parallels, and perhaps most obviously between what Schopenhauer had to say about the sexual instinct and the Freudian account of libido. For instance, Schopenhauer claimed that the sexual urge represents the “focus of the will.” Apart from the instinct to survive, it is

the most powerful motive of all and exercises a pervasive influence in every area of human life. Yet despite this, the amount of attention sexuality had received from most philosophers and psychologists had been remarkably small; it is as though a veil had been thrown over it, through which, however, the subject kept showing through. Nevertheless, Schopenhauer was far from extolling the operations of the sexual drive. Although he thought it necessary to expose honestly the stark reality that human beings seek to hide by falsely romanticizing and idealizing their primitive passions, he also made it clear that he considered sexuality to be a source of great mischief and suffering. Thus he referred to it as a “demon” that “strives to pervert, confuse and overthrow everything,” and spoke of sexual desires as being inherently incapable of achieving lasting satisfaction; according to Schopenhauer, the end of love is always disillusion. In other words, here, as elsewhere, conformity to the dictates of the will ultimately results in unhappiness, which is the universal condition of human existence.

PESSIMISM AND ANTIRATIONALISM. In sum, Schopenhauer’s doctrine of the will constituted, in a variety of ways, a reaction against the then dominant eighteenth-century, or “Enlightenment,” conceptions of human nature. He not only rejected the Cartesian belief in the primacy of intellect or reason in man, but also, by implication, repudiated the “mechanistic” model according to which writers like Hume sought to explain human personality and motivation in terms of the combination and association of atomistically conceived impressions and ideas. In place of this model, he substituted one of dynamic drive and function that was oriented toward the biological rather than the physical sciences and that stressed the importance of unconscious rather than conscious mental processes. Furthermore, Schopenhauer’s writings represent a complete departure from the strain of optimism that underlay so much eighteenth-century thinking about history and society. Schopenhauer utterly rejected such ideas as the inevitability of human progress and the perfectibility of man and replaced them with a picture of humankind in general as doomed to an eternal round of torment and misery. Radical changes in the social structure, however “scientifically” applied, would solve nothing, for the evil condition of life as we find it is merely the reflection of the aggressive and libidinous urges rooted in our own natures. All that can usefully be employed are certain palliatives in the form of social and legal controls that give the individual minimal protection against the incursions of his neighbors; and with such measures men have long been familiar.

ART AND AESTHETIC EXPERIENCE

The preeminent position that Schopenhauer assigned to art (certainly no other major philosopher has elevated it to a higher status) is not difficult to understand in the light of his general theory. In this theory, our modes of knowledge and understanding, as well as the activities in which we normally engage, are regarded as being determined by the will. Scientific inquiry was the supreme instance of this, since (Schopenhauer believed) its essential function was one of providing, through the discovery of empirical uniformities, practical techniques for satisfying our wants and desires.

THE AESTHETIC ATTITUDE. The artist’s concern, however, is not with action, or the possibility of action, at all, but with what Schopenhauer termed “contemplation” or “will-less perception.” This type of perception must not be confused with perception of the ordinary everyday kind, wherein things are looked at from the standpoint of practical interest and appear under the aspect of particular phenomenal objects. For it is the mark of aesthetic contemplation that in the enjoyment of artistic experience “we keep the sabbath of the penal servitude of willing”; the world is seen in abstraction from the various aims, desires, and anxieties that accompany our normal apprehension of it, with the result that it presents itself to us in a completely different light.

It is a further consequence of such detachment (and on this point Schopenhauer followed Kant) that all judgments of taste or aesthetic value are disinterested: They cannot have as their basis some titillation of sensual appetite, for instance; nor can they be grounded upon considerations of social utility, or even of moral purpose. To speak of a natural scene or of a work of art or literature as “beautiful” is to judge it in and for itself, and quite outside the framework of cause and consequence within which our ordinary perceptual judgments have their natural place and from which they derive their significance.

THE AESTHETIC OBJECT. The claim that aesthetic awareness presupposes a distinctive attitude of mind and attention is clearly separable from the contention, also advanced by Schopenhauer, that in such awareness the content of our experience is of a radically different kind from that involved in ordinary sense perception. Surprising as it may seem in the light of some of his earlier pronouncements, Schopenhauer held that the subjective conditions that define and universally determine our perception at the everyday level are wholly in abeyance in the case of aesthetic apprehension, and that to this complete

“change in the subject” there is a corresponding change in the object. As aesthetic observers, we are no longer confronted with a multiplicity of individual things and events that are spatiotemporally and causally interrelated, but instead are presented with the “permanent essential forms of the world and all its phenomena,” which Schopenhauer termed the “Ideas” (*Ideen*). This conception of fundamental Ideas, which Schopenhauer adapted from Plato to serve the purposes of his own, very different, theory of art, helps us to understand why he regarded art not merely as a kind of knowledge, but as a kind of knowledge vastly superior to any found in the sphere of the natural sciences. In his view, the natural sciences can never do more than discover regularities at the stage of phenomenal appearance, whereas works of genuine art exhibit to the beholder the nature of the archetypal forms of which the particular phenomena of sense perception are necessarily incomplete and inadequate expressions. Artistic productions may, in fact, be said to be the vehicles through which the artist communicates his profound discoveries and insights and thereby enables others to share his vision.

The notion that the proper objects of artistic perception are Platonic Ideas in the sense described above gives rise to obvious objections. It certainly fits somewhat uneasily into Schopenhauer’s system insofar as that originally seemed to be based upon the postulate that phenomenal representation and noumenal will between them exhaust the field of possible human knowledge. And quite apart from this, the theory of Ideas raises problems on its own account. It appears paradoxical, for instance, to suggest that a picture of, say, apples in a bowl is not a picture of things of the sort we can all see and touch in the ordinary way, but of something set mysteriously apart from these and situated in a realm beyond the range of normal vision.

Even so, it is at least to Schopenhauer’s credit that he recognized some of the difficulties presented by much that we are prone to think and say about artistic portrayals of experience. The concept of perception, for instance, seems to play a significantly different role in the context of aesthetic appraisal and criticism from the role it plays in other contexts. Again, the specific sense in which certain art forms (painting, for example) are concerned with “representing” reality is notoriously difficult to analyze. The claim that the artist sees something literally distinct from what we ordinarily see is, no doubt, hard to defend; on the other hand, the (different) claim that he sees and is able to portray ordinary things in unfamiliar ways, and under fresh and revealing aspects, appears to contain an obvious truth.

Schopenhauer himself never clearly distinguished between these two claims. Theoretically he subscribed to the first, but much that he said in his discussion of concrete cases accords better with the second. Not only did he often stress the particularity of the artist’s observation of phenomena; he also suggested that the artist’s unique mode of presenting individual objects, scenes, or situations succeeds in illuminating for us whole ranges of our experience to which we have previously been blind. He argued, however, that it would be a mistake to suppose that we can ever convey by verbal description what we learn from our direct acquaintance with particular works of art. For what these works communicate will in the end always elude anything we try to say about them. “The transition from the Idea to the concept,” he wrote, “is always a fall.”

MUSIC. Schopenhauer thought that all forms of artistic activity—with one important exception—could be understood and explained in terms of his theory of Ideas. The exception was music. Music is not concerned with the representation of phenomena or the fundamental forms that underlie phenomena, but has as its subject the will itself, the nature of which it expresses directly and immediately. Thus, of all the arts, music stands closest to the ultimate reality of things that we all bear within ourselves and speaks “the universal imageless language of the heart.” Schopenhauer’s ideas, in this instance and in general, produced a deep impression upon Richard Wagner, who in his opera *Tristan und Isolde* tried to realize in musical form the leading conceptions of Schopenhauer’s theory of the world. It is a curious irony that Schopenhauer, far from reciprocating Wagner’s admiration, spoke of his music with actual distaste.

ETHICS AND MYSTICISM

Although the world, viewed from a purely contemplative standpoint, presents a spectacle that can be aesthetically enjoyed, it does not follow that the operations of the agency which underlies all that we perceive can afford us any kind of moral guidance or solace. On the contrary, the ethical significance of existence lies in its ultimate horror. Unlike many other metaphysicians, Schopenhauer concluded from his system, not that we should gratefully seek to make our lives conform to the pattern implicit in the nature of reality, but rather that true salvation consists in a total rejection of this pattern. The moral worth of individuals lies in their capacity to liberate themselves from the pressures and urges of the rapacious will.

INALTERABILITY OF CHARACTER. It is not altogether easy to see how liberation is possible. Schopenhauer had claimed that human beings, like everything else in nature, are in essence expressions of will. How, then, can they become otherwise? Furthermore, he insisted upon a strictly deterministic interpretation of human character and action, one that makes the type of freedom of choice postulated by traditional libertarian doctrines inconceivable. What a person does is always and necessarily a manifestation of his inner disposition, which remains fixed and is unalterable by any resolutions he may form to be different. The individual discovers what he is really like by observing his behavior over the course of his life. He will find that this behavior conforms to certain invariant patterns of reaction and response, so that if the same circumstances recur, his conduct in the face of them will be the same as it was before. Such consistent behavior patterns are the outward manifestation of the individual noumenal essence, or timeless character, which each man is in himself—a conception Schopenhauer claimed to have derived from Kant's discussion of the foundations of moral responsibility, though the consequences he drew from it were in fact far removed from any drawn by Kant. Nor can some of these consequences be said to have been logically very happy; for instance, Schopenhauer seems to have employed the notion of a man's character so elastically that it ruled out the possibility of any imaginable state of affairs falsifying his thesis concerning its innate and unchangeable nature.

ETHICAL VARIATION. Schopenhauer's claim that a man cannot change his character at will does not, however, commit him to the view that the dispositions of different individuals do not show significant ethical variations. For an explanation of the fact that there are good as well as evil persons in the world, he returned to the fundamental tenets of his metaphysic. It is a feature of the good, as contrasted with the self-centered or egotistical, individual that he comprehends himself and his relations with others from a "higher" standpoint, which enables him to recognize, however obscurely or inarticulately, the common unitary nature shared by all things. Egoism rests upon the assumption that the individual is a self-sufficient unit, to which all else is foreign. But the individual appears to be set apart from his fellows by an impassable gulf only when apprehended in accordance with the spatiotemporal scheme that informs our everyday "will-governed" way of looking at things.

A profounder insight, such as is exhibited intuitively in the behavior of the just and compassionate man who "draws less distinction between himself and others than is

usually done," involves awareness of the illusory character of the phenomenal world. Those who possess this awareness no longer see their fellow creatures as alien objects to be overcome or manipulated in pursuit of their own ego-centric aims, but rather as "themselves once more," homogeneous with their own being and nature. Thus, in the last analysis, the distinction between virtue and vice has its source in radically different modes of viewing those around us; and this distinction could, Schopenhauer believed, be adequately explicated and justified in the terms provided by his own philosophical system.

DENIAL OF THE WILL. Schopenhauer frequently quoted the Brahman formula, *tat tvam asi* ("that thou art"), when discussing the metaphysical unity of things that underlies the realm of appearance. Indeed, all his writings on ethical and related subjects show affinities with the doctrines advanced in the Upaniṣads and in Buddhist texts—affinities that he freely acknowledged. Like the Indian teachers, he considered all human life to be enmeshed in suffering, and following them, he often used the word *māyā* to refer to the illusory phenomenal world to which, as empirical individuals, we belong. Total release from the enslavement of the will, as compared with the identification of himself with others that is displayed in the conduct of the morally good man, in fact occurs only when a person finally ceases to feel any attachment to earthly things and when all desire to participate in the life of the world completely vanishes. Such an attitude of mind, which Schopenhauer attributed to ascetics and mystics of all times, becomes possible when a man's will "turns and denies itself," and when what in the eyes of ordinary men is the very essence and substance of reality appears to him as "nothing."

But Schopenhauer was insistent that this "turning of the will," which is a highly mysterious process, is not something a man can bring about through his own deliberate volition, since the process involves the complete "abolition" of his previous personality. This "turning of the will" comes to him, as it were, "from outside" and springs from an insight that wholly transcends the will and the world. Such mystical insight, moreover, is necessarily incommunicable and indescribable; all knowledge, including that attainable by philosophy, here reaches its limit, and we are left with only "myths and meaningless words" that express no positive content. "The nature of things before or beyond the world, and consequently beyond the will," Schopenhauer declared at the close of his main work, "is open to no investigation." The end of philosophy is silence.

IMPORTANCE AND INFLUENCE

Schopenhauer's critics have not failed to draw attention to discrepancies and inconsistencies in his system. These certainly exist, and his natural clarity of expression, which contrasts so sharply with the obscure and cloudy terminology favored by his philosophical contemporaries in Germany, makes them comparatively easy to detect. On the other hand, these discrepancies should not be allowed to stand in the way of a proper appreciation of what was important and influential in Schopenhauer's thought. The nineteenth century witnessed a decline in the fascination that achievements in physics and mathematics had previously exercised over philosophy, and there was a tendency in speculative thought to explore new ways of interpreting and conceptualizing human life and experience. In this development Schopenhauer played a central role. Both through his theory of will, with its psychological implications, and also through the new metaphysical status he gave to art, he helped to bring about a profound shift in the intellectual and imaginative climate.

In this connection, the impression made by his ideas upon novelists such as Lev Tolstoy, Joseph Conrad, Marcel Proust, and Thomas Mann is particularly noteworthy. Among philosophers, the impact of Schopenhauer's thought was weaker and certainly never approached that produced by Hegel's writings; while in more recent times, when philosophical speculation in general has been at a discount, he has attracted little interest. Yet such neglect is undeserved, and the significance of his contribution should not be underestimated. He realized more fully than the majority of his contemporaries the implications of the Kantian critique of traditional metaphysics, and some of the things he himself had to say about the nature of a priori knowledge have a strikingly modern ring. Again, it is worth emphasizing his "instrumentalist" view of human thinking, which anticipated William James and the American pragmatist school, and also his highly perceptive attacks upon the Cartesian theory of personality and self-consciousness, which in important respects foreshadowed present-day approaches to problems in the philosophy of mind. (In particular, his theory of the double knowledge we have of ourselves as agents in the world has interesting contemporary analogues.)

Finally, it should be remembered that possibly the greatest philosopher of modern times, Ludwig Wittgenstein, read Schopenhauer and was influenced by him. The extent of this influence appears most clearly in the notebooks Wittgenstein kept during World War I (*Notebooks 1914–1916*, translated by G. E. M. Anscombe, Oxford,

1961), but signs of it are also to be found in the *Tractatus Logico-Philosophicus* (translated by D. F. Pears and B. F. McGuinness, London, 1961), particularly in the sections on ethics and the limits of language in the latter part of the work.

SCHRÖDINGER, ERWIN

(1887–1961)

Erwin Schrödinger was born in Vienna, Austria. After his years at the Gymnasium, where he was given a strong education in classics and in science, he studied physics and mathematics at the university of Vienna from 1906. His major teachers were the successors of Ludwig Boltzmann: Franz Exner and Fritz Hasenöhr. Schrödinger's early interest for philosophy is evident in several manuscripts of this period, which contain reflections about Greek and Indian thought and British empiricism. He was then awarded the D. Phil. Degree in 1910 and became assistant experimental physicist in Exner's laboratory in 1911. From this date until 1922, he worked on several subjects, including atmospheric radioactivity, statistical physics, psycho-physics of sensations, general relativity, and atomic physics.

At the end of World War I, in which Schrödinger served as an artillery officer in the Austrian army, he devoted one year to studying philosophy. He wrote down his philosophical reflections later, during the summer of 1925, in an essay that became part one of his book *My View of the World*. After brief appointments in various German universities, he became full professor of theoretical physics at the university of Zurich in 1922. In the autumn of 1925, he formulated wave mechanics, construed as a development and alteration of Louis de Broglie's ideas. In 1926 Schrödinger published classic papers in which he formulated and solved the "Schrödinger equation" and demonstrated the empirical equivalence between wave mechanics and Werner Heisenberg's matrix mechanics.

Schrödinger then succeeded Max Planck at the prestigious chair of theoretical physics of Berlin in 1927. But he left Berlin to go to Oxford in mid-1933, a few months after Hitler's rise to power. The same year, he shared the Nobel Prize for physics with Paul Dirac. During his two years at Oxford, he wrote several important papers about the interpretation of quantum mechanics, presenting for the first time the concept of "entanglement" of states and the "cat paradox." Schrödinger then accepted an appointment at the University of Graz in Austria in 1936. But with the advent of the "Anschluss" in 1938, Schrödinger had to flee once more from the Nazis. After spending some time in Vatican and in Belgium, he received an appointment in 1940 at the Dublin Institute for Advanced Studies. The Institute was founded mainly for him by Eamon de Valera, then prime minister of the Irish Republic. During his stay in Ireland, Schrödinger devoted his work to unified field theories (in Einstein's spirit), to renewed reflections on the interpretation of quantum mechanics, and also to conferences for a broader audience. His well-known books *What Is Life?*, *Nature and the Greeks*, and *Mind and Matter* arose from these conferences. In 1956, Schrödinger returned to Austria, where he retired in 1958. He died in Vienna in January 1961.

PHILOSOPHY OF PHYSICS

The key to Schrödinger's philosophy of physics (especially quantum mechanics) is contained in a letter to Arthur Eddington of March 22, 1940. There, Schrödinger insists that Ernst Mach's radical empiricism and Ludwig Boltzmann's taste for rational "pictures" are not mutually exclusive strategies. He regarded Mach's empiricism as a good guide to *tabula rasa* whenever unwarranted old intellectual constructs hinder a proper understanding of new physical phenomena. But this is only the first step of

research. Boltzmann's urge to picture must be the second step. Indeed, "forming absolutely clear, almost naively clear and detailed "pictures" allows one "to be quite sure of avoiding contradictory assumptions." (*The Interpretation of Quantum Mechanics*, 1995, p. 121).

Schrödinger used both methods. He was clearly inspired by Mach's method when he criticized vehemently the old-fashioned concept of "particle" construed as a small permanent material body. He formulated his criticism as early as 1913, when he first heard of Bohr's model of the atom, and then refined it throughout his career. According to Schrödinger, the concept of an object is constructed out of actual observations complemented with appropriately selected virtual observations. But if the interpolation of arbitrarily numerous virtual observations is not allowed by the most advanced predictive theory, then the very process of construction collapses, and the corresponding object *cannot be said to exist*. For elementary particles, "Observations are to be regarded as discrete, disconnected events. Between them there are gaps which we cannot fill in" (*Science and Humanism*, p. 27). We cannot fill them in according to a trajectory pattern, because of Heisenberg's uncertainty relations. But if there is no trajectory, the discrete events cannot be tied up into a spatio-temporal continuant. Therefore, the idea that these scattered events reveal some permanent being is a sort of kinetic *illusion*: particles *do not exist*.

After this Machian preliminary move, however, Schrödinger activated the Boltzmannian side of his philosophy of physics. To him, without a precise picture, scientific thought is threatened with ambiguity. Yet the picture must not be taken as mere mimicry of "things out there." It is nothing more than the most efficient *mental tool* we have, with no ontological implications. This is the status Schrödinger ascribed to his *wave function* in the 1950s, after having apparently held a naively realist belief in the existence of ψ -waves in 1926. His mature view of wave functions was expressed in *Science and Humanism* (p. 40): "We do give a complete description, continuous in space and time ... a description of something. But we do not claim that this 'something' is the observed or observable facts; and still less do we claim that we thus describe what nature ... really is." Yet the description, or picture, must be taken seriously in view of its epistemological value. Its continuous evolution according to the Schrödinger equation and the entanglement between wave functions must be allowed to develop throughout without any sudden "reduction of the state." The only constraint to be exerted on this picture is that it must have some connection with experimentally observable

events. But to secure this connection, it is sufficient to use either a rule about expectation values of observables or Born's probabilistic rule: *no reduction, no "quantum jump," no collapse of the wave packet, is needed*. This is Schrödinger's "solution" (or rather "dissolution") of the *measurement problem* of quantum mechanics.

METAPHYSICS

Schrödinger was usually careful to separate his metaphysics from his scientific work. He held that Western science arose from the act of "objectivation"—the act of withdrawing oneself from the domain under study. By this objectivation, we push aside color, pain, esthetic judgment, and ethical values, and restrict our interest to that which is common to all: numbers and structures. But, Schrödinger argues, there is no real duality between ourselves and the objects we have thus posited. Furthermore, our personal selves are identical with the one all-comprehending universal self. Whereas science is only concerned with the relations between objectified entities, metaphysics ventures to say something about the one that comes before any objectification has taken place. This nondualist conception (which Schrödinger called the "identity theory") was overtly borrowed from the Indian *Advaita Vedānta* and was remarkably similar to Schopenhauer's earlier views. The arguments Schrödinger presents in favor of this view are as follows: (i) The truth of the "identity theory" is somehow directly experienced; (ii) The "identity theory" provides us with a coherent picture of the world as a whole, including the vexing mind-body problem; and (iii) The "identity theory" has a potentially high ethical value, because it cuts egocentrism at its root. The only point of contact between Schrödinger's metaphysics and philosophy of physics is negative. In *Mind and Matter*, Schrödinger sharply criticized Heisenberg's suggestion that quantum mechanics had weakened the Cartesian dichotomy between *res cogitans* and *res extensa*. After all, Schrödinger wrote, "Subject and object are only one. The barrier between them cannot be said to have broken down as a result of recent experience in the physical sciences, for this barrier does not exist."

SCHULTZ, JULIUS

(1862–1936)

Julius Schultz, the German philosopher, dramatist, historian, and philologist, was born in Göttingen. From 1888 until 1927 he taught at a high school in Berlin. Among Schultz's numerous writings dealing with philosophy, the most important are *Die Maschinentheorie des Lebens* (1909) and *Die Philosophie am Scheidewege* (1922).

Schultz's starting point is the question How must we conceive of consciousness, on the one hand, and the object, on the other, if we wish to understand from their combined action the world of phenomena? To answer the psychological part of this question, Schultz first studied the axioms and categories of ordinary and of scientific thinking in order to see what attitude toward the phenomena is forced upon our understanding by its own innermost essence. At the same time he found a solution to the epistemological problem, namely, that if we desire not only to describe the world scientifically but also to understand it uniformly and completely, we must reduce all qualitative differences to quantitative ones. Accordingly, we must interpret the world of sense as a world of motion and explain all the happenings in the world in a mechanistic-dynamistic manner.

In epistemology, Schultz acknowledged special indebtedness to Immanuel Kant and Hans Vaihinger, whose views he interpreted and developed in a psychological fashion. His philosophy of nature is characterized

by the attempt to outline a thorough and systematic causal-mechanistic worldview. The nucleus of this view is a "machine theory of life," which Schultz developed on a broad scientific basis. The theory explains the phenomena of life with the help of the postulate of "biogenes." These are defined as unobservable molecules of submicroscopic size, which are not themselves alive but which build up the living forms. Schultz conceived of the "biogenes" in such a manner that from their joint action one can understand all the processes of life in their goal-directedness and wholeness, and thus both the forms as well as the functions of organisms. In this biomechanistic conception, organic forms are extremely complicated physicochemical systems. The goal-directed course of living processes arises out of the meaningful arrangement of these systems, and their structure and behavior are explained by strictly causal natural laws, making unnecessary the assumption of immaterial vital forces.

Schultz also contributed to the typology of philosophical thought. He sought to reduce all philosophical standpoints to two basic conceptions of the world and of life, corresponding to two different types of men. The first type pays homage to the value of conservation and prefers purposeful, useful activity; as a thinker, this practical-minded man professes an ethics of duty and believes in progress and in the efficacy of metaphysical forces. The second type prefers the value of formation and as an aesthete or theorist playfully seeks a sympathetic understanding of forms, which he desires to behold in their abundance. He professes an ethics of character, or ethics of the beauty in life, and believes in an eternal recurrence of coming into being and ceasing to be. As an advocate of determinism and causality, he envisages a mechanistic picture of the world in order to understand it in its depth. Schultz himself preferred the second standpoint, which determined his attitude in the philosophy of history. In particular, he took a pessimistic view of the future development of culture. He feared that man would become part of a machine, a socialized worker-ant—organized for common work down to the last detail, but, as in the early ages, without a history.

Franz Austeda (1967)

Translated by Albert E. Blumberg

SCHULZE, GOTTLOB ERNST (1761–1833)

Gottlob Ernst Schulze, the skeptic and critic of Kantian philosophy, was born in Heldrungen, Thuringia. He was professor at Wittenberg and Helmstedt and later at Göttingen, where one of his students was Arthur Schopenhauer. His influence is due chiefly to his writings, in which he developed his critical-skeptical position. Schulze's main work, and the one that made him famous, was *Aenesidemus*. In this work, which first appeared anonymously and without the place of publication, Schulze presents objections to the Kantian critique and to K. L. Reinhold's intended vindication of the critical philosophy. Schulze's arguments against the critical philosophy led him to share David Hume's skepticism, of which he gave a concise presentation.

The *Aenesidemus* tries to show that Hume's skepticism has not been refuted by the critical philosophy. However, Schulze's position is not that of absolute skepticism: The validity of formal logic and the principles of identity and contradiction are not subject to doubt. He defined skepticism as the doctrine "that philosophy can establish neither the existence nor the non-existence of things-in-themselves and their qualities. Also the limits of our cognitive capacity cannot be fixed and ascertained on the basis of generally valid principles. ... But the reality of presentations and the certitude of mental events immediately given through consciousness no skeptic has ever doubted" (*Aenesidemus*, p. 24). On the other hand, "skepticism does not declare the metaphysical questions to be eternally unanswerable and in principle not liable to a solution" (p. 24). Through progressive development it is possible to approach a solution of the problems concern-

ing the existence or nonexistence of things-in-themselves and the limits of our cognitive capacities.

Thus the possibility of perfecting human cognition so as to attain clarity and certitude in particular metaphysical questions was not denied by Schulze. However, his objection to the critical philosophy was not limited to the question concerning the possibility of progress in metaphysics; he also attempted to show the self-contradictory nature of Immanuel Kant's critical philosophy. The critical philosophy argues that since general and necessary knowledge is possible only through synthetic a priori judgments, such judgments must represent reality. Furthermore, such judgments are possible only on the assumption of a pure capacity of understanding; hence, such a capacity must exist. In interpreting Kant, Reinhold generalized this mode of argumentation, formulating the fundamental principle that the presentation of any object implies the distinction between consciousness of the subject, of the object, and of the relation obtaining between them. From these indispensable components of the presentation Reinhold concluded the reality of corresponding objects.

However, from the fact that presentations always contain the notions of subject, of object, and of their relation to each other it is illegitimate, according to Schulze, to conclude the objective reality of corresponding objects. The transition from thought to being is grounded in ontological thinking, which Kant himself showed to be defective in his criticism of the classic proofs for the existence of God and of dogmatic metaphysics. Since one cannot argue from the conditions of thought to the reality of objects, the problem of philosophy is, according to the critical philosophy, to search for the competence and the legitimacy of our thought to determine objects of reality. The task of the Kantian critique is to show the objective validity of our judgments. However, the indispensable conditions of thought constitute subjective necessity, from which objective validity cannot be derived.

Furthermore, "it is presupposed that each part of human cognition must be grounded in reality as its cause. Without such an assumption the doctrine of the *Critique* concerning the origin of the necessary judgments has no meaning whatsoever" (*ibid.*, pp. 137f.). The conclusion from the necessary judgments in our consciousness as to the reality of objects is based on the principle of causality. Existing objects constitute the causes of our cognition. The category of causality is thus employed with reference to noumena. Also, in the conception of sensibility as a faculty of receptivity, the existence of things-in-them-

selves that have the capacity to affect our sensibility is presupposed. Here again the concept of causality is applied to noumena, while, according to the critical philosophy, causality as a category of understanding is confined to the realm of phenomena. Reinhold's doctrine that things-in-themselves, although not cognizable, are nonetheless thinkable, is untenable. Since the things-in-themselves are thought to be the cause of cognition, they are cognized as having the capacity to affect the knowing and thinking capacity. The thing-in-itself must be cognizable, or it cannot be considered as a cause of cognition.

Likewise, the concept of causality cannot be employed for proving the reality of the subject as a thing-in-itself. Schulze understood the Kantian solution of the question "How are synthetic a priori propositions possible?" as consisting in the derivation of these propositions from the subject as their cause: "The *Critique* derives the necessary synthetic propositions from the subjective mind (*Gemüth*) and its a priori determined cognitive processes ... by the application of the principle of causality, which does not harmonize with its own principles delimiting the area of application of the categories" (ibid., pp. 153f.). Moreover, the conclusion from the propositions to the reality of a capacity in the mind does not explain the process of cognition. Nothing is gained by proposing that the perception of the material given is due to a receptive capacity, for a problem is not explained by reducing it to something unknown. The problem of cognition of experience is not solved by a reduction of cognition to a receptive capacity that is no less problematical.

Schulze considered the a priori concepts as existing in time "prior" to the cognition of objects. This account of the a priori concepts as innate ideas and as inherent qualities of the subjective mind is a misunderstanding of the Kantian position that has been common to numerous interpreters of Kant until the present. Schulze thus failed to understand the essence of the critical philosophy, which does not aim at deriving the synthetic propositions from the subject as a thing-in-itself. Kant was not concerned with the psychological process of cognition but with objective cognition, as manifested in the scientific process. The problem is how synthetic a priori propositions are possible in mathematics and science, and not how the human mind as a subject conceives such propositions. The objectivity of the judgments is vouchsafed by the scientific laws determining objects that arise through these laws. This is implied in the Kantian principle of the "possibility of experience." Scientific experience is possible only through synthetic propositions. Since without

synthetic propositions there would be no scientific experience at all, their legitimacy is vouchsafed by the function they fulfill for experience. Furthermore, Schulze held the difference between synthetic and analytic propositions was not an objective distinction, and, psychologically considered, it depends on subjective circumstances whether a proposition is synthetic or analytic for a particular individual at a certain moment.

Schulze's criticism of Kant implied the notion of the subject and predicate of the proposition as individually given and fixed entities, so that the synthetic proposition connects elements that can be thought of in themselves. Hence, the concepts of the subject and the predicate must be thought of as separately given, and the question is how their connection can be of a necessary nature. Schulze did not realize that for Kant the concept of the subject arises by its determination through the synthetic proposition. In the proposition "*S is P*," *S* is an unknown before its determination through *P*. The investigation of *S* is a "doubt-inquiry process" (John Dewey's expression); *S* acquires determination only through the predicate. Schulze's criticism is thus predicated upon an understanding of the critical philosophy as subjective idealism with the notion of a priori concepts as innate ideas, which leads to dogmatic assumptions concerning the application of the concept of causality to things-in-themselves. The a priori concepts in the critical philosophy are not to be understood as constituent features of the subjective human mind but as creative functions of thought in the process of ordering experience.

Schulze was also critical of Kant's conception of moral theology. He raised objections to the Kantian doctrine of the postulates (God, freedom, immortality) as formulated in the *Kritik der praktischen Vernunft*. From the sense of the moral command in us, the categorical imperative, there can be no conclusion as to the reality of a most perfect being. As ideas of reason, God, freedom, and immortality are endless tasks for human activity, but by the conception of these ideas as postulates their real existence as objects is posited. "The Kantian moral theology postulates *more* than what practical reason demands for the satisfaction of its requirements" (ibid., pp. 440ff.). In his criticism of the postulates Schulze has partly anticipated the neo-Kantianism of the Marburg school. Hermann Cohen, for example, although motivated by different considerations, has pointed out that the regulative ideas of reason do not require the support of the doctrine of postulates.

Schulze's contribution to the development of Kantian idealism consists in his exposing the contradictions

and inconsistencies involved in both dogmatic-realistic and subjective-idealistic interpretations of the critical philosophy, but his attempt at a vindication of Hume's skepticism proved ineffective for further development of Kantian idealism. Philosophical thought took the course not back to Hume but to a more consistent critical idealism eliminating the concept of a thing-in-itself (as in Salomon Maimon) and to speculative idealism as it developed in the post-Kantian metaphysical systems. However, by his valuable criticism of the doctrine of the faculties of the soul Schulze anticipated Johann Friedrich Herbart and influenced Friedrich Eduard Beneke (1798–1854).

According to Schulze, a phenomenon of the life of the soul is not explained by attributing it to a "faculty." Such an attribution does not explain, but merely gives another name to the same thing. The task of psychology as a science is, rather, a detailed description of actual mental occurrences and their systematic classification. By such a method, general concepts of psychological phenomena can be attained; but they should not be attributed to "faculties" of the soul, which is a metaphysical concept.

SCHUPPE, ERNST JULIUS WILHELM

(1836–1913)

Ernst Julius Wilhelm Schuppe, the German philosopher, was born in Brieg, Silesia. He studied at the universities of Breslau, Bonn, and Berlin, and he took his doctorate at Berlin in 1860. He taught at grammar schools in Silesia and then held a chair of philosophy at the University of Greifswald from 1873 to 1910.

EPISTEMOLOGY

In his main work, *Erkenntnistheoretische Logik* (Bonn, 1878), largely anticipated by his earlier book *Das menschliche Denken* (Berlin, 1870) and summarized in his later *Grundriss der Erkenntnistheorie und Logik* (Berlin, 1894; 2nd ed., Berlin, 1910), Schuppe was concerned with the epistemological bases of knowledge generally and of logic in particular. Schuppe held that a theory of knowledge should avoid hypotheses such as the transcendent reality postulated by realists and metaphysicians, but that it should equally avoid one-sided objective or subjective foundations of knowledge, whether materialist, positivist, or idealist.

In keeping with these requirements, Schuppe developed the notion of conscious immanence (*Immanenz, Bewusstsein, Ich*) in which subject and object form a unity. This immanence of consciousness, or ego, is a fact (*Tatsache*) that is given with certitude and can therefore serve as a starting point for epistemology. Only abstractly can the ego be divided into subject and object; concretely it is a correlation of the two. This is not to say that the object is a psychic entity, but merely that there is no being not related to a subject. To ignore the correlation would

be to incur a contradiction because a supposed unthought entity is nevertheless implied in the thought of the epistemologist.

To account for the distinction and division of consciousness and content (*Inhalt*), and of contents among themselves (subjective elements such as acts are distinct from objects of acts, however much both may have to be considered contents for an abstract subject), Schuppe presented a theory of “common” content: Objective content is a given that can be shared by several, whereas subjective content (sensation, for example) is unique and private. The need for this division led to a theory of consciousness in general (*Bewusstsein überhaupt*) as distinguished from the consciousness of a concrete individual subject. Individuality is based on content not shared by others. Other minds, which are presupposed by the notion of consciousness in general, are known, Schuppe claimed, by inference mediated by one’s own body; but he also asserted that they can be regarded as immediately perceived. Schuppe denied the claim that other minds are immanent contents of one’s mind—like any other object—as being tantamount to solipsism. Schuppe drew upon the ontic fact of a plurality of minds as a basis for consciousness in general.

Schuppe held that thought is also a “component” of the content of consciousness, along with the sense component; it “accedes” to perceptual data. Accordingly, objects of cognition can be considered as constituted by an interaction of an original given of sense, by itself an abstraction, with performances of thought (*Denkarbeit*). In fact Schuppe came to regard thought as the central function of consciousness: To think is to appropriate content, to receive an impression in its positive determinacy, to fixate it as identical. This primary performance of appropriation is thought-in-general, which is prior to judgment. Schuppe argued that at this stage there is only one datum to be appropriated but that for judgment two contents, subject and predicate, are required. (Here Schuppe was influenced by a grammatical notion of judgment.) Continuing to develop his notion of content, Schuppe introduced an analysis of content in which thought stands for the identification of two contents (an instance of the principle of identity, with the principles of contradiction and limitation as corollaries) and, somewhat surprisingly, for the establishment of causal connection between them. Identity and causality are the categories that constitute objective content. (Here Schuppe was guided by a metagrammatical or transcendental notion of judgment, interpreting the category as the predicate of the unified contents.)

ONTOLOGY

With this basis of transcendental thought, Schuppe’s “epistemological” logic was not so much concerned with the “forms” of formal logic as with the establishment of a priori truths about the object of knowledge. Thus the logic constitutes a theory of objects, an ontology. Schuppe analyzed the given into its elements (temporal and spatial determinateness, sense impression) and conceptual moments (genera and species), and distinguished several kinds of union (*Zusammengehörigkeit*) among them. In a transcendental progression Schuppe established number, space region, thing, organism, and artifact; and genera, species, and matter. He avoided any reference to a transcendent cause. Understandably, he presented a coherence theory of truth.

LOGIC

Schuppe sought a transcendental genealogy as a basis for logic. This project involved a certain deviation from the traditional understanding of formal logic. He rejected the isolation in logic of a purely formal realm, denying in fact that purely formal theorems are significant. He regarded propositions as assertions of categorial unification. Logic must be concerned with the realm of material content in which unity is asserted and must examine the various types of union of content, that is, the “real” genera of content, which, in the case of objects of appearance, are grounded in the causal context. This doctrine has ramifications in many areas of logic, for example, in the theory of definition.

Schuppe’s theoretical philosophy can be regarded as a doctrine of the constitution of knowledge and its objects by transcendental synthesis. In view of its intuitive starting point and its analysis of given content, however, it seems to be a compromise between a logico-transcendental theory and a theory of reflective intuition. The agency responsible for the grounding of objectively constituted content is both a transcendental principle and an existent consciousness. The normative element of a transcendental theory is merged with the factual basis of a subjective ontology. Schuppe’s philosophy thus stands between transcendental critique and ontological philosophy of immanence. Although it leans heavily on Immanuel Kant, it anticipates much of Edmund Husserl’s phenomenology and constitutes an example for a theoretical understanding of the interplay of factuality and logico-transcendental thought.

PRACTICAL PHILOSOPHY

Schuppe's *Grundzüge der Ethik und Rechtsphilosophie* (1881; reprinted 1963) offers an independent compromise between a normative position, based on the will as a form of consciousness in general, and a eudaemonistic one, based on pleasure. He also wrote several studies in the philosophy of law, such as *Der Begriff des subjektiven Rechts* (Breslau, 1887), and joined the philosophical discussion concerning the new German civil code (*Das Gewohnheitsrecht*, Breslau, 1890; *Das Recht des Besitzes*, Breslau, 1891).

Klaus Hartmann (1967)

SCHUTZ, ALFRED

(1899–1959)

Alfred Schutz was born in Vienna on April 13, 1899. He studied law and social sciences at the University of Vienna from 1918 until 1921, where he completed a doctorate in law and then continued his studies in the social sciences until 1923. Equally as important for his intellectual development as his studies at the university was his participation in the informal academic life of Vienna, in which he also cultivated his philosophical interests. After completing his academic studies and in addition to his ongoing scholarly activities, Schutz held the full-time job of a bank lawyer—a dual life that lasted until he retired from the bank in 1956. Following the annexation of Austria to the Third Reich, Schutz and his family escaped via Paris to New York. There he became affiliated with the graduate faculty at the New School for Social Research in New York, where he taught from 1943 until 1952 as a lecturer, then afterwards as a full professor of sociology and from

1956 as professor of both sociology and philosophy. He died on May 20, 1959, in New York.

Schutz is regarded as the founder of the phenomenological approach in sociology. Influenced by Max Weber, Henri Bergson, Edmund Husserl, the Austrian School of Economics, and pragmatism, he sought to give a philosophical foundation to interpretative social sciences. As a critical follower of Husserl, he developed his own *mundane phenomenology* of the life-world and its structures, showing how actors produce and understand social reality in everyday interactions and communication.

Schutz begins with Max Weber's view of social reality as a meaningful sociocultural world and shares his concept of meaning-oriented social action, but he criticizes Weber for neglecting to inquire into the constitution of meaning in general. In order to analyze how the meaning attached to action is revealed, Schutz refers to the philosophical concepts developed by Henri Bergson and Edmund Husserl. He adopts the Bergsonian idea of the stream of consciousness, but he later comes to recognize difficulties in Bergson's intuitivism and turns to Husserl's phenomenology.

In 1932 Schutz writes his masterpiece “Der sinnhafte Aufbau der sozialen Welt” where he develops his basic concept of the constitution of the social world and formulated his own phenomenological position. Influenced by pragmatism—which was mediated to him by Henri Bergson, Max Scheler, and William James—in this work he proceeds beyond the realm of consciousness and perception as analyzed by Husserl and considers both human action and interactions as well as acts of consciousness as factors in the constitution of meaning. Leaving behind the transcendental philosophical approach, he develops his own “mundane” phenomenology that analyzes the constitution of a meaningful world within “mundane” social relationships in the everyday world. He adopts the results of the Husserlian analyses of the temporality of consciousness, of the intentional structure of lived experience, as well as of the meaning constitution based on embodiment as preconditions on which the social shaping of experience patterns is based, but he rejects Husserl's assumption that intersubjectivity in the sense of understanding of the others could be a result of the acts of consciousness alone (Schutz 1966). Rather, he shows how the schemes of experience are shaped by influencing (*Wirken*) and by relationships of influence (*Wirken-beziehung*) which consist of interaction and communication.

Schutz understands communication as a process where two subjective streams of consciousness are coordinated within a relationship of mutual influence and where the meaning of one ego's action consists in the intention to evoke a reaction on the part of the other. Actions have here the function of signs that are mutually indicated and interpreted. Because the final meaning of one person's action is revealed in the reaction of the other and vice versa, communication provides a common stock of shared patterns of interpretation that allows for mutual understanding, even if each of the agents always refers to his or her own schemes of experience. In this concept of understanding based on interaction, Schutz offers his own solution to the problem of intersubjectivity posed by Husserl.

In his later work Schutz (1962, 1964, 1966) determines this communicatively created social reality as the world of everyday life whose typical patterns are taken for granted and represent the intersubjective common core of the reality in which people live. He also discloses further structural characteristics of this everyday core of the life-world: Its typical structure depends considerably on the pragmatic orientation of action selecting the areas where typification processes take place (1962, 1966, 1970). Both typicality and this selection based on *systems of relevance* represent two generative principles of order in the everyday world. This everyday reality is nevertheless not identical to the life-world as a whole. By suspending his pragmatic interest, the agent is able to modify his or her everyday experiences and perceive them as objects of a game, fantasy, art, science, or as a dream. All those modifications represent different provinces of meaning that transcend the everyday world and constitute the *multiple realities* (Schutz 1962) of which the life-world is composed. The different strata of meaning in the life-world are integrated by semiotic systems whose structure allows the contents of one province of meaning to be symbolized by another through appresentation.

By considering communication as a substantial constitutive mechanism of social reality, Schutz (1962) stresses the role of language in this process. On his view, language maintains relevances and typifications unique to specific cultures and to social groups and is thus crucial for the constitution of the life-world as a cultural one (Schutz and Luckmann 1989).

The methodological rule that Schutz derives from his approach is expressed in his *postulate of adequacy* (Schutz 1962, 1964) between everyday and scientific typifications. This postulate holds that higher-order interpretative types employed by social sciences have to be constructed

in correspondence to the structure of the everyday typifications (first-order types). Thus the structure of the life-world that guides everyday actions also represents the methodological framework within which the social and cultural sciences have to proceed.

The Schutzian phenomenological approach represents one of the main paradigms in the area of interpretative social and cultural sciences. In philosophy his theory led to a critical assessment of the Husserlian view of intersubjectivity, to conceptions of a worldly phenomenology and theory of the cultural sciences (Embree 1988), and to a philosophy of modern anonymity (Natanson [1962–1995] 1986), as well as to new insights into intercultural hermeneutics (B. Waldenfels 1997, 1998, 1999). It also influenced the philosophy of gender (E. List 1993). In a modified form, Schutz's concept of the life-world was also integrated into the social philosophy of Jürgen Habermas.

SCIACCA, MICHELE FEDERICO (1908–1975)

Michele Federico Sciacca was a founder of the Gallarate movement, professor of theoretical philosophy at the University of Genoa, and the founder and editor of the journals *Giornale di metafisica* and *Humanitas*. He started as a historian of ideas, writing important works on Reid (1935), Plato (1939), and St. Augustine (1939); a massive review of Italian thought, *Il XX secolo* (2 vols., Milan, 1941); and a review of contemporary European thought, *La filosofia oggi* (Milan, 1945).

Although Sciacca studied under Antonio Aliotta, his major stimulus came from Giovanni Gentile, from whom Sciacca derived his basic axiom that concrete being must be act, never fact. Sciacca developed this principle in his own fashion under the influence of Plato, St. Augustine, Antonio Rosmini-Serbati, and Maurice Blondel.

Sciacca's position was one of "integralism." The central notion of integralism is interiority, according to which the ground of all forms of being and existence lies in the activity of the subject. Sciacca asserts that the existent, or act, cannot be a fact among facts; its existence resides wholly in its own self-generative actuality. Against existentialism he asserts that the being of the existent cannot be pure possibility or nothingness; it must be being. The whole concern of integralism is to establish the character of the being that the existent is. Sciacca holds this being to be objective interiority, which he delineates in his most original speculative work, *Interiorità oggettiva* (Milan, 1951). Interiority is the positing by the existent of itself as act. So defined, it cannot be conceived as purely immanent, in the manner of Gentile. It must posit itself with reference to a transcendent and objective reality and define itself within this horizon. The basic structural principle of interiority is truth, or the subject's affirmation of the ground of its existence in the very act of existing. The immanent ground of the subject and of all

existence is a transcendent being, not abstract but more concrete and existentially real than the subject—God. In affirming the existence of God, the subject also affirms its own being, the innermost character of its own act of existing.

Sciacca's basic insight is thus that the being of the subject cannot be mere possibility, nothingness, or facticity but must be act; that this act is the affirmation of its own actuality through the affirmation of its transcendent ground; and that the absolute existent is present in concrete human existence. It is this presence of the Absolute that establishes the human existent as a person. In *Morte ed immortalità* (Brescia, 1954), Sciacca holds that the affirmation of God within human existence that constitutes the human subject cannot be a merely transitory relationship and that immortality is therefore the logical extension of interior objectivity.

SCIENCE, RESEARCH ETHICS OF

The idea that ethics is important in scientific research is not new. In 1830 Charles Babbage (1791–1871) admonished British scientists for engaging in dishonest research. In 1912 researchers discovered the fossil skull of a missing link between humans and apes at the Piltdown quarry in Sussex, England. After four decades of controversy, several scientists proved that the skull was a hoax.

At the beginning of World War II, prominent physicists believed that it was their moral obligation to help defeat Nazi Germany. Albert Einstein wrote a letter to President Franklin D. Roosevelt (1882–1945) urging the United States to develop the atomic bomb. J. Robert Oppenheimer (1904–1967) directed the Manhattan Project, a \$1 billion effort to build the first nuclear weapons. After the United States dropped two bombs on Japan in the summer of 1945, many scientists who worked on the bomb also led the Atoms for Peace movement, which helped to establish the International Atomic Energy Commission. During the Nuremberg Trials (1949–1949), the international community adopted a code of conduct for human experimentation, the Nuremberg Code (1947), in response to the horrific experiments on human subjects conducted by Nazi researchers at Nuremberg.

In 1961 Rachel Louise Carson (1907–1964) alerted the public to the toxic effects of the pesticide DDT on animal species and helped to launch the environmentalist movement. In 1966, Henry Knowles Beecher (1904–1976) published an article describing twenty-two ethically problematic medical experiments, including the Tuskegee Syphilis Study. In this experiment, which took place from 1932 to 1972 in Tuskegee, Alabama, researchers withheld medical treatment from African American subjects with advanced syphilis, even after an effective treatment, penicillin, became available in the 1940s. The study continued until the media brought it to the public's attention in 1972, prompting Congress to hold hearings on biomedical research and adopt new laws pertaining to research on human subjects. In 1975, philosopher Peter Singer published a book that challenged the moral legitimacy of most experiments on animals and helped to energize the growing animal rights

movement. In that same year scientists held a conference at Asilomar, California, on the risks of genetically engineered microorganisms.

Interest in the ethics of research increased dramatically in the mid-1980s due to at least two factors. First, there were many highly publicized allegations of data fabrication (making up data), falsification (changing data), and other unethical activities in federally funded research. Second, the academic research enterprise became much more commercialized due to changes in intellectual property laws and the expansion of the pharmaceutical and biotechnology industries. In the 1980s, patent offices began awarding patents on many different biological products and processes, such as DNA, cell lines, and genetically modified organisms. The U.S. Congress also passed several laws encouraging the transfer of technology from the public to the private sector. In response to these changes in the law, universities began aggressively pursuing and protecting intellectual property. Academic researchers also took a greater interest in intellectual property and in forming start-up companies to commercialize new inventions and discoveries. The pharmaceutical industry increased its spending on research and development, and the biotechnology industry, which emerged in the late 1970s following the development of gene sequencing, splicing, and copying techniques, did the same. By the beginning of the twenty-first century, private industry accounted for more than sixty percent of all research and development expenditures in the United States.

As research became more commercialized, financial ties between academic and government scientists and private companies, for example, ownership of stock or patents and gifts or consulting arrangements, increased. These financial interests created a conflict of loyalties for scientists and universities and threatened the objectivity and trustworthiness of research. Scientists, ethicists, and journalists presented evidence that some researchers and private companies were biasing data analysis and interpretation, research design, and publication practices to produce results favorable to those companies. Financial interests (and pressures) in research also were linked to fabrication, falsification, and other ethical problems.

From the late-1980s to the early twenty-first century, many different organizations took steps to promote ethics in research. The National Institutes of Health (NIH) mandated that all students on Public Health Service training grants and all intramural researchers receive instruction in responsible conduct of research. Universities incorporated ethics education into the graduate cur-

riculum to meet NIH requirements and to minimize the risk of the legal liability and public embarrassment from ethical misconduct in research. The NIH and the National Science Foundation adopted a common definition of *research misconduct* as well as policies and procedures for investigating and adjudicating misconduct allegations. The National Academy of Sciences (NAS) published several reports concerning ethics in research. Many different professional organizations and scientific journals adopted or revised codes of conduct in research.

Research ethics has become multidisciplinary field of scholarship, education, and policy, encompassing the humanities, the social sciences, and the natural sciences. Some of the key topics in the field include: the foundations of research ethics; ethical decision-making in research; recording, storing, and sharing data; honesty and objectivity in research; scientific misconduct; authorship and publication; collaboration; mentoring; intellectual property; ownership of research materials; conflicts of interest; diversity in science; research on human and animal subjects; research in genetics and biotechnology; scientific freedom; social responsibility in research; research funding; and legal and regulatory aspects of research.

SCIENCE AND PSEUDOSCIENCE

Since the rise of modern science in the sixteenth and seventeenth centuries, attempts to adjudicate the difference between science and pseudoscience have always been more than an exercise in academic debate. The religious, political, and social implications of how science is defined, who defines it, and who and what is left out of the definition has been a contentious one. Today, the term *pseudoscience* is often employed by those in the scientific community to disparage claims to scientific credibility that, in fact, lack evidence or fail to employ the methods of science. *Pseudoscience* is only one term used to contrast with science; others include, on the neutral side, *non-science*, *protoscience*, *prescience*, *frontiers science*, and *borderlands science*; and on the pejorative side, *pathological science*, *junk science*, *voodoo science*, *crackpot science*, and *bad science*.

With the ascendancy of science in the seventeenth century other knowledge traditions began to employ the empirical methods of science to gain respectability. The study of demons, witches, and spirits, for example, took a decidedly empirical turn in the early modern period, out of religious concerns that atheism might ascend to social respectability along with science. One observer wrote, “Atheists abound in these days and witchcraft is called

into question. If neither possession nor witchcraft (contrary to what has been so long generally and confidently affirmed), why should we think that there are devils? If no devils, no God" (Walker, pp. 71–72). By the nineteenth century the study of such quasi-scientific ideas as phrenology, mesmerism, and spiritualism was organized through scientific societies, such as the Society for Psychical Research, founded in London in 1882, and the American Society for Psychical Research, founded in Boston in 1885, both of which included as active members prominent scientists.

THE DEMARCATION PROBLEM

In the twentieth century the philosophy of science developed into a viable academic discipline, out of which grew attempts to delimit science and nonscience traditions. In *The Logic of Scientific Discovery*, for example, the philosopher of science Karl Raimund Popper identified what he called "the problem of demarcation," that is "the problem of finding a criterion which would enable us to distinguish between the empirical sciences on the one hand, and mathematics and logic as well as 'metaphysical' systems on the other" (1934, p. 27). Most scientists and philosophers use induction as the criterion of demarcation—if one reasons from particular observations or singular statements to universal theories or general conclusions, then one is doing empirical science. Popper's thesis was that induction does not actually provide empirical proof—"no matter how many instances of white swans we may have observed, this does not justify the conclusion that all swans are white" (p. 34)—and that, de facto, scientists actually reason deductively, from the universal and general to the singular and particular. But in rejecting induction as the preferred (by others) criterion of demarcation between science and nonscience, Popper was concerned that his emphasis on deduction would lead to an inevitable fuzziness of the boundary line. If a scientific theory can never actually be proven, then is science no different from other knowledge disciplines?

Popper's solution to the problem of demarcation was the criterion of *falsifiability*. Theories are "never empirically verifiable," but if they are falsifiable then they belong in the domain of empirical science. "In other words: I shall not require of a scientific system that it shall be capable of being singled out, once and for all, in a positive sense; but I shall require that its logical form shall be such that it can be singled out, by means of empirical tests, in a negative sense: it must be possible for an empirical scientific system to be refuted by experience" (1934, p. 70).

The theory of evolution, for example, has been accused by creationists as being nonscientific because no one was there to see it happen and biologists cannot observe it in the laboratory because it takes too long. But, in fact, by Popper's criterion of falsifiability, the theory of evolution would be doomed to the trash heap of bad science if, say, human fossil remains turned up in the same geological bedding planes as 300-million-year-old trilobites. No such falsification of evolution has ever been found, and although by Popper's criterion this does not mean that the theory has been proven absolutely, it does mean that it has yet to be falsified, thus placing it firmly in the camp of solid empirical science.

SCIENCE DEFENDED, SCIENCE DEFINED

The evolution-creationism controversy, in fact, has provided both scientific and legal forms of demarcation between science and pseudoscience. It is one thing for academic scientists and philosophers to debate the definition of science; it is another matter when the U.S. Supreme Court weighs in on the issue. Because evolution could not be excluded from public school science classrooms in the early twentieth century, and because the teaching of religious tenets was deemed unconstitutional in a number of state trials in the middle of the twentieth century, in the latter part of the century creationists began to call their doctrines creation-science. Since academic openness calls for a balanced treatment of competing ideas, they argued, creation-science should be taught side by side with evolution-science. In 1982 creationists succeeded in getting passed the Louisiana Balanced Treatment for Creation-Science and Evolution Science Act. In 1985 the law was struck down in the Federal Court of Louisiana, a decision that was appealed to the U.S. Court of Appeals for the Fifth Circuit. In 1986 the U.S. Supreme Court agreed to hear the case, leading to the publication of a remarkable document that clearly and succinctly adjudicated (literally in this case) the difference between science and pseudoscience.

The document was an amicus curiae brief submitted to the court on behalf of seventy-two Nobel laureates in science, seventeen state academies of science, and seven other scientific organizations. The amicus brief begins by offering a general definition: "Science is devoted to formulating and testing naturalistic explanations for natural phenomena. It is a process for systematically collecting and recording data about the physical world, then categorizing and studying the collected data in an effort to infer the principles of nature that best explain the observed

phenomena.” Next, the scientific method is discussed, beginning with the collection of “facts,” the data of the world. “The grist for the mill of scientific inquiry is an ever increasing body of observations that give information about underlying ‘facts.’ Facts are the properties of natural phenomena. The scientific method involves the rigorous, methodical testing of principles that might present a naturalistic explanation for those facts” (1986, p. 23).

Based on well-established facts, testable hypotheses are formed. The process of testing “leads scientists to accord a special dignity to those hypotheses that accumulate substantial observational or experimental support.” This “special dignity” is called a “theory” that, when it “explains a large and diverse body of facts” is considered “robust” and if it “consistently predicts new phenomena that are subsequently observed” it is “reliable.” Facts and theories are not to be used interchangeably or in relation to one another as more or less true. Facts are the world’s data. Theories are explanatory ideas about those facts. “An explanatory principle is not to be confused with the data it seeks to explain.” Constructs and other nontestable statements are not a part of science. “An explanatory principle that by its nature cannot be tested is outside the realm of science” (pp. 23–24).

It follows from the nature of scientific method that no explanatory principles in science are final. “Even the most robust and reliable theory ... is tentative. A scientific theory is forever subject to reexamination and—as in the case of Ptolemaic astronomy—may ultimately be rejected after centuries of viability.” Scientists encounter uncertainty as a regular and natural part of their work. “In an ideal world, every science course would include repeated reminders that each theory presented to explain our observations of the universe carries this qualification: ‘as far as we know now, from examining the evidence available to us today’” (1986, p. 24). Science also seeks only naturalistic explanations for phenomena. “Science is not equipped to evaluate supernatural explanations for our observations; without passing judgment on the truth or falsity of supernatural explanations, science leaves their consideration to the domain of religious faith” (p. 23). According to the amicus any body of knowledge accumulated within the guidelines previously described is considered scientific and suitable for public school science education; and any body of knowledge not accumulated within these guidelines is not considered scientific.

On June 19, 1987, the U.S. Supreme Court, by a vote of 7 to 2, held that the Louisiana Act “is facially invalid as violative of the Establishment Clause of the First Amend-

ment, because it lacks a clear secular purpose” and that “[t]he Act impermissibly endorses religion by advancing the religious belief that a supernatural being created humankind” (*Edwards v. Aguillard*, 1987). The Louisiana trial in general, and the amicus brief in particular, had the effect of temporarily galvanizing the scientific community into defining science as a body of knowledge accumulated through a particular scientific method, as defined by the leading members of the scientific community themselves. Science is as scientists do.

DELIMITING THE BOUNDARIES BETWEEN SCIENCE AND PSEUDOSCIENCE

Creation-science (and its most recent hybrid, intelligent design theory) is just one of many claims that most mainstream scientists reject as pseudoscience. But what about those claims to scientific knowledge that are not so obviously classified as pseudoscience? When encountering a claim, how can one determine whether it constitutes a legitimate assertion as scientific? What follows is a list of ten questions that get to the heart of delimiting the boundaries between science and pseudoscience:

- (1) How reliable is the source of the claim? All scientists make mistakes, but are the mistakes random, as one might expect from a normally reliable source, or are they directed toward supporting the claimants’ preferred beliefs? Scientists’ mistakes tend to be random; pseudoscientists’ mistakes tend to be directional.
- (2) Does this source often make similar claims? Pseudoscientists have a habit of going well beyond the facts, and so when individuals make many extraordinary claims, they may be more than iconoclasts. What one is looking for here is a pattern of fringe thinking that consistently ignores or distorts data.
- (3) Have the claims been verified by another source? Typically, pseudoscientists make statements that are unverified or are verified by a source within their own belief circle. One must ask who is checking the claims and even who is checking the checkers.
- (4) How does the claim fit with what is known about how the world works? An extraordinary claim must be placed in a larger context to see how it fits. When people claim that the pyramids and the Sphinx were built more than 10,000 years ago by an advanced race of humans, they are not pre-

senting any context for that earlier civilization. Where are its works of art, weapons, clothing, tools, and trash?

- (5) Has anyone made an effort to disprove the claim or has only confirmatory evidence been sought? This is the confirmation bias or the tendency to seek confirmatory evidence and reject or ignore disconfirmatory evidence. The confirmation bias is powerful and pervasive. This is why the scientific method, which emphasizes checking and rechecking, verification and replication, and especially attempts to falsify a claim, is critical.
- (6) Does the preponderance of evidence converge on the claimant's conclusion or a different one? The theory of evolution, for example, is proved through a convergence of evidence from a number of independent lines of inquiry. No single fossil or piece of biological or paleontological evidence has the word *evolution* written on it; instead, there is a convergence from tens of thousands of evidentiary bits that adds up to a story of the evolution of life. Creationists conveniently ignore this convergence, focusing instead on trivial anomalies or currently unexplained phenomena in the history of life.
- (7) Is the claimant employing the accepted rules of reason and tools of research or have those rules and tools been abandoned in favor of others that lead to the desired conclusion? UFOlogists exhibit this fallacy in their continued focus on a handful of unexplained atmospheric anomalies and visual misperceptions by eyewitnesses while ignoring that the vast majority of UFO sightings are fully explicable.
- (8) Has the claimant provided a different explanation for the observed phenomena or is it strictly a matter of denying the existing explanation? This is a classic debate strategy: Criticize your opponent and never affirm what you believe to avoid criticism. This strategy is unacceptable in science.
- (9) If the claimant has proffered a new explanation, does it account for as many phenomena as does the old explanation? For a new theory to displace an old theory, it must explain what the old theory did and then some.
- (10) Do the claimants' personal beliefs and biases drive the conclusions or vice versa? All scientists have social, political, and ideological beliefs that potentially could slant their interpretations of the data,

but at some point, usually during the peer-review system, those biases and beliefs are rooted out or the paper or book is rejected for publication.

THE ENCHANTED GLASS OF SCIENCE

At the dawn of the scientific revolution in the early seventeenth century, the English philosopher Francis Bacon sought to turn away from the scholastic tradition of logic and reason as the sole road to truth, as well as reject the Renaissance quest to restore the perfection of ancient Greek knowledge. In his 1620 work *Novum Organum* (New Tool, contrary to the opinion of Aristotle's *Organon*), Bacon portrayed science as humanity's savior that would inaugurate a restoration of all natural knowledge through a proper blend of observation and logic, data and theory. Bacon understood, however, that there are significant social and psychological barriers that interfere with one's understanding of the natural world, "For the mind of man is far from the nature of a clear and equal glass, wherein the beams of things should reflect according to their true incidence; nay, it is rather like an enchanted glass, full of superstition and imposture, if it be not delivered and reduced" (p. 53). In the end, thought Bacon, science offers the best hope to deliver the mind from such superstition and imposture. Today, science continues to deliver on that hope.

SCIENCE POLICY

Science policy deals with how society supports science and how science is utilized in society. The philosophy of science policy considers both interactions from the perspectives of logic, epistemology, ethics, political philosophy, metaphysics, and ontology. Its domain is broader than the philosophy of science, which emphasizes logical and epistemological questions and goes deeper than the descriptive analyses of science, technology, and society (STS) studies.

The central issues in the philosophy of science policy may be distinguished in terms of its two constituent terms: the structure and proper influence of policy on science, and the structure and proper role of science in public policy. Propaedeutic is the question of the nature of policy itself.

WHAT ARE POLICIES?

What is known as the demarcation problem in the philosophy of science analyzes science as a special form of knowledge. What are known as boundary issues in STS studies describe the distinctive practices of the science-society interface. By contrast, the phenomenon of policy has been subject to little conceptual examination either as knowledge or as practice.

The term *policy* does not occur in traditional political philosophy. There is no word in either Plato's *Republic* or Aristotle's *Politics* that translates as *policy*. Neither

does it occur in Thomas Hobbes's *Leviathan* (1651) or Jean-Jacques Rousseau's *Social Contract* (1762). Indeed, the term is somewhat peculiar to the English language. *Policy* is translated into French as *politique* and into Spanish, depending on context, as *politica* or *norma*. In German it can be rendered by *Politik* and a host of other terms.

In English policies are associated with legal documents such as insurance contracts and guidelines for corporate or governmental behavior. Corporations have policies for the treatment of customers or employees, and governments and government agencies debate military, fiscal, educational, healthcare, and environmental policies. Although a policy has sometimes been defined simply as a decision, this seems inadequate if for no other reason than that one can talk about "policy decisions" and "decision policies."

Reframing Ludwig Wittgenstein's famous question, one may ask what is the difference between my arm going up, me raising my arm (*Philosophical Investigations* §161)—and a policy for raising my arm. The comparison suggests the concept of policy as a guideline for action justified by some kind of analysis. Policies fall in a middle range between decisions about individual actions and general principles for actions. Policies are also to be distinguished from laws and rules.

Since the key difference between my hand going up and me raising my hand is the presence of an intention, a policy might be seen as a particular kind of intention. G. E. M. Anscombe (1957) maintains that for a person to have an intention is to have both a desire to do X and a belief that he or she will do X. On this account intention becomes a secondary rather than a primary phenomenon. In like manner, policies would become secondary phenomena, derivative of desires and beliefs, with the beliefs being justified by scientific evidence or analysis that X will provide results satisfying the desire.

Anscombe's view is criticized by Donald Davidson (1978) and Michael E. Bratman (1987). Davidson believes that intentions are best described as pro-attitudes or evaluative judgments. According to Bratman the most effective way for human beings living in association with others to become effective agents is to have plans, the elements of which are intentions. For Davidson, then, policies might be defined as group pro-attitudes regarding types of actions. For Bratman policies would be closely associated with group plans.

The field of policy studies forms part of a general twentieth-century effort to extend scientific rationality

into group planning, especially in institutional contexts. (Having or making policies applies more to groups of people than to individuals, except for individuals in positions of power who set policies for others.) In this sense all policy is science policy, since it commonly involves scientific justifications of action plans, whether these are for military, fiscal, educational, healthcare, or environmental contexts.

POLICIES FOR SCIENCE

Following Harvey Brooks (1968), the philosophy of science policy explores two domains: the philosophical aspects of (1) policies for the funding and governance of science, and (2) ways that science can contribute to and/or impede the political process.

For fifty years after World War II, the basic principle underlying U.S. policy for science was that the government should provide no-strings attached funding to scientists, on the grounds that autonomous scientific research invariably benefits society by making contributions to military power, healthcare, and economic competitiveness further down the road (Bush 1945). There were arguments around the margins regarding how much independence to give scientists (e.g., national security required some limits) and about what constituted a well-balanced investment in mathematics, physics, chemistry, biology, and the social sciences. But no debate altered the basic policy: Give money to scientists and let them make their own decisions about how to spend it, because this will eventually rebound to the good of society.

The end of the cold war and increasing budget pressures allowed questions to surface about this basic policy and its foundational justification, the linearity thesis—the belief that autonomous scientific research produces social benefits in an automatic and linear way: more science, more benefit. As historical and sociological analyses of science have shown, however, the linearity thesis applies more to a few highly qualified special cases than as a general rule.

Reassessment of this policy approach has taken multiple forms. In one instance, in response to cases of research misconduct, it has been argued that conscious efforts are needed to promote collaboration between scientists and stakeholders (Guston 2000). Others have asked whether additional knowledge may overwhelm, getting in the way of the reflection needed about alternatives (Mitcham and Frodeman 2002). More generally, STS studies have argued the sociopolitical construction of scientific knowledge, thus challenging the ideal of scientific autonomy.

Taking these reassessments in a political philosophical direction, Philip Kitcher (2001) argues for a modification of linearity policy. Although a moderate realist who sees scientific knowledge as true, Kitcher is not willing to accept existing institutional arrangements for science as the best imaginable. Moreover, given the limitations of public funding, any one scientific research program is necessarily pursued at the expense of others, so that there is a proper place for extrascientific influence on the selection of publicly funded research priorities. Creating the proper policy for science depends on an understanding of what constitutes “well-ordered science” under such conditions.

SCIENCE IN POLICY MAKING

Several positions have been staked out in terms of how science properly contributes to policy making. In many quarters (both scientific and nonscientific) there has been a strong presumption that science can “answer” policy questions with the definitive account and/or solution to a problem. Although most policy analysts and many scientists now reject any simple version of this belief, it continues to influence the policy-making process. Two basic issues here concern the extent to which science can serve as an assessor or provider of means for nonscientifically determined ends, and whether or not science can assess ends as well as means.

The advancement of external ends has been a vision of modern science since its origins in the work of Francis Bacon, Galileo Galilei, and René Descartes. However, there has been little systematic examination of assumptions about whether in particular cases science is the best way to achieve certain goals. Does increased scientific knowledge or enhanced technologically efficient action always promote social or personal goods? Information overload can, for instance, actually inhibit decision making, and the excitements of technology have been known to skew appreciation of other goods.

At the end of the twentieth century a cadre of scientists and social scientists began to argue that science policy should go beyond the assumption of linearity. Daniel Sarewitz (1996), Donald E. Stokes (1997), and others proposed to examine the publicly stated goals of science funding and then scrutinize whether end-benefit outcomes have been or are likely to be achieved. While this new science policy is a substantial improvement over the old, it nevertheless limps in one important respect: It accepts whatever social goals may have been given a rhetorical blessing by the existing body politic. The philosophical analysis of methods for assessing connections

between scientific effort and assumed end-benefits deserves attention, but it does not reconsider the worthiness of the proposed ends themselves. Ends must be reflected on as well as means—which is where philosophy has a significant role to play.

The most philosophically expansive approach to policy research is what Harold D. Lasswell called the *policy sciences*. In the course of his long, interdisciplinary career, Lasswell sought to develop a method for the systematic analysis of any policy problem (see Lerner and Lasswell 1951, Lasswell 1971). Influenced by the Chicago school pragmatism of such thinkers as George Herbert Mead and Charles E. Merriam, Lasswell’s method centers around five intellectual tasks: clarification of goals; descriptions of trends; analysis of conditions; projection of future developments; and invention, evaluation, and selection of alternatives. These tasks are necessary to address intelligently any number of policy issues, whether public or private, from those associated with taxation or warfare to problems of manufacturing and marketing.

Despite Lasswell’s achievements, however, there are evident opportunities for further philosophical criticism of method in the policy sciences, the practice of which depends on a prior commitment to goods such as human rights and democracy. Illustrations of deeper reflections on ends can be found in such diverse work as Daniel Callahan (2003); Alan Lightman, Daniel Sarewitz, and Christina Desser (2003); and Leon Kass et al. (2003). Callahan questions what he calls the *research imperative* that seems to take every social problem as an opportunity for more scientific research. Lightman, Sarewitz, and Desser undertake a collective reflection on “living with the genie” of scientific and technological productivity. Kass and the President’s Council on Bioethics philosophically assess contemporary aspirations to turn therapy into enhancement.

PHILOSOPHICAL CRITICISM

In what sense is philosophy of science policy genuine philosophy? Philosophy may be subdivided along two major axes. The first axis is defined by the fundamental questions that constitute philosophical reflection, of which it is common to distinguish at least logic, epistemology, ethics, political philosophy, and metaphysics or ontology. A second axis is constituted by the particular fields or *topoi* where such questions are deployed. This axis yields an indefinite series of regionalizations such as the philosophy of science, of art, of religion, of law, of language, and more. The philosophy of science is characterized by the prominence of logical and epistemological issues, with

only subsidiary attention to ethics, political philosophy, or metaphysics. But, in fact, there are also important questions of the logic of science policy arguments, the character of science policy knowledge, the ethics of science policy decision making, and the political philosophy of science. Because every science policy makes assumptions about the status of science itself, the philosophy of science policy must consider not just the epistemological status of scientific knowledge but also the justice and ontological boundaries of science as a human activity and of its various institutions.

As a regional expression of philosophy, the philosophy of science policy explores a spectrum of concerns. Policy methods deserve logical analysis. The epistemological strengths and weaknesses of models and simulations, not just in physics or climatology but also in policy analysis, call for critical reflection. Behaviors within the professional scientific community and in relations between scientists and the public, including those of policy analysts, require philosophical assessment. Policies in and for scientific communities and those mediating between science and society, along with the role of scientific expertise in a democratic state, are subject to political philosophical scrutiny. Questions related to scientific institutions and their manifold boundary organizations are ontological as well as sociological; the distinction between policy for science and science in policy may be less sound than is commonly assumed.

Discussions that move from interest group power and economic efficiency to questions of truth, goodness, and beauty can make science policy work richer and more robust—and thus, in other than technical or economic senses, more effective. The philosophy of science policy holds out the promise of promoting science policies that are less incomplete, distorted, and unconscious than might otherwise be the case.

SCIENCE STUDIES

The phrase "science studies" is sometimes used as an umbrella term referring to work in history of science, philosophy of science, research ethics, and so on. But it can also designate a new interdisciplinary approach to the study of science, technology, and society, one that challenges traditional views about the epistemic basis of scientific knowledge and the proper role of science in society. It is this intellectual movement called Science and Technology Studies (STS) that will be discussed here.

Science Studies in the STS sense discards almost all of the distinctions common in traditional philosophy of science, such as the demarcation between the context of discovery and the context of justification, prescriptions versus descriptions, and theory versus observation. Instead, it looks at science as a social activity that cannot be usefully understood in isolation from either technology or society at large. More important than analysis is contextualization. Case studies of local scientific practices are the preferred route to understanding.

What we now call Science Studies (or STS) has a surprising variety of geographical roots. The Strong Program began in Edinburgh in the 1970s. Harry Collins's study of the experimenters' regress was done in England, where Steve Woolgar is also located. Bruno Latour's actor-network theory was developed in Paris. Karin Knorr Cetina worked in Bielefeld, Germany. Feminist standpoint epistemology stems from Sandra Harding's work in America. The 1980s saw a plethora of influential books and articles centered on the notion of social construction, some of it directly influenced by the pioneers such as that of Andrew Pickering, who earned his PhD at Edinburgh, and Trevor Pinch, who worked with Harry Collins at Bath. Systematic criticism of both the historical work and the philosophical claims of STS scholars resulted in the so-called Science Wars, which was triggered by a hard-hitting critical study in 1994 by Paul Gross and Norman Levitt.

Contributors to Science Studies (or STS) draw on resources from diverse disciplinary backgrounds, such as sociology, anthropology, political science, economics, and linguistics. But all the studies share starting points based on interpretations of work in more contemporary philosophy of science. It is to these common philosophical presuppositions that we now turn.

PHILOSOPHICAL ROOTS

Although Thomas Kuhn himself repudiated some of the most radical extensions of his theory of normal science and scientific revolutions, Science Studies is certainly part of his legacy. There are frequent STS references to his thesis that scientific knowledge is embodied in the practices of a community. Because observation is theory-laden, it is assumed that empirical studies can never be used as a neutral arbiter between rival paradigms. The logical fact that any universal theory is underdetermined by the evidence in support of it is taken to mean that there can be no rational basis sufficient to justify the choice of one theory over another. The point, noted by Pierre Duhem and W.V. Quine, that it is always logically possible to save a theory from refutation by altering auxiliary hypotheses is deployed to advance the skeptical conclusion that philosophical accounts of scientific method and scientific rationality cannot explain why scientists prefer some theories to others and assign great epistemic weight to certain claims and not to others.

Most philosophers of science in the early twenty-first century would agree that there is no ironclad defense against these kinds of skeptical arguments—indeed philosophers are the ones who undermined the quest for

unrevisable foundations in the first place! It is a truism today that there is no instant rationality in science. Instead, philosophers look for the fallible canons of comparative rationality that underlie scientific judgments. For example, in his theory of Scientific Research Programmes, Imre Lakatos argued that most of the history of science could be understood in terms of his methodology. It was only when the evaluations of actual scientists differed from his normative account that one should invoke extra-scientific considerations such as ideology, personal rivalries, or economic interests. Earlier historians of science also drew a distinction between internal history, a narrative of the mostly rational development of scientific ideas through the experimental method, and external history, the story of scientific institutions and their interaction with the larger society. And when sociologists such as Robert Merton studied those scientific institutions, they looked for the operation of special norms that would show why the output of science was superior to the knowledge produced by theologians or grocers!

Adherents to the Science Studies find little use for the internal or external distinction: Trying to isolate ideas from the people who hold them impedes understanding. Similarly, they would invert Lakatos's order of analysis. Instead of looking for the intellectual problems motivating researchers and their attempts to bring evidence to bear on proposed solutions, they begin with a rich sociological description of a scientific episode. What are the lines of authority and collaboration? Through what mechanism is expertise awarded? An important focus of the analysis should be the various rhetorical stratagems employed in communication: How do they reflect the conflicting interests or differing cognitive resources of the participants (for example, theoreticians versus experimenters, policy makers versus scientists, and funding committees versus referees)? The factors that philosophers of science or internalist historians find of interest would be embedded within the STS account, but they would never be privileged. Merton's norms of objectivity and organized skepticism are viewed primarily as part of the rhetorical arsenal of scientists, not as fundamental guides to behavior.

THE STRONG PROGRAM

Let us now take a brief look at some detailed proposals of the Science Studies approach, bearing in mind that there are disputes within this loosely-knit, interdisciplinary field. We begin with an early, very influential initiative—the Strong Programme of the Edinburgh school. David

Bloor describes the program as a sociology of scientific knowledge (SSK) that is based on four tenets.

First, our accounts of science should be causal (one is reminded of Marxian attempts to explain the content of scientific theories). Secondly, they should be impartial with respect to truth or falsity, rationality or irrationality—both are in need of explanation (many philosophical accounts take rational inference as self-explanatory—in fact to go further may lead to an infinite regress). Furthermore, the explanations of true and false beliefs should be symmetrical; that is, the types of causal factors invoked should be the same (if ideology or political interests are invoked to explain false beliefs, they also need to be brought into a story of the origins of true beliefs). Finally, our approach should be reflexive: The claims made from within the Strong Programme are to be analyzed and explained in exactly the same manner as are episodes in the history of science.

As laid out above, the Strong Programme is a variety of philosophical naturalism, a position that underlies most work in cognitive science. Its most controversial aspect is the symmetry thesis. Why should we posit a priori that the causal chain leading to hallucinations should contain exactly the same elements as the process that produces ordinary visual experiences? Or compare the stories of adherence of Soviet scientists to T. D. Lysenko's theory of acquired characteristics with that of the acceptance of Dmitri Mendeleev's Periodic Table in Czarist Russia: Undoubtedly both situations involved elements of nationalism and the striving of scientists for recognition. But are not the asymmetries more significant? In one case a major factor was the coercion to conform with the wishes of Joseph Stalin; in the other, chemists followed their noses to arrive at a workable classification of chemical phenomena.

Many of the case studies produced by adherents of the Strong Programme focus on scientific controversies. The general pattern is to look at a wide range of social factors, such as class, political pressures, disciplinary commitments, and power structures within the profession. They then argue that these kinds of interests have a strong influence on the conclusions that scientists reach about which of the competing theories is deserving of their allegiance. Their account of the resolution of a controversy does not privilege appeals to epistemic considerations such as predictive accuracy or theoretical coherence.

SOCIAL CONSTRUCTIONISM

Much work in Science Studies is based on the tenet that all scientific entities are socially constructed. In certain instances, such a claim is nontrivially true: John Searle uses the example of money. A metal disc with Sacagawea's portrait stamped on it does not count as money without the construction of a vast social network that turns it into legal tender. One can also make sense out of the assertion that there were no homosexuals until the late nineteenth century, by adding a gloss to the effect that the term homosexual is to be read as connoting a historically specific, medical-psychological category. But how are we to understand Latour's claim that there was no anthrax before Louis Pasteur's research or that TRH, a product of the hypothalamus, was invented in a certain California laboratory?

It is important to appreciate the difficulty scientists face in isolating natural products, especially when the process involves new sorts of instruments or laboratory procedures. But what is gained by blurring the distinction between a new concept, which certainly is a social construction, a chemical or biological entity, which either existed in nature or was synthesized, and the development of scientific consensus about the match between concept and the object described? It perhaps helps a little bit to understand why Latour and Woolgar would make such perplexing claims if we note that they set out to apply ethnographic approaches to life in the laboratory. Anthropologists who are studying an exotic culture dutifully describe the behavior of the people they are studying. An ethnomethodologist's thick description of a rain dance need say nothing about whether rain actually ensues. In a similar fashion STS scholars can describe the interactions and assertions of scientists without saying anything about whether the object the scientists claim to be studying actually exist. However, radical social constructionists go on to say that social constructions exhaust reality—there is no underlying strata that is being more or less accurately represented.

Even more startling is the so-called Actor-Network Theory (ANT) developed by Latour and Michel Callon, which posits a symmetry between humans and nonhuman entities, such as scallops (Callon's example) or technological devices. These so-called actants form networks in which their competing interests are negotiated. The result is a complex ecological system in which ideas and artifacts, scientist, and resources form an ontology based on what they call relational materiality. Difficult to understand, ANT has generated considerable critical discussion among STS practitioners. Some draw the line at

assigning agency to scallops; others object to attributing stability to inscription devices and the implication that scientific findings involving instruments can be exported from one lab to another without intervening social constructions by the local community.

FEMINIST STUDIES

A branch of Science Studies that has generated wide interest is the large corpus of feminist writings looking for the effect of gender ideology on both the content and practice of science. These range from significant, but relatively uncontroversial, empirical analyses of the social factors that lead to the attrition of women at every stage of their professional careers to radical claims about the intrinsically sexist nature of the science of mechanics. A central claim, and one that fits in well with some of the STS approaches described above, declares that scientific concepts of sex and gender have historically been strongly influenced by biases inherent in patriarchal societies. One recalls Aristotle's association of the active form with maleness, whereas females were the bearers of passive matter. Anne Fausto-Sterling argues that similar nonscientific influences have entered into the modern study of sex hormones. These are typical examples of social constructionist analyses: Scientific results are held to be strongly influenced by the social milieu; they are not simple reflections of empirical studies.

Feminists posit the influence of gender ideology on the content of science in areas increasingly distant from the study of reproduction. Londa Schiebinger claims that Carl Linneaus's characterization of the class mammalia was influenced by political debates about the propriety of wet nursing. Some have argued that the development of the science of hydrodynamics was delayed because men were uncomfortable dealing with material that was moist and yielding and that the interest in mechanical interactions between hard, rigid bodies that characterized the beginning of the Scientific Revolution was a masculinist preoccupation. And what about the scientific prejudice in favor of linear theories, reductionism, and simplicity? Relying on object-relations theory from psychology, it has even been claimed that the traditional norm of objectivity, of distancing oneself from phenomena, is a reflection of the process by which male children are psychically separated from the mother.

All of these studies follow the STS pattern of trying to show the radical contingency of scientific developments: If social circumstances had been different, the content of science would have been different. Feminists accompany this descriptive analysis with prescriptions for

changing science. Sandra Harding calls for what she calls strong objectivity: If present science is distorted by the predominance of male perspectives, would not science become more objective by the deliberate inclusion of views from the standpoint of women, minorities, workers, and any other group that is underrepresented in today's scientific community? Helen Longino advocates a sort of affirmative action for approaches to understanding the world that are anti-reductionist, nonhierarchical, and unabashedly politically progressive. If science is always socially constructed anyway, why not deliberately construct scientific inquiry in a humanitarian fashion?

REACTIONS TO SCIENCE STUDIES

The above descriptions of the leading STS approaches give an indication of why their underlying philosophical posits might be viewed as tendentious. Many of their case studies of the factors affecting the acceptance of scientific theories have also generated historiographic skepticism. Critics argue that, contrary to STS claims, Pasteur's religious views, Robert Boyle's preoccupation with chastity, or Karl Pearson's upwardly mobile class interests had a negligible effect on their scientific positions. As an explanation of the acceptance or rejections of scientific hypotheses, STS accounts are not satisfactory.

Ironically, however, the academic reaction to work in Science Studies cannot be understood purely in terms of its intellectual merits—or demerits. Instead, we must also invoke the sorts of interests and ideological factors that STS brings to the forefront! Members of the so-called academic left found the rhetoric of STS very congenial. Already suspicious of the authority of science and troubled by the pace of technological change, they eagerly took up slogans to the effect that science was a creature of the military-industrial complex and a handmaiden to imperialist regimes. The title of a popular textbook by Harry Collins and Trevor Pinch sums it up nicely: *Science as Golem*. There were calls for science for the people, feminist science, and postcolonial science.

Scientists and other intellectuals concerned about the level of funding for scientific research and the general low level of scientific literacy in America mounted a vigorous response. Paul Gross and Norman Levitt's *Higher Superstition: The Academic Left and Its Quarrels with Science* set off intense debates both in the media and in universities. Science Studies practitioners were sometimes lumped in with postmodernists, new age mystics, and so-called scientific creationists. Although STS people sometimes protested that they were not antisience per se, but only objecting to what they considered to be overly adu-

latory accounts of science as a hyperrational activity, they did not make a concerted effort to disassociate themselves from their more radical fellow travelers. Some critics took their ambivalent response to a hoax perpetrated by Alan Sokal, who succeeded in publishing a factually absurd, but politically correct, paper in a leading journal called *Social Text*, as an indication of a weak commitment to traditional scholarly norms.

Science Studies in the STS sense has spurred the attempts of historians, philosophers, and sociologists of science, who favor more traditional approaches to science studies, to provide accounts of the development of science that give us more understanding of the social dimensions of scientific inquiry (see Philip Kitcher's calls for a new socio-historico-philosophical approach). It has also highlighted the importance of developing a more detailed and realistic picture of scientific inquiry. This project is nicely described in the title of Susan Haack's book: *Defending Science—Within Reason: Between Scientism and Cynicism*.

Noretta Koertge (2005)

SCIENTIA MEDIA AND MOLINISM

The *scientia media* is a key term in the theology of Luis de Molina (1535–1600) and in the variants of his teaching introduced by the later Jesuits, especially Robert Bellarmine, Leonard Lessius, Francisco Suárez, and Gabriel Vasquez, in the attempt to resolve the apparent contradiction between the doctrines of grace and of free will.

Molina, a Spanish Jesuit who taught at Coimbra and Evora in Portugal, published his famous *Liberi Arbitrii cum Gratiae Donis, Divina Praescientia, Providentia, Praedestinatione et Reprobatione Concordia* at Lisbon in

1588. The publication of the *Concordia*, as it came to be called, soon led to a controversy that divided the theologians and philosophers of Spain. Generally, the position of Molina was enthusiastically supported by members of his own order and just as vigorously denounced by the Thomists.

For Molina the essential problem was to maintain both human freedom and the efficacy of grace. Given the fact of God's foreknowledge, Molina wished to preserve such a foreknowledge without lapsing into determinism, to show that although God knows infallibly what an individual will freely do, such an infallible knowledge in no way determines the will of the individual. Molina argued that there is a cooperation or concursus of human free will with the divine grace, in contrast to the Thomist view that man's will was physically predetermined to act freely by God. Molina held that this was only a disguised form of determinism. The Thomists maintained that Molina denied the universal divine causality.

The central point in Molina's solution of this problem is based upon the *scientia media*. This, according to Molina, is a form of the divine knowledge that lies between the two forms of God's knowledge that Thomas Aquinas had described in the *Summa*. Thomas maintained that God's knowledge may be one of "vision," a knowledge of that which exists, has existed, or will exist. Alternatively, God's knowledge may consist of the purely possible, a knowledge of "simple understanding," of things and events that have not existed, do not exist, and will not exist. The *scientia media* for Molina is a mean between these two forms of knowledge and is the knowledge that God has of conditional future contingent events; thus, God foreknows from all eternity what an individual would do under certain circumstances if offered his grace. Thomas held that nothing lies outside the divine causality and that God's knowledge, or vision, of the future free acts of the individual entails an act of will by God that predetermines that our acts are free. Molina insisted that God's knowledge is prior to the decree of his will and that his foreknowledge does not predetermine our free acts. God, knowing infallibly what an individual will do under certain circumstances if offered his grace, decrees the circumstances and the grace necessary to effect the cooperative action of the individual. Hence, the infallibility and efficacy of grace is due to the infallibility of God's knowledge, the *scientia media*, not to anything in the grace itself.

The distinction between sufficient and efficacious grace throws further light on these contrasting positions. Like the Thomists, Molina accepted the necessity of grace

for salvation, the absolute gratuity of grace, and that sufficient grace is given to all people. However, Molina denied the need for any distinction between sufficient and efficacious grace. He claimed that sufficient grace becomes efficacious if the will of the individual accepts it. Thus, God foreknew St. Paul's consent before he decreed the grace necessary for conversion. The concurrence of the simultaneous act of the individual and the grace of God replaced the notion that the decree of God is prior to the act of the individual and predetermines it. Thomists objected that this made the efficacy of the divine grace dependent on man rather than on God. Molina declared that the efficacy of grace was unimpaired, for its efficacy or infallibility was extrinsic to the act of the individual and intrinsic in God's foreknowledge. In effect, Molina endeavored to preserve more fully the freedom of the individual without destroying the power of grace; the Thomists were more concerned with preserving the power of grace without destroying the freedom of the individual.

LATER MOLINISM

Later Molinism is identified largely with what is termed *congruism*, a theological doctrine reflecting especially the views of Bellarmine and Suárez. Congruism retains the principal features of Molina's theology but modifies it in certain respects. Efficacious grace is equated with *gratia congrua* and sufficient grace with *gratia incongrua*. This distinction emphasized more strongly that grace was efficacious when it was congruous with those circumstances and the disposition of the individual that would enable him to will a certain act freely but infallibly. Grace was inefficacious when it was not congruous with the circumstances and disposition of the individual. The efficacy of the *gratia congrua* is intrinsic to the *scientia media* and extrinsic to the will of the individual. *Gratia incongrua* is grace that is sufficient for a salutary act but which the individual will reject.

On predestination the Molinists agreed with the Thomists that God wishes all people to be saved and that he extends sufficient grace to all, that contrary to Pelagianism predestination is wholly gratuitous, and that some individuals are elected in preference to others solely as God wills. However, they tended to modify the Thomist view of an absolute predestination to glory irrespective of foreseen merits. Many of the Molinists argued that predestination is conditional upon the future actions of the individual and becomes absolute only with the foreseen merits of the individual. In contrast to the Thomists, who argued for the priority of predestination

to glory to the predestination of efficacious grace, the Molinists held that God foresees in the *scientia media* that some will cooperate with his grace and predestined them to glory by offering them his grace.

The differences between Molina and his successors are more often subtle than essential. Although the debate on Molinism has continued for more than three centuries, Molinism is clearly compatible with faith and continues to have many supporters. Like Thomism it has its difficulties and its critics. The difference between the two schools remains essentially one of the relative emphasis to be placed upon grace or freedom.

SCIENTIFIC METHOD

What follows is a description of various views on inductive inference and methods for inferring general theories as they have developed from the scientific revolution to modern times. Later, the development of methods for discovering causal relationships will be discussed.

MODERN METHODOLOGY. A strong influence on contemporary methodology is interdisciplinary research. In

the twentieth century, the question of how we can use observations to attain empirical knowledge became the subject of research in a number of disciplines, such as statistics, econometrics, and computer science. Modern philosophy of method continues to contribute to and draw on developments in related disciplines.

Another strong influence on contemporary methodology arises from studies of the history of science, which captured the attention of philosophers because of the groundbreaking work of Thomas Kuhn (1922–1996) on the *Structure of Scientific Revolutions*. Kuhn argued that scientific textbook accounts of the history of science as a wholly progressive series of discoveries are false for scientific revolutions. His work has suggested that changes of method across revolutions undercut attempts to apply common standards to evaluate prerevolution and postrevolution theories.

Kuhn also criticized the methodological ideas of Karl Popper (1902–1994). Popper had asked the question of what distinguishes (“demarcates”) scientific hypotheses from nonscientific hypotheses. He emphasized that science proceeds by testing hypotheses against empirical data, and thus located the characteristic of scientific hypotheses in their empirical testability. Popper’s basic view of testing a hypothesis against data was to derive predictions from the hypothesis and see if they matched the data (conjectures and refutations). If the data does not match the predictions, they falsify the hypothesis.

This led Popper to postulate that scientific hypotheses must be falsifiable. Popper’s falsifiability criterion has been very influential, arguably more outside of the philosophy of science than inside. Kuhn objected to the falsifiability concept because, according to him, history shows that scientists do not subject major scientific theories (or paradigms) to falsification. Instead, scientists view a mismatch between theory and data as an anomaly, a puzzle to be resolved by further research. Many philosophers of science took Kuhn’s moral to be that logic-based analyses of scientific method cannot capture the dynamics of major scientific change. Scientific revolutions would instead be determined by complex sociopolitical processes within the scientific community, played out within the specific historical context. Modern methodologists aim to avoid both the extremes of a context-free universal scientific logic on the one hand, and an entirely context-specific study of particular historical episodes on the other.

METHOD IN THE SCIENTIFIC REVOLUTION

Two topics of inquiry held center stage during the scientific revolution: the traditional problems of astronomy, and the study of gravity as experienced by bodies in free fall near the surface of the earth. Johannes Kepler (1571–1630) proposed that the predictive empirical equivalence between geocentric and heliocentric world systems that holds in principle could be offset by appeal to physical causes (Jardine 1984). He endorsed the appeal by Nicolas Copernicus (1473–1543) to the advantage offered his system from agreeing measurements of parameters of the earth’s orbit from several retrograde motion phenomena of the other planets (1596/1981). In his classic marshaling of fit to the impressive body of naked eye instrument observation data by Tycho Brahe (1546–1601), Kepler appealed to this advantage as well as qualitative intuitions about plausible causal stories and intuitions about cosmic harmony to arrive at his ellipse and area rules (1609/1992). He later arrived at his harmonic rule (1619/1997). His Rudolphine Tables of 1627 were soon known to be far more accurate than any previously available astronomical tables (Wilson 1989).

Galileo Galilei (1564–1642) described his discovery of Jupiter’s moons and exciting new information about our moon in the celebrated report of his telescope observations (1610/1989). His later observations of phases of Venus provided direct observational evidence against Ptolemy’s system, though not against Tycho’s geoheliocentric system. This was included in his argument for a Copernican heliocentric system in his famously controversial *Dialogue* (1632/1967).

Galileo’s study of gravity faced the challenge that because of complicating factors such as air resistance one could not expect the kind of precise agreement with measurement that was available in astronomy. In his celebrated *Two New Sciences* (1638/1914), Galileo proposed uniformly accelerated fall as an exact account of idealized motion that would obtain in the absence of any resistant medium, even though the idealization is impossible to actually implement. He argues that the perturbing effects of resistance are too complex to be captured by any theory, but that the considerations he offers, including inclined plane experiments that minimize the effects of resistance, support his idealized uniformly accelerated motion as the principal mechanism of such terrestrial motion phenomena as free fall and projectile motion.

An important part of what distinguishes what we now characterize as the natural sciences is the method exemplified in the successful application of universal

gravity to the solar system. Isaac Newton (1642–1727) characterizes his laws of motion as accepted by mathematicians and confirmed by experiments of many kinds. He appeals to propositions inferred from them as resources to make motion phenomena measure centripetal forces. These give systematic dependencies that make the areal law for an orbit measure the centripetal direction of the force maintaining a body in that orbit, that make the harmonic law for a system of orbits about a common center, and that make the absence of orbital precession (not accounted for by perturbations) for any such orbit, measure the inverse square power for the centripetal force. His inferences to inverse-square forces toward Jupiter, Saturn, and the sun from orbits about them are inferences to inverse-square centripetal acceleration fields backed up by such measurements.

Newton's moon-test shows that the length of a seconds pendulum at the surface of the earth and the centripetal acceleration of the moon's orbit count as agreeing measurements of a single earth-centered inverse-square acceleration field. On this basis Newton identified the force maintaining the moon in orbit with terrestrial gravity. His first two rules endorse this inference. Rule number one states "no more causes of natural things should be admitted than are both true and sufficient to explain their phenomena" (Newton 1726/1999, p. 794). Rule number two adds that, therefore, "the causes assigned to natural effects of the same kind must be, so far as possible, the same" (Newton 1726/1999, p. 795).

Newton argues that all bodies gravitate toward each planet with weights proportional to their masses. He adduces a number of phenomena that give agreeing measurements of the equality of the ratios of weight to mass for bodies at equal distances from planets. These include terrestrial pendulum experiments and the moon-test for gravitation toward the earth, as well as the harmonic laws for orbits about them for gravitation toward Saturn, Jupiter, and the sun. They also include the agreement between the accelerations of Jupiter and its satellites toward the sun, as well as between those of Saturn and its satellites and those of the earth and its moon toward the sun.

His third rule endorses the inference that these all count as phenomena giving agreeing measurements of the equality of the ratios of weight to mass for all bodies at any equal distances from any planet whatsoever. Rule number three states that "those qualities of bodies that cannot be intended and remitted (i.e., qualities that cannot be increased and diminished) and that belong to all bodies on which experiments can be made should be

taken as qualities of all bodies universally" (Newton 1726/1999, p. 795).

Newton's fourth rule added that "In experimental philosophy propositions gathered from phenomena by induction should be considered either exactly or very nearly true notwithstanding any contrary hypothesis until yet other phenomena make such propositions either more exact or liable to exceptions" (Newton 1726/1999, p. 796). This rule was added to justify treating universal gravity as an established scientific fact, notwithstanding complaints that it was unintelligible in the absence of a causal explanation of how it results from mechanical action by contact.

Newton's inferences from phenomena exemplify an ideal of empirical success as convergent accurate measurement of a theory's parameters by the phenomena to be explained. In rule four, a mere hypothesis is an alternative that does not realize this ideal of empirical success sufficiently to count as a serious rival.

Rule four endorses provisional acceptance. Deviations count as higher order phenomena carrying information to be exploited. This method of successive corrections guided by theory mediated measurement led to increasingly precise specifications of solar system phenomena backed up by increasingly precise measurements of the masses of the interacting solar system bodies.

This notion of empirical success as accurate convergent theory mediated measurement of parameters by empirical phenomena clearly favors the theory of general relativity of Albert Einstein (1879–1955) over Newton's theory (Harper 1997). Moreover, the development and application of testing frameworks for general relativity are clear examples of successful scientific practice that continues to be guided by Newton's methodology (Harper 1997, Will 1986 and 1993). More recent data such as that provided by radar ranging to planets and lunar laser ranging provide increasingly precise post Newtonian corrections that have continued to increase the advantage over Newton's theory that Newton's methodology would assign to general relativity (Will 1993).

HYPOTHETICO-DEDUCTIVISM

In the preface to his *Treatise on Light*, Christian Huygens (1629–1695) provided a nice characterization of the hypothetico-deductive (H-D) alternative to Newton's method:

There will be seen in it demonstrations of those kinds which do not produce as great a certitude

as those of Geometry, and which even differ very much therefrom, since whereas the Geometers prove their Propositions by fixed and incontestable Principles, here the Principles are verified by the conclusions to be drawn from them; the nature of these things not allowing of this being done otherwise. It is always possible to attain thereby to a degree of probability which very often is scarcely less than complete proof. To wit, when those things which have been demonstrated by the Principles that have been assumed correspond perfectly to the phenomena which experiment has brought under observation; especially when there are a great number of them, and further, principally, when one can imagine and foresee new phenomena which ought to follow from the hypotheses which one employs, and when one finds that therein the fact corresponds to our prevision.

(HUYGENS 1690/1962, P. VI AND VII)

Thus H-D method construes empirical success as success in prediction. The limitation of empirical success to prediction alone has suggested to some philosophers of science that distinguishing between theories that agree on predictions would have to be based on nonempirical criteria.

PREDICTED FIT TO FUTURE DATA

Given plausible assumptions about errors in data, a model that fits a given body of data too closely is likely to be tracking random errors in the data in addition to the lawlike phenomenon under investigation. Statisticians refer to this as “overfitting the data.” They have designed many criteria to reveal cases where a simpler model has better expected fit-to-future data generated by repetitions of an experiment than a more complex model that better fits the data so far. Among philosophers of science, Malcolm Forster and Elliott Sober have appealed to the Akaike Information Criterion to challenge the assumption that fit-to-past data exhausts the criteria for scientific inference. This criterion is not sufficient to recover Newton’s method (Myrvold and Harper 2002). The extent to which other such proposals can recover Newton’s method is an open question.

BAYESIAN METHODS

Central to the Bayesian methods is epistemic probability, a rational agent’s degree of belief. A number of arguments have been put forward to defend the probability axioms

as coherence conditions for rational degrees of belief, in analogy to the way logical consistency can be taken as a coherence condition for rational acceptance. Dutch book arguments have shown that degrees of belief violating the probability axioms would assign positive expectations to each bet in a system of bets and conditional bets that would result in sure loss if they were all made together. A number of other arguments for this synchronic condition on rational degrees of belief have been advanced (particularly by Frank Plumpton Ramsey, Leonard J. Savage, Abner Shimony, Bas van Fraassen, Richard T. Cox, Irving John Good, and J. Aczel).

David Lewis (1941–2001) provided a diachronic Dutch book argument (published in Teller 1976) to defend the Bayesian conditionalization learning model, according to which assigning new degrees of belief given by $P'(B) = P(B \& A) / P(A)$ is the appropriate response to a learning experience in which the total relevant empirical input is to accept A as new evidence. In 1984 van Fraassen (1941–) extended this diachronic Dutch book argument to defend a condition he called reflection. His proposal to treat the reflection condition as a constraint on degrees of belief that could be counted as rational has led to much controversy.

One central Bayesian theme has been to investigate conditions under which evidence leads to convergence of opinion. Bruno de Finetti (1906–1985) specified conditions that would lead Bayesian agents, who update by repeated conditionization on the outcomes of the same observations, to converge toward agreement in their degrees of belief, however otherwise divergent their prior degrees of belief may have been (1937/1980). Brian Skyrms (1990) has given what is probably the most general possible version of de Finetti’s condition for convergence.

In 2003 Wayne Myrvold (1963–) argued that, for Bayesians, the degree to which a hypothesis unifies phenomena contributes to the degree to which these phenomena support the hypothesis. This suggests that Bayesians can recover important aspects of Newton’s method. It may well be that investigating the representation of Newton’s method of provisional acceptance in a Bayesian model will result in enriching the Bayesian framework to make it offer more resources for illuminating scientific method.

CAUSATION, CORRELATION, EXPERIMENTATION

In his famous methods (1843), John Stuart Mill (1806–1873) combined ideas about causal inference previously

proposed by John Duns Scotus (1265/66–1308), William Ockham (1280–1349) and Francis Bacon (1561–1626). The work of twentieth century statisticians such as Jerzy Neyman (1894–1981), Karl Pearson (1857–1936), and Ronald A. Fisher (1890–1962) addressed two major shortcomings of Mill's method.

First, Mill assumed that we would observe deterministic causal relationships: Given the cause, the effect must follow every time. However, in a complex situation we typically do not have a complete specification of all operative causes, so we expect to observe trends rather than necessary relationships. For example, although smoking causes lung cancer, it does not do so in every person, because people's physiology varies. Rather, what we observe is a strong association between smoking and lung cancer: Among smokers, the incidence of lung cancer is much higher than among nonsmokers. To define precisely the intuitive notion of "strong association," statisticians developed the concept of correlation, which defines degrees of association (DeGroot 1975).

A second deficiency in Mill's methods is that they fail in the presence of common causes (*confounders* in statistical terminology). For example, suppose we observe that children who play violent video games are more prone to aggressive behavior than children who do not. Mill's logic would lead us to infer that playing violent video games causes aggressive behavior. But another possibility is that the correlation is because of personality traits: that children with an aggressive nature are drawn to violent video games and tend toward aggressive behavior; a preference for violent video games does not cause the behavior, but is merely a symptom of preexisting aggressive tendencies. If this alternative explanation is true, then Mill's methods lead us to the wrong conclusion. The policy implications are significant: If there is a direct causal relationship between video games and aggressive behavior, we expect to reduce aggressive behavior by restricting the availability of video games. But if personality is the underlying common cause of both, restricting access to video games should not decrease aggressive behavior.

A great advance for the problem of unobserved common causes was Fisher's revolutionary idea of the randomized experiment. Suppose that we have the ability to randomly assign half of a group of children to playing violent video games (the treatment group) and the other half to playing something else (the control group). For example, we might flip a coin for each participating child to make the assignment. Then we expect that personality traits, such as a tendency to aggression, would be randomly distributed in each half so that the children play-

ing the video games would, on average, have no more aggressive personalities than the children playing something else. Under those circumstances, if we still find that significantly more of the video game players engage in aggressive behavior than the children playing something else, we can infer a direct causal relationship.

The idea of using randomization to rule out unobserved common causes has been applied in countless practical problems of causal inference, from clinical studies of the effectiveness of medical treatments to experiments for agricultural methods. It has been a most effective tool for addressing the problem of unobserved common causes that besets many of the traditional philosophical proposals for causal inference.

The power of randomization is available only when we have the ability to experimentally create the conditions we wish to investigate. In many settings of interest, we cannot perform experiments but can only passively gather data (these are called "observational studies" in statistics). A prominent physical science based on passive observation is astronomy. Many examples occur in the social sciences and economics. For instance, an economist cannot randomly assign inflation rates to various countries to study how inflation affects employment. A recent set of examples comes from computer science: While many companies gather vast amounts of data about their customers and the transactions they engage in, they rarely have the ability to assign customers randomly to various conditions (e.g., household income).

Philosophers continued to refine their understanding of the relationship between correlation and causation in nonexperimental settings. The work of Hans Reichenbach (1891–1953), published in 1956, was seminal. Reichenbach expounded the common cause principle: roughly, for every correlation between two events A and B, there is some causal explanation that posits either that one is a cause of the other (e.g., A causes B) or that A and B share a common cause. Reichenbach argued that the assumption that significant associations or correlations have causal explanations is deeply ingrained in our scientific and everyday reasoning. Another important concept of Reichenbach was the notion of screening off. The purpose of this concept is to capture the distinction between immediate and intermediate causes in terms of correlations.

For example, suppose that tar content in lungs is the direct cause of cancer, while smoking directly causes tar to accumulate in the lungs, and thereby indirectly causes lung cancer. Then we would observe a correlation between smoking and lung cancer; but knowing the tar

content of the lung would make smoking irrelevant to lung cancer. By contrast, even if we knew whether a subject smokes, the tar content of one's lungs would still be relevant to, or correlated with, the subject getting lung cancer. In Reichenbach's terms, information about tar content screens off information about smoking from conclusions about lung cancer. Because tar content screens off smoking from lung cancer, but not vice versa, Reichenbach suggested that such evidence rules out smoking as a direct cause of lung cancer, and allows us to infer that the effects of smoking are mediated through tar in the lungs.

The philosophers of science—Peter Spirtes, Clark Glymour, and Richard Scheines—developed Reichenbach's ideas about the relationships between correlation and causation using the framework of causal graphs or diagrams (Spirtes 1993). A causal graph is an intuitive representation of causal relationships, in which direct causes are connected with their effects by arrows pointing from cause to effect.

Using the language of causal graphs, Spirtes, Glymour, and Scheines gave a precise formulation of Reichenbach's precept that direct causes screen off indirect ones, known as the Markov condition (I-map in computer science terminology). The common cause principle—that there is no correlation without causation—can be formulated as another principle about diagrams, termed faithfulness (perfect I-map in computer science terminology). Given these principles relating causation and correlation, it is possible to characterize when valid inferences about causal relationships can be drawn from passive observation of associations. The theory is powerful and precise enough to develop computer programs that perform these inferences automatically (the TETRAD system, for instance). With such a program, we can analyze the kind of large datasets that we find in practice, realizing the vision of Bacon and Mill of applying causal inference methods to extensive observation histories.

In computer science, causal diagrams (often called Bayes Nets) have been firmly established as a scheme to capture and reason about associations and causal relationships, giving rise to thriving commercial developments with many practical applications (Pearl 1988, 2000). Econometrics, the study of statistical methods for economic problems, has a rich tradition of developing methods for nonexperimental causal inference going back to the early twentieth century (path diagrams and structural equation models). It turns out that many of these ideas and techniques can be seen as instances of

causal diagram methods (Pearl 2000). While the theory of causal inference from passive observation is not yet as firmly established as the methodology based on randomization, at the beginning of the twenty-first century we see a common framework emerging shared and sustained by philosophy, computer science, and economics.

Oliver Schulte (2005)

SCIENTIFIC REALISM

Scientific realism is a philosophical view about science that consists of three theses:

The metaphysical thesis: The world has a definite and mind-independent structure.

The semantic thesis: Scientific theories should be taken at face value. They are truth-conditioned descriptions of their intended domain, both observable and unobservable. Hence, they are capable of being true or false. The theoretical terms featured in theories have putative factual reference.

The epistemic thesis: Mature and predictively successful scientific theories are well confirmed and (approximately) true of the world. So the entities posited by them, or entities very similar to those posited, inhabit the world.

METAPHYSICS

Let us call the first thesis of scientific realism *metaphysical realism*. What exactly is involved in the claim of mind-independence? One way to construe the opposite claim that the world is mind-dependent, along the lines of traditional idealism and phenomenalism, is to argue that the world consists of mental entities, be they ideas or actual and possible sense-data. Thus understood, mind-dependence is a thesis about the kind of stuff that makes up the world. The insistence of scientific realism on metaphysical realism might be thought of as opposing this idealist or phenomenalist doctrine. It might be seen as a declaration that there is nonmental stuff in the world and, in particular, that the entities posited by scientific theories are material. This view is certainly part of the realist construal of mind-independence, but there is more.

There is another, more complicated and interesting, way to construe the claim that the world is mind-dependent. This way centers not on what *types* of entity exist (whether they are material or mental or what have you) but rather on what is involved in claiming that they *exist*. There is a long antirealist philosophical tradition according to which it does not make sense to assert the existence (or reality) of some entities unless we understand this assertion to mean that . . . , where the ellipsis is filled with a suitable epistemic/conceptual condition. Much like realism, these views (call them varieties of verificationist antirealism) oppose idealism and phenomenalism. They entail the position (or at least are consistent with the

claim) that material objects are real (be they the middle-sized entities of common sense or unobservable entities).

The substantive disagreement between this antirealist tradition and realism is the *sense* of existence. Verificationist antirealism makes the world (or a set of entities) mind-dependent in a more sophisticated sense: What there is in the world is determined by what can be known to exist (verified to exist, rationally accepted as existing, or the like). Hence it forges a logical-conceptual link between what there is in the world and what is affirmed as existing on the basis that it satisfies suitable epistemic conditions. Accordingly, the realist claim of mind-independence should be understood as logical or conceptual independence: What the world is like does not logically or conceptually depend on the epistemic means and conceptualizations used to get to know it. Scientific realism allows for the possibility of a *divergence* between what there is in the world and what is issued as existing by a suitable set of conceptualizations and epistemic conditions. Verificationist antirealism precludes this possibility of divergence a priori by advancing an epistemic conception of truth. No matter what the details of this conception are, the key idea is that truth is conceptually linked with epistemic conditions so tightly that a theory cannot be false even though epistemically justified (because it meets the relevant epistemic condition, for example, being under ideal circumstances theoretically justified or warrantably assertable). Typically, realists honor the possibility of divergence by adopting a non-epistemic conception of truth (the standard candidate for which is the correspondence theory of truth).

Why should scientific realism incorporate the claim of mind-independence? Why, that is, cannot someone who accepts the reality of unobservable entities but regards them as mind-dependent (in the above sense) be a scientific realist? Ultimately at stake in the debate over scientific realism is a robust sense of objectivity, that is, a conception of the world as the arbiter of our changing and evolving conceptualizations of it. Scientific realism honors this conception by claiming that the world is mind-independent. The kernel of its metaphysical thesis is that science is in the business of discovering what a world that is not of our making is like. This thesis implies that if the natural kinds posited by theories exist at all, they exist objectively, that is, independently of our ability to be in a position to know them, verify them, recognize them, etc., and hence that natural kinds, if anything, make scientific theories true. This robust sense of objectivity contradicts verificationist antirealism. It also blocks a number of projectivist or social constructivist views

about science from being realist. In the view of scientific realism, scientific theories and scientific theorizing in general, instead of projecting (or worse, socially constructing) the structure of the world, discover and map out an already structured, mind-independent world.

SEMANTICS

Let us call the second thesis of scientific realism, the view that scientific theories should be taken at face-value, *semantic realism*. This view too was motivated by problems with verificationism.

Verificationism, at least in its traditional form as defended by the logical positivists, runs together two separate issues: the evidential basis for the truth of an assertion and the semantic relation of reference or denotation. It thereby conflates the issue of what constitutes evidence for the truth of an assertion with the issue of what makes the assertion true. This conflation was the product of concerns about the meaning of theoretical terms. Some empiricists thought that since the meaning of theoretical terms is not given directly in experience, these terms are semantically suspect. Hence, empiricists (even hard-core positivists like Ernst Mach) sought to show that theoretical statements and terms are parasitic on observational statements and terms.

This line of thought led to *reductive empiricism*, which treats theoretical statements as being disguised talk about observables and their actual (and possible) behavior. Interestingly, this view is consistent with the claim that theoretical statements have truth-values, but it understands their truth-conditions reductively: Their truth-conditions can be fully captured in an observational vocabulary. Hence, theoretical statements are ontologically innocuous: They do not refer to unobservable entities, and so imply no commitments to unobservable entities. Despite the heroic efforts of many empiricists (including the early Rudolf Carnap), all attempts to translate theoretical terms into observational terms have patently failed. As a result, empiricism became liberal. It admitted that theoretical terms and statements have excess content that cannot be fully captured by any reference to observable entities and phenomena.

If evidence-conditions and truth-conditions are kept apart, verificationism loses its bite. Semantic realism, simply put, says that there should not be two semantic standards, one for observational statements and another for theoretical ones. Observational statements, as well as theoretical statements, are true if and only if their truth-conditions obtain. Hence, theoretical terms, no less than observational terms, have putative factual reference. If

theoretical statements cannot be given truth-conditions in an ontology that dispenses with theoretical entities, a full and just explication of scientific theories simply requires commitment to irreducible unobservable entities, no less than it requires commitment to observable entities.

Instrumentalism claims that theories should be seen as (useful) instruments for organizing, classifying, and predicting observable phenomena. So the “cash value” of scientific theories is fully captured by what theories say about the observable world. Faced with the semantic realist challenge that theoretical assertions are meaningful and purport to describe an unobservable reality, instrumentalism took refuge in Craig’s theorem and claimed that theoretical commitments in science are dispensable: Theoretical terms can be eliminated en bloc without loss in the deductive connections between the observable consequences of the theory. If this is so, then the very question of whether theoretical terms can refer to unobservable entities evaporates. This challenge led Carl Hempel (1958) to formulate what he called “the theoretician’s dilemma.” If the theoretical terms and the theoretical principles of a theory do not serve their purpose of a deductive systematization of the empirical consequences of a theory, then they are dispensable (unnecessary). But by Craig’s theorem, even if they do serve their purpose, they can still be dispensed with. Hence, the theoretical terms and principles of any theory are dispensable.

Is the theoretician’s dilemma compelling? Note first that the very idea of this dilemma rests on a sharp distinction between theoretical terms and observational ones. This dichotomy was severely challenged in the 1960s, when Pierre Duhem’s view that all observation is theory-laden resurfaced. Along with it came the view that, strictly speaking, there are no observational terms. But even if the dichotomy is accepted, instrumentalism based on Craig’s theorem collapses. It is implausible to think of theories as establishing only a deductive systematization of observable phenomena. Theories also offer inductive systematizations in the sense that theories can be used to establish inductive connections among observable phenomena: They function as premises in inductive arguments and, together with other premises concerning observable phenomena, yield conclusions that refer to observable phenomena. Seen as aiming to establish inductive connections among observables, theories are indispensable. There followed a battery of indispensability arguments, fostered by Sellars (1963) and Quine (1960) among others, suggesting that theoretical terms are indispensable in any attempt to formulate a powerful

and efficacious system of laws and to explain why observable entities obey the empirical laws they do.

Semantic realism opposes both instrumentalism and reductive empiricism. It renders scientific realism an “ontologically inflationary” view. Understood realistically, theories admit of a literal interpretation, that is, an interpretation according to which the world is populated by a host of unobservable entities and processes. Semantic realism is not contested any more. All sides of the debate take theoretical discourse to be irreducible and contentful. It should be clear from the above discussion, however, that making semantic realism the object of philosophical consensus was no trivial feat.

EPISTEMOLOGY

Let us call the third thesis of scientific realism *epistemic optimism*. Its thrust is that science can and does deliver theoretical truth no less than it can and does deliver observational truth. One can grant semantic (even metaphysical) realism and yet remain epistemically skeptical or agnostic toward scientific theories. This agnostic stance has appealed to empiricists who have come to terms with the collapse of instrumentalism and reductive empiricism. An argument for the realist interpretation of scientific theories is not ipso facto an argument for *believing* in the existence of the entities those theories posit and in the truth of what they say of them.

Can the epistemic thesis be avoided? Some realists, notably Alan Musgrave (1999), think that scientific realism is an exclusively axiological thesis: Science aims for true theories. There is clear motivation for this axiological approach: Even if *all* theories scientists ever came up with were false, scientific realism would not thereby be threatened. There are, however, inevitable philosophical worries about the axiological characterization of realism. First, it seems rather vacuous. Realism is rendered immune against the serious criticism stemming from the empirical claim that science has a poor record in tracking the truth. Second, aiming at a goal (truth) whose achievability by the scientific method is left unspecified makes the supposed regulative role of the goal totally mysterious. Finally, we lose all the excitement of the realist claim that science engages in a cognitive activity that pushes back the frontiers of ignorance and error. Other realists, notably Jarrett Leplin (1997), do take the epistemic thesis to be part of scientific realism, but argue for a minimal or thin version of it: There are possible empirical conditions that would warrant attributing some measure of truth to theories. The problem with this minimal account is that, in the end, it cannot provide a rational or warranted basis

for belief in the unobservable entities posited by science (and the assertions made about them).

Naturally, the scope of the epistemic thesis need not (and should not) be universal. Scientific realists need not take current science uncritically. They need not commit themselves to everything that current theories assert. They can have a differentiated attitude toward the theoretical constituents of modern science: Some of them are better supported by the evidence than others; some play an indispensable explanatory role, while others do not; some contribute to the successes of theories, while others do not. But we should not lose sight of the general philosophical issue at stake, which is this: Are there good reasons to believe that science cannot achieve theoretical truth? That is, are there good reasons to believe that, given that we understand the theoretical statements of scientific theories as genuine propositions, we can never be in a warranted position to claim that they are true (or at least, more likely true than false)? The *epistemic thesis* denies that there are such good reasons and defends the claim that the ampliative-abductive methods of science are reliable and can justify/support theoretical assertions. Hence, science has succeeded in tracking truth. To be sure, this success requires a certain amount of epistemic luck: It is not a priori true that science has been, or has to be, successful in truth tracking. If science does succeed in truth tracking, this is a radically contingent fact about how the world is and how science and its method have managed to latch onto it.

The prime argument in favor of the epistemic thesis has come to be known as “the no-miracles argument.” It is an abductive argument, or inference to the best explanation. Jack Smart (1963) argued against instrumentalists that they must believe in cosmic coincidence. On the instrumentalist view of theories, a vast number of ontologically disconnected observable phenomena are “connected” only by a purely instrumental theory: These phenomena just *happen* to be related to one another in the way suggested by the theory. Scientific realism, in contrast, leaves no space for a cosmic-scale coincidence: It is *because* theories are true and *because* the unobservable entities posited by them exist that the phenomena are related to one another as they are. Smart’s key point was that scientific realism (and its concomitant view of science) should be accepted because it offers the best explanation of why the observable phenomena are as scientific theories predict them to be.

Hilary Putnam (1975) and Richard Boyd (1973) argued that inference to the best explanation is the very method scientists use to form and justify their beliefs in

unobservable entities, and that realism should be seen as an overarching empirical hypothesis deriving support from the fact that it offers the best explanation of the success of science. The no-miracles argument found pithy expression in Putnam’s encapsulation: “The positive argument for realism is that it is the only philosophy that does not make the success of science a miracle” (1975, p. 73). A key element of the realists’ epistemic optimism comes from the fact that some theories, because they yield novel predictions, can serve as “prophets for us,” as Duhem put it. Only on a realist understanding do novel predictions about phenomena come as no surprise.

How exactly does the no-miracles argument support the epistemic thesis? Though this issue has been extensively debated, the role of the no-miracles argument in the realism debate is quite complex. To a good approximation, the argument should be seen as a grand inference to the best explanation. It is a philosophical argument that aims to defend the reliability of scientific methodology in producing approximately true theories. The argument proceeds in two steps. The first is that we accept as approximately true the theories that are implicated in the (best) explanation of the *instrumental* reliability of first-order scientific methodology. The second step is that since these theories have typically been arrived at by means of inference to the best explanation, such inference is reliable. The main strength of the no-miracles argument rests on the first part of the argument. Coming after more concrete types of explanatory reasoning that occur all the time in science, the argument suggests that it is reasonable to accept certain theories as approximately true, at least as concerns their components that guided predictions. These successful instances of explanatory reasoning in science provide the basis for the grand abductive argument. However, the no-miracles argument is not just a generalization over the scientists’ abductive inferences. Although itself an instance of the method that scientists employ, it aims at a much broader target, specifically, to defend the thesis that inference to the best explanation (a *type* of inferential method) is reliable. This relates to the second step of the argument. What makes the no-miracles argument distinctive as an argument for realism is that it defends the claim that theoretical truth is achievable. The second step of the argument seeks to secure this claim. It is reasonable to believe that abductive reasoning is reliable, since it tends to generate approximately true theories.

There are two challenges to scientific realism. The first relies on the claim that the evidence underdetermines theories and is discussed in a separate entry. The

second argument is the so-called pessimistic induction. As Larry Laudan (1984) pointed out in developing this argument, the history of science is replete with theories that were once considered empirically successful and fruitful but that turned out to be false and were abandoned. If the history of science is a wasteland of aborted best theoretical explanations of the evidence, then it might well be that current best explanatory theories will travel the route to this wasteland in due course. The best defense of realism against the pessimistic induction has been to try to reconcile the historical record with some form of realism. To do this, realists need to be more selective in what they are realists about.

A claim that emerged with some force in the 1990s is that theory-change is not as radical and discontinuous as the opponents of scientific realism have suggested. Realists such as Philip Kitcher (1993) and Stathis Psillos (1999) have sought to ferret out the theoretical components of abandoned scientific theories that essentially contributed to their successes, separate them from other idle components, and demonstrate that the components making essential contributions to the empirical success of the theories were retained in subsequent theories of the same domain. In such a scenario, the fact that our current best theories may be replaced by others does not necessarily undermine scientific realism. All that such evolution shows is that we cannot get at the truth all at once, and that our judgments from empirical support to approximate truth should be more refined and cautious in that they should commit us only to the theoretical components that enjoy evidential support and contribute to the empirical successes of the theory. Realists ground their epistemic optimism on the fact that newer theories incorporate many theoretical components of their superseded predecessors, especially those components that have led to empirical successes. The substantive continuity in theory-change suggests that a rather stable network of theoretical principles and explanatory hypotheses has emerged, survived revolutionary changes, and become part and parcel of our evolving scientific image of the world.

Faced with the challenge of the pessimistic induction, other realists have sought to weaken realism. There have been two prominent strategies for weakening realism. The first is to opt for structural realism, and the second is to opt for entity realism. Structural realism, defended by John Worrall (1989), capitalizes on the fact that despite the radical changes at the theoretical level, successor theories have tended to retain the *mathematical structure* of their predecessors. It argues that theories can

successfully represent the structure of the world even when they are wrong about the entities they posit. Despite its initial appeal, it turns out that this particular position is very difficult to defend. For one, the distinction between the mathematical structure of the theory and its theoretical content is not as clear-cut as it initially seems. For another, even if a sharp distinction is granted, it turns out that structural realism collapses the difference between the claim that a theory is true and the claim that it is empirically adequate.

Entity realism, defended by Nancy Cartwright (1983) and Ian Hacking (1983), accepts the existence of all sorts of unobservable entities but denies the truth of the theories in which descriptions of these entities are embedded. A major motivation for entity realism comes from laboratory life. Experimenters have good reasons to believe in specific unobservable entities, not because they accept the relevant theories, it is claimed, but rather because they *do* things with these entities. If these entities did not exist, the phenomena of the laboratory would be inexplicable. But can one be a realist about theoretical entities without also being a realist about the theories? In a sense, one can. For posited entities survive theory-change. For instance, scientists accept the existence of electrons even though their theoretical views about what electrons are have changed. So it appears that we can know *that* the electron is, even though we may not know *what* it is. But this cannot be fully right. We cannot assert that electrons are real, that is, that electrons are part and parcel of the furniture of the world, without also asserting that they have *some* of the properties attributed to them by our best scientific theories. So entity realism cannot be fully divorced from theory realism. In any case, the very same inferential process (inference to the best explanation) is involved in accepting the reality of an entity and in accepting the approximate correctness of some theoretical description of it.

SCIENTIFIC REALISM AND EMPIRICISM

Bas van Fraassen (1980) fostered a rivalry between scientific realism and empiricism with his influential doctrine of constructive empiricism. According to this view about science, (a) science aims at empirically adequate theories, and (b) acceptance of scientific theories involves belief only in their empirical adequacy (though acceptance involves more than just belief; it also involves commitment to the theory). Van Fraassen took realism to be, by and large, an *axiological* thesis: The aim of science is true theories. He supplemented it with a *doxastic* thesis:

Acceptance of theories implies belief in their truth. Seen in this way, realism and constructive empiricism are rivals. But, of course, a lot depends on whether an empiricist ought to be a *constructive* empiricist. There is no logical obstacle impeding an empiricist (who thinks that all knowledge ultimately stems from experience) from fostering methods that warrant belief in the truth of theories in a way that goes beyond belief in their empirical adequacy, and hence from being a scientific realist. Similarly, there is no logical obstacle impeding an empiricist from being stricter than constructive empiricism, for instance, by claiming that (a') the aim of science is unrefuted theories and (b') acceptance of a theory involves the belief only that it is unrefuted.

Constructive empiricism does set the boundaries of experience much farther afield than strict empiricism, and since what empiricism is, is not carved in stone, there is no logical obstacle to setting the boundaries of experience (that is, the reach of legitimate applications of scientific method) even farther afield, as realists demand. Indeed, as Hans Reichenbach (1938) noted, the key question is what kinds of methods are compatible with empiricism. Even if we grant, as we should, that all factual knowledge starts with experience, the boundaries of experience depend on the warrants of the methods employed. It is perfectly compatible with empiricism to accept ampliative methods and to accept the existence of unobservable entities on their basis. So there is no incompatibility between being an empiricist and being a scientific realist.

Van Fraassen tied empiricism to a sharp distinction between observable and unobservable *entities*. This, to be sure, is a step forward from the more traditional empiricist distinction between observational and theoretical terms and predicates. Drawing the distinction in terms of entities allows the description of observable entities to be fully theory-laden. Yet, van Fraassen insisted, even theoretically described, an entity does not cease to be observable if a suitably placed observer *could* perceive it with the naked eye.

Long before van Fraassen, Grover Maxwell (1962) denied this entity-based distinction, arguing that observability is a vague notion and that, in essence, *all* entities are observable under suitable circumstances. He based this view on the claim that "observability" is best understood as detectability by some means. If observability is thus understood, there are continuous degrees of observability, and hence there is no natural and nonarbitrary way to draw a line between observable and unobservable *entities*. Rebutting Maxwell's argument requires that

naked-eye observations (which are required to tell us which entities are *strictly* observable) form a special kind of detection qualitatively set apart from any other way of detecting the presence of an entity (for example, with a microscope). Be that as it may, the issue is not whether the distinction between observable and unobservable entities can be drawn but what its epistemic relevance is: Why should the observable/unobservable distinction define the border between what is epistemically accessible and what is not?

In the end, scientific realism is better than constructive empiricism because (1) it does not rely on a distinction of dubious epistemic significance, specifically, the observable/unobservable distinction, (2) it offers a better explanation of the empirical successes of science, and (3) it tallies better with actual scientific practice.

SCIENTIFIC REVOLUTIONS

Largely as the result of Thomas Kuhn's work, the concept of scientific revolution gains an importance in post-positivist philosophy of science that it lacks in the dominant logical empiricist tradition of the twentieth century. Kuhn's notion of scientific revolution becomes wedded to a historical relativism concerning scientific knowledge that many have sought to refute, or overcome with new accounts of knowledge that go beyond positivism and relativism.

THE CONCEPTION OF SCIENTIFIC REVOLUTION IN TRADITIONAL PHILOSOPHY OF SCIENCE

To set the context for these debates, it is useful to begin with the ordinary concept of scientific revolution and understand why it lacks fundamental epistemological significance in traditional philosophy of science. In ordinary parlance, a scientific revolution is a large-scale change in the fundamental concepts, theories, or methods that scientists in some area of inquiry employ to understand the course of nature (e.g., the Copernican revolution in astronomy). Such a change is also thought to be revolutionary in so far as it provokes similarly dramatic alterations in the way laypeople see the world. As such, the notion is obviously important to historians of science and popular culture. On the other hand, scientific revolution is not a central topic for the tradition of logical positivism (more broadly, logical empiricism) that generates the key figures, problems, and models of philosophy of science for most of the twentieth century.

In this tradition, the aim of philosophy of science is to provide analyses of the standards most vital to science

as the best exemplar of empirical knowledge: the standards of scientific method, confirmation, prediction, falsification, explanation, truth, progress, observation, law, and theory. The philosopher's analyses are supposed to be timeless, normative, universal, non-historical, and non-empirical. To this end, logical empiricists employed the tools of logic and semantics to illuminate the a priori formal structure of all genuine scientific knowledge (such as explanation and confirmation). Science is identified with its most successful theories, which in turn are represented as finished bodies of propositions linked by logical and inferential relations connecting sense experience to the higher reaches of law and theory.

From this perspective, scientific revolutions alter the content of successful theories, but not the logic of scientific rationality and knowledge. Indeed, the empiricist's logical standards (e.g., Carl Gustav Hempel's deductive-nomological model of explanation, prediction and confirmation) provide the grounds for evaluating the scientific revolutions of Copernicus, Galileo, Johannes Kepler, Sir Isaac Newton, and Albert Einstein. This entire development could be reasonably represented as a logical, cumulative progress. On the philosopher's standards, this progress is one in which, for example, better confirmed theories of wider explanatory scope replace lesser predecessors, whose errors are corrected, and whose sound results are preserved and extended by their successors. The history of the best science(s) illustrates but does not alter the logic of scientific knowledge. So understood, the rationality of science makes it possible for humankind's best theories to converge on the truth concerning lawlike regularities in the world of observed phenomena and, perhaps, the underlying, unobservable entities and mechanisms causally responsible for these regularities.

These achievements of logical empiricism gain one of their last, most lucid and systematic reformulations in Hempel's *The Philosophy of Natural Science*. This work appeared in 1966 four years after Kuhn's *The Structure of Scientific Revolution (SSR)*. Of course many philosophers besides Kuhn challenge one or more of the presuppositions of traditional philosophy of science and reshape the debates in the post-positivist period (e.g. William Van Orman Quine, Wilfred Sellars, Norwood Hanson, Stephen Toulmin, Michael Scriven, Nelson Goodman, Paul Feyerabend, Mary Hesse, etc.). But Kuhn's challenge in *SSR* is probably unique in the avalanche of criticisms, rebuttals, and new approaches to the history and philosophy of science that it has provoked for decades. Much of this response focuses on Kuhn's notion of scientific revo-

lution and the incommensurability, relativism, and irrationalism it is taken to imply.

KUHN'S CONCEPTION OF SCIENTIFIC REVOLUTION

In effect, Kuhn mobilizes a new conception of the history of science, in which scientific revolution is fundamental and its nature contradicts the formal rationality, normativity, universality, logicism, and progressive cumulativeness sought by logical empiricists, and still embraced in new forms by contemporary philosophers (e.g., scientific realists). The philosophical thrust of Kuhn's notion of scientific revolution can be tersely expressed as the following claim. It is in the very nature of (a) science that it undergoes not simply changes in the content of its theories, but more fundamentally changes in the very language, problems, goals, and standards that (re)define science, the criteria of scientific knowledge, and membership in the scientific community. This sort of change is what Kuhn's conception of scientific revolution implies, an epistemological change in the requirements of scientific knowledge, explanation, proof, and confirmation. The claim that the essence of science is to generate scientific revolutions, in its own epistemological self-definition, seems like a general philosophical claim. But it is not an *a priori* claim, for Kuhn. Rather the claim is supposed to be justified by showing that it provides the best explanation of the actual development of science, which opens it up to criticism on this score. In any case, this argument gives history a central role in the evaluation of a philosophy of science.

Kuhn's view of scientific development turns on its division into periods of normal science marked by a normative consensus in the scientific community concerning how to conduct inquiry; and periods of scientific revolution, marked by the breakdown of this consensus. Revolutionary periods typically end when the scientific community is redefined on the basis of a new consensus that creates a different framework for normal science. The normative consensus required by normal science involves the existence of a paradigm that all experts accept as the basis of their research. A scientific revolution implies the dissolution of one paradigm and its eventual replacement by another. A paradigm is a concrete solution (e.g., Lavoisier's account of combustion) to a particular problem (why do some substances gain weight in combustion) that members of a scientific community commonly recognize as an exemplar of how to pursue inquiry in a wider domain of phenomena (chemical reactions); phenomena that may prove to be of the same or similar kind as the paradigm first treated. A

group of inquirers only becomes a scientific community when their research generates a paradigm. As the central object of normative consensus, the paradigm guides practitioners in commonly recognizing what counts as a legitimate problem or phenomenon-to-be-explained in the domain of their science. It tells them what concepts, techniques, mechanisms, measurements, and standards must be present for a legitimate solution to the problem, a *bona fide* scientific explanation of it. Normal science is the research undertaken to articulate and extend the paradigm by solving a host of puzzles that arise in the attempt to reduce ever-wider phenomena to its terms.

In this process, the shared commitments of the scientific community grow and encompass the formulation of theories, laws, basic equations, standards of proof, mathematical techniques, and experimental procedures. In some contexts, Kuhn refers to this entire body of commitments as the paradigm. Normal science allows a cumulative progress of scientific knowledge, but it is progress within the paradigm, relative to its standards of puzzle solving and explanation. Normal science breaks down when the paradigm confronts anomalies. Anomalies are problems that it ought to be able to resolve, but over time cannot, and that motivate some practitioners to represent the problem, or attempt solutions in ways that abandon basic components of the paradigm and the normative consensus underlying the research tradition defined by it. For Kuhn, one of the best examples of scientific revolution is the abandonment of the premodern chemistry of the phlogiston theory and the theory of elective affinity, due to Lavoisier's oxygen theory of combustion and the new compositional paradigm of Daltonian chemistry.

KUHN'S CONCEPTS OF INCOMMENSURABILITY

Phlogiston chemistry succeeded in explaining many qualitative phenomena with a paradigm that posits the existence and properties of phlogiston (the presence of phlogiston solves the problem of why the metals have common metallic qualities lacking in their ores). But the phlogiston theory explained the combustion of a substance as a loss of phlogiston that implied weight loss. The phenomenon of weight gain in combustion constituted an anomaly for phlogiston theory because despite serious attempts, no phlogiston chemist succeeded in accounting for it within the constraints of this paradigm. As inquirers abandoned different components of the phlogiston paradigm, in order to accommodate the phenomena of combustion, the road was paved for a revolutionary transformation in the very concepts, language,

questions, techniques, data, values, aims, and standards at the heart of chemistry. In *SSR*, Kuhn stresses the discontinuities marked by scientific revolution and advances his most controversial claim that these discontinuities imply incommensurability between the paradigms or theories separated by scientific revolutions. Incommensurability seems to imply that pre- and postrevolutionary theories cannot be compared because there is no common measure to ground comparison. Such a view is at opposite poles from the project of logical empiricists and their heirs to establish a framework of concepts and standards external to particular theories and their history, and capable of grounding critical evaluation, and judgments of cognitive progress.

But there are different lines of argument in Kuhn concerning the sources and implications of incommensurability. Rival theories are said to be incommensurable because (1) they do not share the same language, or conceptual scheme, and the language of one is not translatable into the language of the other, or a neutral observation language; (2) they do not perceive or recognize the same observational data; (3) they do not address or acknowledge the same problems; (4) they do not embrace the same standards of theory-evaluation or the same interpretations of standards; and (5) they do not live in the same world. While all of these claims are present in Kuhn's argument, which of these sources of incommensurability is most basic, or most defensible? How much room does it leave for continuity and commensurability at the other levels of scientific development? These questions raise the issue of what role reasoning plays in Kuhn's conception of scientific revolution, and how large a role is played by psychological and sociological processes.

Kuhn's very notion of a paradigm and a paradigm-change is sociological in so far as it involves the collective mechanisms through which a scientific community builds up and protects a shared allegiance to its norms and social control over who is and is not a member. He characterizes scientists' embrace of a new paradigm in psychological terms as a gestalt-switch, a leap of faith, and a conversion experience. What role, if any, is left for reason (confirmation, proof, prediction, falsification) in scientists' acceptance of (1) a new conceptual scheme; (2) a new domain of observational data; (3) a different agenda of problems; (4) different standards of theory-evaluation; or (5) a novel world? Which of these is the most basic source of incommensurability? Kuhn's readers and critics focus on different strands of this account of scientific revolution and in response, move philosophy of science in different directions.

THE FIRST WAVE OF CRITICS: INCOMMENSURABILITY AS TOTAL MEANING CHANGE AND EXTREME RELATIVISM

The first influential line of criticism (Scheffler 1967, 1972; Shapere 1964, 1966, 1971) takes Kuhn's notion of scientific revolution to rest on a radical, holistic conceptual relativism and an implausible view of systematic meaning-variance between paradigms and theories. In essence, on this reading, the first alleged source of incommensurability, paradigms' unique untranslatable language of science, is taken to imply all the others, incommensurabilities of data, problems, standards, and worlds. Each scientific paradigm is imprisoned within its own framework of theoretical concepts whose internal relations determine the unique meaning of each concept and all observation terms employed by the paradigm. On this reading of Kuhn, scientific revolutions change the meaning of all concepts employed by the exponents of a paradigm (e.g., planet in the Copernican revolution) and no translation is possible between the rival languages of science.

With no language in common, it is easy to see why Kuhn would also hold that rival paradigms cannot share common observational data, problems, standards, or worlds. But in that case the advocates of rival paradigms cannot communicate or argue and thus their commitments (beliefs, values, etc.) must be explained by nonrational psychological and sociological processes. Furthermore, retrospective evaluations of theories of the sort grounded in the criteria of traditional philosophy of science (degree of confirmation, explanatory scope, etc.) will be impossible; because there will be no neutral language that permits comparisons of their empirical content. Thus Kuhn's concept of scientific revolution leads to a radical incommensurability and extreme relativism, on which every paradigm, or research tradition, is justified on its own terms, and none is any better than another (better confirmed, etc.).

For the first wave of Kuhn's critics, the resulting position of Kuhn's analysis is incoherent and a "reductio" of its own premises. If rival paradigms cannot be compared or communicate in a common language, in what sense are they rivals? With no common subject matter, there is nothing for them to disagree about. In that case, there would be no difference between a shift of paradigms (or scientific revolution) within a scientific discipline (Cartesian to Newtonian physics) and the movement of inquirers from one area of inquiry into an entirely different one (physicists becoming neuroscientists).

Furthermore, Kuhn's notion of anomalies implies that rival paradigms share some common observational data about which they disagree, and which allow comparisons of their empirical content and success. In that case, they must share some concepts or language, undermining the thesis of radical conceptual incommensurability. Finally the holistic conception of scientific meaning depends on a failure to distinguish sense and reference, among other flaws. Even if the reference of a concept changes ("planet" from Ptolemy to Copernicus; "mass" from Newton to Einstein), there may be sufficient stability of connotation to yield commensurability. On the other hand, when the connotation of observational concepts (temperature of a gas) changes, there is often sufficient stability of reference to allow comparison of paradigms' empirical contents. The development of causal theories of reference reinforced the arguments for continuity of reference (Kitcher 1978, Psillos 1999).

This entire line of criticism located the failure of extreme relativism and radical incommensurability within the terrain of philosophy of language and Kuhn's false starts there. It convinced many philosophers of science that whatever its problems, the tradition of logical empiricism had little reason to worry about Kuhn's notions of scientific revolution and incommensurability.

INCOMMENSURABILITY AS SHIFTS-IN-STANDARDS

A second reading of Kuhn shifts the focus to the strain of argument that bases incommensurability not on language, but rather on shifts in the epistemic standards or values that accompany scientific revolutions (Doppelt 1978, 1980; Zammito 2004). Such changes transform the criteria of theoretical knowledge and successful inquiry, for the field and scientific community in question. An allegiance to the new standards implicit in a paradigm shift typically involves a redefinition of the domain of problems and observational phenomena most important for any adequate theory to explain. These shifts sometimes generate losses in the problem-solving capacity and explanatory power of science, though the epistemic importance of these losses is evaluated differently on the disparate standards implicit in rival paradigms.

The premodern chemistry of the phlogiston theory and the theory of elective affinity generated solutions to a large number of problems that are eliminated from the domain of phenomena-to-be-explained by the modern chemistry instigated by Antoine-Laurent Lavoisier and John Dalton. It could account for the observable properties of a number of substances, solving the problem of

why metals exhibited common metallic qualities, lacking in their ores, and why metals take on acidic qualities as a result of chemical reactions. While such questions could still be formulated in the nineteenth century, the failure to answer them, to explain the observed qualities of compounds, is not taken as a cognitive defect in Daltonian chemistry; even though empirical success with these phenomena was a central criterion of theoretical knowledge for premodern chemistry. Of course the modern chemistry of Lavoisier and Dalton succeeded in solving a whole range of problems (concerning weight relations and proportions in chemical reactions) that were largely unknown until their work. Still, given Kuhn's "loss-of-data" and "shift-in-standards" arguments concerning scientific revolution, on his view, the Daltonian paradigm is not well characterized as simply offering a better, truer, or more rational account of chemical phenomena than its predecessor. For, the premodern and modern paradigms provided explanations of different sorts of observed phenomena, in accordance with different problem-sets, and in line with different standards of adequacy for chemical theory.

Reading Kuhn's argument in this way generates a more moderate notion of scientific revolution, incommensurability, and relativism than the initial critics identified. The argument is compatible with considerable continuity and overlap across paradigms concerning language, observational data, problems, and even standards. The existence and role of anomalies exhibits such overlap. More generally, this reading is compatible with Kuhn's clear recognition that new paradigms often try to, and succeed at, treating many of the phenomena at the heart of their predecessors, and satisfying some of their standards, as well as their own. What, then, is left of incommensurability and relativism, in moderate form? Is there a moderate form of these doctrines?

On the moderate version of Kuhn, advocates of rival paradigms present good reasons and arguments to one another. But because their disagreement is about the standards of their science, and the strength of reasons is relative to such standards, paradigm debates and shifts (scientific revolution) are often marked by an absence of compelling reasons. Equally scientific and rational inquirers can weight the balance of good reasons in contradictory ways that favor the standards and achievements implicit in their rival paradigms. This moderate notion of incommensurability of reasons generates a distinctive Kuhnian version of the underdetermination of theory by evidence. Antirealists often argue that the observational implications of a theory do not confirm the

truth of the theory. Because one can always imagine another theory T1, incompatible with T, with the same confirmed observational implications; the two theories are empirically equivalent but cannot both be true. Realists reply that evidence and confirmation involve more than the mere logical consequences derivable from the theory. Confirmation of a theory by evidence for many realists requires that the theory provide the best explanation of the evidence, in virtue of its simplicity, accuracy, explanatory scope, fruitfulness, plausibility, and unification. Kuhn acknowledges the universality of such epistemic values in science. But he argues that shifts-in-paradigms change the criteria governing their application and their relative importance in determining the best explanation. Premodern and modern chemistry both valued unifying explanation, but embraced different standards concerning what sorts of phenomena required unified explanation.

If theory, or paradigm choice, is underdetermined by evidence, and good reasons, due to Kuhn's shift-in-standards claims, reason (scientific method) alone will not explain scientific revolution. Without glorifying irrationalism or mystical conversion, Kuhn can vindicate the relevance of psychological and sociological factors to explain which particular scientific considerations, in an ocean of conflicting reasons, prove compelling to the practitioners who accept a new paradigm, and why. Moderate relativism thus asserts that scientific development involves revolutions in which a new paradigm triumphs, even though it entails some losses in problem-solving capacity, and is no more rational to accept than its predecessor(s), given the different standards at play in the historical context.

CRITICS OF MODERATE RELATIVISM

This more moderate version of Kuhn's conception of scientific revolution moves its evaluation away from the philosophy of language onto the terrain of epistemological argument. Various critics of Kuhn's shift-of-standards relativism advance arguments based on the existence of external standards, piecemeal bootstrap scientific rationality, naturalist epistemology, and scientific realism (discussed, in turn, below). In the spirit of logical empiricism, some critics argue that Kuhn's emphasis on internal paradigm-specific standards is fully compatible with the existence of external, universal, and non-relative standards of scientific rationality and progress; such as predictive accuracy, explanatory scope, simplicity, completeness, empirical success, unifying power, and the like (Scheffler 1967). Isn't the existence of such independ-

ent standards what makes rational debate between exponents of rival paradigms possible and indeed intelligible as such to us today (Siegel 1980, 1987)?

Kuhn fully embraces the existence of such universal epistemic considerations (empirical success, etc.) in science. But he argues that they function as broad, abstract values of scientific inquiry, whose actual contents are transformed by scientific revolutions. In effect, he takes a moderate relativism of internal standards to imply a relativity of external standards to paradigms. But this is not supposed to be an a priori claim about scientific development. Kuhn's studies of normal science, revolution, and scientific debate are supposed to show that exponents of rival paradigms apply the aforementioned epistemic values in very different ways, yielding concretely different standards of explanation, simplicity, unification, and even accuracy (what counts as an acceptable measure of experimental deviation of prediction from observed result).

But does Kuhn's moderate relativism concerning the role of reasons and standards in scientific revolution imply any relativism concerning long-run scientific progress? The tradition of logical empiricism concerns the context of justification, not discovery. As long as there are external standards of theory-assessment sufficient to establish that science overall attains cognitive progress, Kuhnian short-run losses in problem-solving and standards need not imply any global relativism. As Kuhn himself observes these losses are often recouped in the long run. Though the chemical revolution initiated by Lavoisier abandons the effort to explain the qualities of compounds, these problems are taken up and resolved in twentieth century science. Newtonians first accepted and later abandoned the Aristotelian and Cartesian standards requiring a mechanical explanation of motion, thus gravity (no action-at-a-distance). Einsteinian physics produces an explanation of gravity without any loss to the data and problems handled by Newtonian science.

Kuhn explicitly claims that scientific development exhibits progress in the sense that there are dramatic increases in the number, range, variety, and accuracy of its problem-solutions (even if it is not consistently cumulative, step by step). Another critic seizes on problem-solving effectiveness as the way to accommodate Kuhn's historical insights while overcoming his relativism concerning scientific rationality and equivocations about cognitive progress (Laudan 1977). He seeks to establish an external standard of problem-solving effectiveness with a theory-neutral calculus for identifying, counting, and weighing the various empirical and conceptual prob-

lems tackled, solved, and unsolved in rival or successive research traditions. This account follows Kuhn's historicism in allowing that rival research traditions (a looser, more flexible concept than paradigm) are often committed to different problems, different standards of solution, different criteria for individuating, counting, and weighing important kinds of conceptual and empirical problems.

By accepting the historical relativity of problems, solutions and standards, the externalist model of maximal problem-solving effectiveness runs the risk of collapsing into a Kuhnian moderate relativism concerning the rationality of scientific change and cognitive progress. For example, on the externalist model, the objective importance of a problem (how much it affects a tradition's problem-solving effectiveness) is elevated if rivals tackle and solve it. Against this criterion, the problem solutions taken to be most important in establishing the chemistry first, of Lavoisier, and later, of Dalton, address phenomena that were largely unknown to premodern chemists (e.g., the alchemists) and thus should enjoy less epistemic weight than they were accorded and needed in the making of the chemical revolution. Once external standards are historicized, relativism threatens.

A second critique of Kuhn's notion of scientific revolution follows Kuhn in rejecting self-sufficient external standards and embracing a historicized account of scientific rationality, but one without relativist implications. These critics argue that there are typically good reasons for altering the standards and goals of scientific inquiry, internal to the historical context of shared beliefs in which the change occurs. If the context of shared belief can provide inquirers with a justification for preferring some standards over others, then paradigm change is in principle entirely rational and explainable by the reasons in its favor, without recourse to psychological and sociological dynamics (Siegel 1980, 1987). Some philosophers adopt a multilevel, piecemeal, and gradualist model of scientific change to show precisely how and why the background context of scientific change provides inquirers with good reasons to make these changes (Laudan 1984, Shapere 1984).

The gradualist model directly challenges Kuhn's holistic historiography of normal and revolutionary science. Normal science is supposed to be ordered by a global framework of tightly interwoven concepts, problems, theories, standards, and aims, such that change of any one component implies alterations in all the others. Scientific revolutions are supposed to imply something like a sudden and wholesale break with the entire frame-

work (extreme incommensurability and relativism), or at least its alleged foundational standard(s) (moderate relativism), and the acceptance of a wholly new one.

Gradualist critics argue that if this is what scientific revolutions are supposed to be, then either there are not any, or very few. The process of rebuilding the framework of scientific inquiry is piecemeal and gradual. Change at one level—whether it is theoretical beliefs, empirical observation, methodological standards, or broad cognitive aims—does not dictate change at all other levels; and no one level is foundational for all the rest (Laudan 1984). On the other hand, change on any one of these levels can be justified by elements of continuity and agreement at other levels, even if we accept the Kuhnian view that there are no sacrosanct or permanent aims and standards with which to anchor justification (Shapere 1984).

To take a well-known example, consider the decision of inquirers during the nineteenth century to abandon an exclusive commitment to the Newtonian standard of inductive generalization, which ruled out the epistemic rationality of using observation to support inference to unobservable entities and processes. The strict empiricist inductive standard of proof was widely thought to be responsible for the great Newtonian achievement and its decisive methodological break with the vacuous, speculative hypotheses of Cartesian physics. But in the eighteenth and nineteenth centuries, scientific practitioners became increasingly interested in explaining well-known electrical, chemical, magnetic, gravitational, optical, and other sorts of observed phenomena.

This set of aims took their inquiries beyond the strictures of the Newtonian empiricist standard. The most successful theories (George Lesage, David Hartley, Roger Boscovitch) of these phenomena posited the existence of an unobservable ether(s) in order to account for them. The scientific credibility of these problem-solutions, turned on a new standard of theory-assessment, the method of hypotheses (hypothetico-deductive reasoning). Scientists like Lesage defended this standard as a sound route to genuine knowledge, alongside inductive empiricism. Some members of the scientific community became increasingly committed to the aim of explaining these phenomena, outside the privileged domain of Newtonian physics, and to the aether theories that realized this aim. These shared commitments provided good reason to defend the method of hypothesis and abandon inductivism as the sole standard of genuine knowledge (Laudan 1981, 1984).

The other theorists are neither practitioners of normal Newtonian science nor participants in a revolution-

ary break with it. They do not question the Newtonian achievement and do not reject the standards and aims associated with it. By justifying a wider standard of inference than Newtonians allowed, aether theorists grounded the empirical success of their theories and enhanced the internal consistency of their commitments. Scottish natural philosophers like Thomas Reid stuck to the Newtonian standard and thus argued that the ether theories could not embody genuine scientific knowledge. If one thinks of the parties to these debates as members of the scientific community, then it is much more loosely structured than the notion of a paradigm implies. Its members have different levels of commitment to the disparate components of the framework of scientific inquiry at the time. The framework itself may exhibit tensions or inconsistencies that different inquirers seek to resolve in different ways. The gradualist model of scientific change exploits cases like this to show how the historical context provides inquirers with good reasons for embracing a new standard of scientific knowledge.

Some philosophers press the gradualist model further to argue for a historical conception of progressive scientific rationality on which reasoning over time produces dramatic improvements in the standards, methods, and goals of good reasoning itself. For example, ether theories are ultimately discredited, and the method of hypothesis is supplanted by more demanding criteria of abduction (e.g., William Whewell's consilience of inductions). Nonetheless, the ether theorists' defense of an inference to unobservables, to account for observed phenomena, improved subsequent scientists' understanding of how knowledge can be achieved and what form it might take.

Scientific development can thus be understood as a process of learning how to learn, one in which reasoning generates progressive historical improvements in the very goals, methods and standards of good reasoning itself (Briskman 1977, Brown 1977, Laudan 1984, Nickles 1993, Shapere 1984, Zammito 2004). Such accounts of scientific rationality are characterized as bootstrap rationality, the internalization of reasons, evolutionary epistemology, or nonrelativist historicism, depending on which version is at issue. This dialectical growth in scientific rationality itself accounts for a feature of science that Kuhn himself acknowledges—the extraordinary increase in the power of science, what it can do, by way of problem-solving effectiveness, prediction, explanation, and control. If scientific development implies the enlargement of one's very capacity to reason, this account blunts the epistemologi-

cal force of Kuhn's notion of scientific revolution (shifts-in-standards, moderate relativism).

THE TURN TO NATURALISM AND REALISM

A closely related development is the emergence of naturalized epistemology. The project of naturalistic epistemologists is to characterize scientific knowledge and its methods on the basis of empirical inquiry, not historical narrative of any sort. Scientific method can be characterized as whatever processes of inference are in fact most effective and reliable means to the ultimate aims of science. Some normative naturalists treat the history of science as a body of empirical evidence that can be used to determine which scientific aims are in fact realizable, and which methods are most effective in realizing them (Laudan). Reliabilist naturalists appeal to our best current sciences in order to determine which methods or mechanisms of belief-formation are most reliable in producing true beliefs (Goldman 1988). From the naturalists' standpoint, scientific change and new standards are not evaluated by the internal reasons provided by the historical context to the inquirers reasoning in that context. Rather naturalists appeal to external empirical knowledge in order to determine whether reliable and effective methods have been followed and this determination does not depend on the reasons or standards that inquirers themselves employ. From this standpoint, rational change and progress in science are evidenced by increases in the reliability of its methods and theories in generating true beliefs.

This naturalistic turn provides another way of circumventing Kuhn's notion of scientific revolution and the historical relativism (of reasons) it implies. One problem for naturalist epistemology arises from the plurality of aims or values in scientific inquiry, a central point in Kuhn's work. The naturalist cannot be expected to identify effective and reliable methods, or processes, of scientific inquiry, if its aim is left indeterminate. Is the aim explanation or prediction, maximal accuracy or unification, simplicity or completeness, etc? Even if one settles on a unitary aim such as truths about the world (as reliabilists hold), this does not settle the methodological debate between realists and empiricists, or instrumentalists.

If the aim is theoretical truths concerning the unobservable causes of observational regularities, as scientific realists argue, then they may also be correct in treating inference-to-the-best explanation as the most effective and reliable method. If the only realizable aim is exclu-

sively truths at the observational level itself, or instrumental reliability (as empiricists stress), then other methods may be more effective. Indeed, the debate between empiricists and realists is precisely over the reliability of inference-to-the-best explanation as a method of confirming the truth of theories. While there are good arguments on both sides, they are not mainly the sorts of purely empirical considerations that naturalist epistemology speaks to. They are closer to the normative and conceptual disagreements brought to light by Kuhn's conception of scientific revolution (Dopplet 1986, 1990, 2001).

Indeed Kuhn's conception places him squarely on the side of instrumentalists. His conception allows that science exhibits cognitive progress in the sense that our best current theories possess vastly more empirical success, instrumental reliability, and problem-solving effectiveness than their predecessors. For scientific realists, the great empirical success of our best current theories provides compelling evidence that they are true. If they weren't true, so realists argue, their great success would be a miracle (Boyd 1973, 1984, 1992; Putnam 1975, 1978; Psillos 1999). The realist view of theories provides the best explanation of their success. On the other hand, Kuhn takes his conception of scientific revolution to support an uncompromising antirealism. He sometimes claims that a scientific revolution alters the world, or more weakly, the aspects of the world central to scientific perception and inquiry (Hoynigen-Heune 1993). In addition, scientists' standards of success and truth shift in scientific revolution. For these reasons, scientific revolution is supposed to preclude the cognitive progress of theories toward the truth concerning the underlying, unobservable structure of reality.

Between Kuhn's virulent antirealism, and the argument of current scientific realists, there is a fundamentally different view of which features of science are most important to account for. Kuhn's notion of scientific revolution focuses on shifts in standards and aims. Scientific realists emphasize the remarkable success of our best science in realizing the ambitious standards and aims it has. If what is most important to explain is not how science arrived at its current standards and aims, but rather why the best current theories are so successful in realizing them, then scientific realists' account offers a powerful antidote to Kuhn's relativism.

Yet, scientific realists have not been entirely immune to Kuhn's historicism. One of the most influential criticisms of scientific realism stems from a careful consideration of past science (Laudan 1984). The realist appeals to

the truth, or approximate truth of our best theories, to explain their empirical success. But how will the realist explain the fact that many outdated theories (e.g. the luminiferous ether theory of the propagation of light) were also empirically successful but false, to the best of our knowledge. Indeed, doesn't this record of false but successful theories constitute good inductive evidence that our currently most successful theories are also probably false? In response, scientific realists have turned to these historical cases and provided realist accounts of their successes and failures (Psillos 1999). Taking stock of the history, realists seek to narrow the range of truly successful theories, limit the components of theories confirmed by their success, and secure a greater continuity of reference than Kuhnian revolutions allow.

However its merits are finally judged, Kuhn's conception of scientific revolution drove a very fruitful wedge between traditional philosophy of science and historicism. It realigned the relation of philosophy of science both to the history of science, and studies of specific scientific practices, theories, and controversies. This realignment helped bring a fuller range of sciences such as biology into the purview of philosophy of science, where physics once reigned supreme. The debates inspired by Kuhn's work helped generate the new approaches to scientific method, rationality, and progress previously described. All told, there is more than a little irony in the fact that some of the most vocal and relentless critics of Kuhn's notion of scientific revolution ended up learning, and teaching, the most from it. What first appeared to many as Kuhn's revolution of irrationality, later proves to be a central component in a larger process of rethinking the aims and methods of philosophy of science itself.

Gerald Doppelt (2005)

SCOT, MICHAEL

(fl. 1217–c. 1240)

Michael Scot was an astrologer, alchemist, and translator of Arabic and Hebrew works into Latin. Born in Scotland late in the twelfth century, he spent most of his active life in Toledo, Palermo, and mainland Italy—perhaps at Rome. He first appears with any degree of certainty at Toledo in 1217, when he finished a translation of al-Bītrōgī's (Alpetragius's) *Liber Astronomiae* (On the spheres). The next certain date is 1220, when he is reported to have completed a Latin translation of Aristotle's *Historia Animalium*, probably at Toledo. He seems to

have become favorably known at the papal court, for he was offered the archbishopric of Cashel in Ireland in 1225. He refused the office because of his ignorance of Gaelic. Probably during this period he produced the translation of Aristotle's *De Caelo et Mundo*, along with several other physical works of Aristotle with their Arabic commentaries by Averroes. It was these commentaries that were to be so influential among the Schoolmen for the next several generations. About 1228, as nearly as can be judged, Scot entered the service of Emperor Frederick II in Sicily, or at his court at Palermo, as his official astrologer. While there, he wrote his compendious *Liber Introductorius*, a general survey of the whole science of astrology, and the *Liber Particularis*, similar in content but much briefer, intended for popular use. He also composed a *Physiognomia*, a general handbook of physiological science. All three works were dedicated to the emperor and brought Scot a wide reputation. From this second, Sicilian period of his life comes the *Abbreviatio Avicenne de Animalibus*, probably done in 1231, in answer to Frederick's request for more scientific information about the animal kingdom. It was also during this period that Scot wrote *De Arte Alchemie* in which he reported having witnessed and himself verified alchemical experiments performed by Arabs, Jews, Spaniards, and north Africans.

Because of his renown many other works have been ascribed to him, such as a commentary on John of Holywood (Sacrobosco) titled *De Sphera* and a Latin translation of Maimonides' *Guide of the Perplexed*, but these attributions lack any proof or, indeed, likelihood. Scot's great contribution remains his work of translation from Arabic and Hebrew sources of Aristotle's zoological works, the work of al-Bītrōgī, the commentaries of Averroes on Aristotle, and the zoological work of Avicenna. Dante Alighieri consigns him to hell as a magician.

See also Aristotle; Averroes; Avicenna; Dante Alighieri; Maimonides.

S. Harrison Thomson (1967)

SCOTISM

Scotism refers variously to (1) a loosely identified body of views thought to be original with or characteristic of John Duns Scotus, (2) a tradition of texts, doctrines, and approaches that traces back to him, and (3) a *via* (“way” or perhaps “school”) that had an institutional presence in the universities of the fifteenth through the seventeenth centuries. In the first sense scholars today speak of “logical Scotism” in the work of authors who perhaps have never heard of Scotus. In both the first and the second senses scholars ask whether Charles Sanders Peirce, who had read Scotus with care but was a fiercely independent thinker, was a Scotist. In the third sense scholars inquire about the presence of Scotism in the arts and theology faculties of particular universities in the sixteenth century and investigate its fortuna. Confusion can arise (and has arisen) from running these together and one should take special care to distinguish them all from the influence of Scotus—which was so pervasive in the later Middle Ages that almost every metaphysician and theologian of note felt obliged to locate himself with respect to the Subtle Doctor.

Scotus died young (perhaps as young as forty-two) and left an enormous number of fertile ideas in various stages of development. His immediate students and followers, particularly those at Paris, among whom one might add William of Alnwick (c. 1275–1333), Antonius Andreas, Nicholas Bonet (?–1360), Francis of Marchia (1290–1344), Francis Meyronnes (c. 1285–after 1328), and Petrus Thomae (c. 1280–c. 1337), took up those they found congenial and developed them in somewhat different directions. Within twenty years of Scotus’s death there had also grown up a number of different explicitly critical responses to his teaching exemplified in the work of Petrus Aureoli (1280–1322) on the one hand and William of Ockham on the other. At least four elements of Scotus’s thought became identified with him in particular: In metaphysics the view that there was an isomorphism between the structure of concepts and the structure of things and the associated postulation of *formalitates*; on the borderline of metaphysics and theology a distinctive argument for the existence and infinity of God; in theology the doctrine that Mary had been conceived immaculately, that is, without the stain of original sin; and also the view that the divine will was the ultimate cause of the truth of all contingent truths. It is not at all clear that any of these doctrines was entirely original with Scotus and so one should be cautious in locating someone who does not self-identify as a follower of Scotus as a Scotist in

either the second or the third senses of the word simply because the person maintains some of them.

In the first half of the fourteenth century it seems to have been the metaphysical doctrines just mentioned that received the most attention. The key concept of a *formalitas* and the closely associated notion of an *haecitas* as a formal principle of individuation attracted the attention of most of the metaphysicians of the period. There even grew up a distinctive genre of treatise *De Formalitatibus* that studied these notions. Scotus’s argument for the existence and infinity of God as developed both in his *Ordinatio* and the treatise *De Primo Principio* became celebrated soon after his death Thomas Bradwardine devoted his enormous *De Causa Dei* to correcting, elaborating, and refining it and there was considerable controversy about it throughout the century. Scotus’s distinctive views about the role of the divine will in the truth of contingent truths also attracted considerable attention. Much of this attention was hostile, but it was intense for all that. In the fifteenth century the doctrine of the immaculate conception, which had been rejected by Thomas Aquinas but maintained by many thinkers including Scotus, Ockham, and Pierre d’Ailly, became associated with Scotus more particularly and by the middle of the sixteenth century, as other alternatives to Thomism faded from the theological scene, it became thought characteristic of Scotism.

The earliest references to a Scotist school or at least to a group of thinkers whom one can identify as such, are, as is quite typical in the Middle Ages, by figures who see themselves as opposed to it. In 1331 Adam Wodeham, no friend of the view, identifies the isomorphism between things and concepts as characteristic of an unnamed group of thinkers who hold it to be the fundamental principle of metaphysics. By 1400 Jean de Gerson (1363–1429) identified a group holding this view as the *formalizantes* and set himself vigorously against it. In the fifteenth century one finds thinkers like John Foxoles both self-identifying as Scotists and attempting to work out histories of the movement with which they identified. Peter of Candia (c. 1340–1410) is a particularly interesting thinker of this period much influenced by Scotus whose work has received modern study.

Scotus’s works were intensively studied throughout the Franciscan order during the fifteenth through the seventeenth centuries and the fortunes of that order considerably influenced his reception. Scotism as a *via* (school) reached its zenith in the seventeenth century. The Irish Franciscans claimed Scotus as their own (in the middle of the seventeenth century the prominent philosopher-the-

ologian John Ponce [1603–1670] even wrote “Scotus Hiberniae restitutus” to prove the point) and under the leadership of Luke Wadding (1588–1657) a team at the Irish college of St. Isidore in Rome prepared an edition of Scotus’s works (Lyons 1639) that has been foundational for all subsequent editions. The considerable intellectual resources of the Franciscan order in the seventeenth century led to interesting philosophical development and debate of which the most celebrated instance is that between Ponce and Bartholomew Mastrius (1602–1673) over the nature of possibility.

SEARLE, JOHN

(1932–)

John R. Searle was born in Denver Colorado in 1932. He attended the University of Wisconsin (1949–1952), then

Oxford (1952–1959) as a Rhodes Scholar. He earned his PhD (Oxford) in 1959 and went to the University of California Berkeley, where he remained, and where he is Mills Professor of the Philosophy of Mind and Language. Over the past forty years, Searle has been working on a selection of problems in philosophy at three levels of description: mind (the basic level), language (the middle level), and society (the highest level). In each case Searle can be seen as following a certain pattern: he proposes analyses of facts at one level of description in which they cause, are realized in, or constitute, facts at another higher level. Brute facts can count as institutional facts, and some objective brute facts can cause and realize other, subjective, brute facts. Like phenomenological analyses, Searle’s approach is not classically reductive, but there is an explanatory asymmetry: higher level phenomena often are to be explained in terms of lower level phenomena (explaining is not explaining away). However, as contrasted with phenomenology, this procedure does not require that conditions revealed by analysis be revealed in experience.

MIND, COGNITIVE SCIENCE AND RATIONALITY

Searle (1981) presents the “Chinese Room” argument against “strong artificial intelligence,” the view that mental states are and can be explained by programs running on the brain, by claiming that programs will give you at best the syntax or structure of thoughts, but not their semantics, their intentionality (aboutness). Searle (1985) schematized such intentional states $S(r)$, where S is a psychological mode, such as believing, and r is a representational or propositional content: that snow is white. S typically determines the “direction of fit” of the intentional state: beliefs have a mind-to-world direction of fit, intentions and desires have a world-to-mind direction of fit. Together, S and r fix conditions of satisfaction. For beliefs this is a truth-condition, for intentions and desires it is a fulfillment-condition. Some intentional states, such as perception, memory, intention, have the added feature of causal self-reference, in that their conditions of satisfaction make reference to their own causal role. All intentional states are linked in a causal and logical network, and function against a background of nonintentional capacities and abilities.

Consciousness, Searle (1992) argued, is not only a unified qualitative experiential state, it is a natural biological phenomena caused by and realized in the brain. Furthermore, according to the “connection principle,” all mental states are either conscious, or available in principle

to consciousness. This principle if correct would rule out many of the kinds of preconscious mental states favored by cognitive science, including linguists' "cognized" principles of language, vision theorists's algorithms for the computation of stereopsis, and philosophers's "functionalist" analysis of intentional states. Furthermore, "cognitivism," the view that brains are computers (digital or connectionist) is mistaken, because being a computer is an observer-relative fact and not an intrinsic feature of the neuroscience of brains. Mental states are ontologically subjective in that they depend on a mind to exist, but they are epistemically objective in that claims about them are true or false independently of opinion.

Searle (2001) claims that human agents can act rationally because they have free choice. There are three potential "gaps" or decision points in the chain leading to free, voluntary action: a gap between having reasons and forming a prior intention to act; a gap between the prior intention and the intention-in-action that causes the movement that counts as the action; and the gap between segments of temporally extended activities—continuing to act. Acting freely involves selecting a reason to act on, and that reason cannot be causally sufficient for the action.

LANGUAGE, SPEECH ACTS, AND SOCIETY

According to Searle (1958), Frege was almost right: the use of proper names is backed by descriptive content, not by any particular one, but by a cluster. No particular predication on a name is necessary, but the disjunction of contents is. This doctrine is the target of Saul Kripke's attack on description theories of names. Searle (1969, 1979, 2001) elaborates and defends the idea that speaking a language is a form of rule-governed behavior, and that the semantics of a natural language is to be given in terms of "constitutive" rules for performing speech acts. These rules "regulate" antecedently existing forms of behavior, or "count as" the creation of a new form of behavior, or both. Illocutionary acts, such as asserting that snow is white, typically have the structure $F(P)$, where F is the illocutionary force (assertion) and P is the propositional content (that snow is white). Sentences typically encode this distinction in devices for indicating the force, F , of the utterance, and devices for indicating the propositional content, P , and these devices are governed by constitutive rules for performing the relevant illocutionary and propositional acts. Each illocutionary act has a distinct (illocutionary) point or purpose, which can be used to taxonomize such acts. Searle and Daniel Vanderveken (1985) propose an illocutionary logic in which relations

between illocutionary acts and forces are captured formally.

Many illocutionary acts can be performed explicitly with the performative formula ("I hereby adjourn the meeting"), in which case the speaker makes a self-referential, self-guaranteeing declaration. Illocutionary acts can also be performed indirectly, and nonliterally (metaphor), and the theory of these forms of communication need not appeal to any special principles beyond the constitutive rules for speech acts, general rationality, and Gricean principles of conversation. Viewed from the lower level of intentional states, the performance of a speech act is the mental imposition of conditions of satisfaction on an utterance, which itself satisfies the intention in action to produce that utterance. Hence Searle's recurrent slogan that all meaning involves "imposing conditions of satisfaction on conditions of satisfaction" (Searle 2001, p. 53). Searle (1995) argues that institutions, and social facts in general, are created when agents collectively impose a new status on things that antecedently do not have it, and go on to attach certain functions to that status. Thus, a piece of paper or metal becomes money when exchange value is assigned to it and accepted. The general form of the creation of such institutional facts is: People collectively accept that X has the power to do A . Such status-functions can be nested within one another creating tangled hierarchies of social facts and organization—money can pay mortgages for property, and that property can then be inherited. Such "collective intentionality" is basic and cannot be reduced to individual or mutual intentionality.

SECOND ORDER LOGIC

Second-order logic is the extension of first-order logic obtained by introducing quantification of predicate and function variables. A first-order formula, say Fxy , may be converted to a second-order formula by replacing F with a dyadic relation variable X , obtaining Xxy . Existential quantification yields $\exists X Xxy$, which may be read “*there is a relation that x bears to y* .” In general relation variables of all arities are admissible. Similarly, quantifiable function variables may be introduced.

SEMANTICS FOR THE SECOND-ORDER LOGIC

A structure, with non-empty domain D , for a second-order language includes relation domains $\text{Rel}_n(D)$ and function domains $\text{Func}_n(D)$. In general $\text{Rel}_n(D) \subseteq \mathbf{P}(D^n)$, where $\mathbf{P}(D^n)$ is the power set of D^n . Similarly, the function domains $\text{Func}_n(D)$ are subsets of the collection of n -place total functions on D . Such second-order structures are called *Henkin* or *general* structures. If X is an n -place relation variable, a formula $\exists X\varphi(X)$ is *true* in a Henkin structure M if there is an n -place relation $R \in \text{Rel}_n(D)$ such that $\varphi(X)$ is true in M when X has the value R . There is a similar definition for formulas of the form $\forall X\varphi(X)$ and for formulas with quantified function variables. A formula φ is a *Henkin semantic consequence* of a set Δ of formulas if φ is true in all Henkin models of Δ .

The relation domain $\text{Rel}_n(D)$ need not contain all subsets of D^n . If $\text{Rel}_n(D) = \mathbf{P}(D^n)$ for each n , we say that each relation domain is *full* (similarly for function domains) and that the structure is *full*, *standard* or *principal*. Second-order logic restricted to full structures is called *full* or *standard* second-order logic. A formula φ is a *full semantic consequence* of a set Δ if φ is true in all full

models of Δ . A formula is *valid* if it is true in all full structures.

In Henkin semantics, the Completeness, Compactness and Löwenheim-Skolem Theorems hold because Henkin structures can be reinterpreted as many-sorted first-order structures. This yields Henkin’s Completeness Theorem: There exists a deductive system DS such that if φ is a Henkin consequence of axioms Δ then there is a *deduction* of φ from Δ using the rules of DS. For further details, see Shapiro 1991, Shapiro 2001, or van Dalen 1994.

EXPRESSIVE POWER

Following Gottfried Leibniz, we may define “ $x = y$ ” as “any property of x is a property of y .” The corresponding second-order definition $\forall x\forall y(x = y \leftrightarrow \forall X(Xx \rightarrow Xy))$ is valid. In contrast with first-order logic, there are *categorical* second-order theories with infinite models: All full models are isomorphic. For example, let Δ be the theory with axioms $\forall x(s(x) \neq 0)$, $\forall x\forall y(s(x) = s(y) \rightarrow x = y)$ and $\forall X[(X0 \wedge \forall x(Xx \rightarrow Xs(x))) \rightarrow \forall xXx]$. Any full model of Δ is isomorphic to the structure $(\mathbf{N}, 0, S)$, where \mathbf{N} is the set of natural numbers and S the successor operation. So, the Löwenheim-Skolem Theorems fail in full second-order logic. Consider the theory $\Delta \cup \{c \neq 0, c \neq s0, c \neq ss0, \dots\}$, with c a constant. This theory has no full model, but any finite subset of it has a full model. So the Compactness Theorem fails, too.

Extending Δ with the recursion axioms for addition and multiplication, we obtain the theory PA_2 whose unique full model up to isomorphism is the natural number structure $(\mathbf{N}, 0, S, +, \times)$. Similarly there is an axiom system whose unique full model up to isomorphism is the ordered field of real numbers, $(\mathbf{R}, 0, 1, +, \times, <)$. More generally there exist second-order formulas expressing cardinality claims inexpressible in first-order logic. The most striking example concerns the Continuum Hypothesis (CH), which says that there is no cardinal number between \aleph_0 and 2^{\aleph_0} . Results due to Kurt Gödel and Paul Cohen imply that the Continuum Hypothesis is independent of standard axiomatic set theory (ZFC). But there is a second-order formula CH^* which is valid just in case CH is true.

If we augment PA_2 with inference rules for the second-order quantifiers and the monadic comprehension scheme $\exists X\forall x(Xx \leftrightarrow \varphi)$, we obtain axiomatic second-order arithmetic, Z_2 . (See Simpson 1998 for a detailed investigation of Z_2 and its subsystems.) One may construct a Gödel sentence G , true just in case G is not a theorem of Z_2 . Now, all full models of Z_2 are isomorphic to

($\mathbb{N}, 0, S, +, x$). So an arithmetic sentence ϕ is true just in case ϕ is a full semantic consequence of Z_2 . G is thus a full semantic consequence of Z_2 but not a theorem of Z_2 . The Completeness Theorem therefore fails; there is no sound and complete, recursively axiomatized, deductive system for full second-order logic. Indeed the set of second-order validities is not recursively enumerable. For further details see Shapiro 1991, Shapiro 2001, or Enderton 2001.

IS SECOND-ORDER LOGIC LOGIC?

Second-order comprehension has the form $\exists X \forall x_1 \dots \forall x_n (Xx_1 \dots x_n \leftrightarrow \phi)$. Should such existential axioms count as logical? Does this violate the *topic-neutrality* of logic? W. V. Quine argued that second-order logic is “set theory in sheep’s clothing” because “set theory’s staggering existential assumptions are cunningly hidden ... in the tacit shift from schematic predicate letter to quantifiable variable” (Quine 1970, p. 68). Another reason for not counting second-order logic as logic is that the full semantic consequence relation does not allow a complete proof procedure.

In reply George Boolos pointed out that the obvious translation from second-order formulas to first-order set-theoretic formulas does not map valid formulas to set-theoretic theorems. For example $\exists X \forall y Xy$ is valid, while $\exists x \forall y (y \in x)$ is refutable in axiomatic set theory. Furthermore $\exists X \exists x \exists y (Xx \wedge Xy \wedge x \neq y)$ is not valid, and so “second-order logic is not committed to the existence of even a two-membered set” (Boolos 1975 [1998], pp. 40–41). Furthermore first-order logic does have a complete proof procedure, but the set of first-order validities is undecidable (Church’s Theorem), while the monadic fragment is decidable. So why is completeness used to draw the line between logic and mathematics rather than decidability?

THE INTERPRETATION OF SECOND-ORDER VARIABLES.

George Boolos (1984, 1985) has provided monadic second-order logic with a novel interpretation: the plural interpretation. Certain natural language locutions that receive monadic second-order formalizations are perhaps better analysed as instances of plural quantification. For example the Geach-Kaplan sentence, “Some critics admire only one another,” may be formalized as $\exists X (\exists x Xx \wedge \forall x \forall y (Xx \wedge Axy \rightarrow x \neq y \wedge Xy))$. This formula is non-first-orderizable (not equivalent to a first-order formula containing just the predicates A and $=$). According to the usual interpretation, its truth implies the existence of a

collection. The plural interpretation reads “There are some [critics] such that, for any x and y , if x is one of them and admires y , then y is not x and y is one of them.” Rather than asserting the existence of a collection, this is a plural means of referring to individuals. Second-order logic can also be applied to set theory. In this context we can interpret monadic second-order quantification over sets as plural quantification.

Jeffrey Ketland (2005)

SELF

In its normal use the English expression “self” is not even quite a word, but something that makes an ordinary object pronoun into a reflexive one (e.g., *her* into *herself*). The reflexive pronoun is used when the object of an action or attitude is the same as the subject of that action or attitude. If I say Mark Twain shot *himself* in the foot, I describe Mark Twain not only as the shooter but as the person shot. In this sense “the self” is just the person doing the action or holding the attitude that is somehow in question. “Self” is also used as a prefix for names of

activities and attitudes, identifying the special case where the object is the same as the agent: self-love, self-hatred, self-abuse, self-promotion, self-knowledge.

“The self” often means more than this, however. In psychology it is often used for that set of attributes that a person attaches to himself or herself most firmly, the attributes that the person finds it difficult or impossible to imagine himself or herself without. The term *identity* is also used in this sense. Typically, one’s sex is a part of one’s self or one’s identity; one’s profession or nationality may or may not be.

In philosophy the self is the agent, the knower and the ultimate locus of personal identity. If the thought of future reward or punishment is to encourage or deter me from some course of action, I must be thinking of the person rewarded as me, as myself, as the same person who is now going to endure the hardship of righteousness or pass up the enjoyments of sin in favor of this ultimate reward. But this same self comes up in much more mundane transactions. If I pick up the cake and shove it in this mouth rather than that one, is it not because I think it will be me, the very same person who picks up the cake, that will have the pleasure of tasting it?

A straightforward view of the self would be that the self is just the person and that a person is a physical system. This view has been challenged on two fronts. First, the nature of freedom and consciousness has convinced many philosophers that there is a fundamentally non-physical aspect of persons. The second challenge stems from puzzling aspects of self-knowledge. The knowledge we have of ourselves seems very unlike the knowledge we have of other objects in several ways, and this has led some philosophers to rather startling conclusions about the self. In his *Tractatus*, Ludwig Wittgenstein tells us that “I am my world” and that “the world is my world” (1961, 5.63, 5.641). This should lead us to the rather surprising conclusion that I am the world, or that at least Wittgenstein was. He draws at least one conclusion that would follow from this: “at death the world does not alter, but comes to an end.”

The contemporary philosopher Thomas Nagel has been led to a possibly less radical but still quite dramatic view. According to Nagel, when he says “I am Tom Nagel,” at least in certain philosophical moods, the “I” refers to the “objective self,” which is not identical with but merely contingently related to the person Tom Nagel. This self could just as well view the world from the perspective of someone other than him (Nagel, 1983). We need to discuss the puzzling features of self-knowledge that give rise to such views.

SELF-KNOWLEDGE

“Self-knowledge” seems to have a straightforward meaning: cases of knowledge in which the knower and the known are identical. But this does not seem sufficient. The philosopher Ernst Mach once got on the end of a bus and saw a scruffy, unkempt, bookish-looking sort of person at the other end. He thought to himself,

- (1) That man is a shabby pedagogue.

In fact, Mach was seeing himself in a large mirror at the far end of the bus. He eventually realized this and thought to himself:

- (2) I am that man.
- (3) I am a shabby pedagogue.

Now consider Mach at the earlier time. Did Mach have self-knowledge? In our straightforward sense it seems that he did. He knew that a certain person was a shabby pedagogue and, furthermore, that person was him. The knower and the known were the same. But this is not what we mean by self-knowledge. Self-knowledge is something Mach really had only when he got to step (3), when he would have used the word *I* to express what he knew.

Self-knowledge seems peculiar. First, it seems “essentially indexical.” Statement (3) expresses self-knowledge because of the word *I*; it is hard to see how Mach could have expressed self-knowledge without using the first person. If he said “Mach is a shabby pedagogue,” he would be claiming to know only what everyone else may have known. It does not seem that there is any objective characterization *D* of Mach, such that knowing that *he* is a shabby pedagogue amounts to knowing that *D* is a shabby pedagogue (Castañeda, 1966, 1968; Perry, 1990, 1993).

Secondly, we seem immune to certain sorts of misidentification with respect to self-knowledge. If we learn, in certain ways, that someone is in pain, then we cannot miss the fact that it is we who are in pain. That is, if Mach discovers that he has a headache in the ordinary way that a person discovers she has a headache, he can scarcely be wrong about *who* has the headache, if the range of choices is “I/you/that man,” and so forth. Of course he can be wrong if the range of choices is “Mach/Freud/Wittgenstein,” and so on, for he might not realize which of those people he is (Shoemaker, 1984).

Third, self-knowledge seems to play a unique cognitive role. If Mach desires that *he* do so and so, and believes that *he* can do so and so by executing such and such a

movement, then he will execute that movement without further ado (Perry, 1990).

AGENT-RELATIVE KNOWLEDGE

At least some of these peculiarities of self-knowledge can be explained by taking self-knowledge to be a species of agent-relative knowledge. There are two quite different ways of cognizing objects (people, things, places, and times). We can think of them via their relationship to us, the role they are playing in our lives at the moment of thought: the object I see; the present moment; the place I'm at; the person I'm talking to. We need to think about things in the first way, when we are picking up information about them perceptually or interacting with them, since ways of knowing and acting are tied to these agent-relative roles. I can learn about the here and now by looking; I can learn about the person I am talking to by asking questions, and so forth.

But these agent-relative roles cannot be our only ways of thinking about objects of more than passing interest to us. Different objects play the same agent-relative roles at different times, and at any given time many of the objects we wish to retain information about will not be playing any agent-relative role for us. And we cannot accumulate information along such roles. Suppose I am in Tokyo on Tuesday but return to Palo Alto on Friday. From the facts that on Tuesday I truly thought "Japanese is the official language *here*" and on Friday I truly thought "Senator Stanford used to live near *here*" it does not follow that there is some place where Japanese is the official language and near which Senator Stanford used to live.

In order to retain and accumulate information about objects, to construct and maintain a coherent picture of the world, we need to have a way of conceiving of objects as existing independently of us, as occupying and then ceasing to occupy various agent-relative roles. That is, we need objective ways of thinking about objects. We keep track of them by names or descriptions that do not depend on their relationship to us: Cordura Hall, 4 p.m., June 23, 1995, the southernmost town in Santa Clara County, Aurora Fischer. These serve as our fundamental ways of thinking about those objects. Recognition consists in connecting our objective ways of thinking of objects with the roles those objects play at a given moment. Consider the knowledge I might express with "Today is July 4." This is knowledge that a certain day, objectively conceived ("July 4"), is playing a certain role in my life; it is the present day, the day on which the thinking and speaking take place. This kind of knowl-

edge, "knowing what day it is," is quite crucial to successful application of other, more objective knowledge. If I know that the party is on July 4 and know that today is July 4, then I will form the right expectations about what the day will be like.

Similarly, I may be in Kansas City and know that Kansas City is a good place for a steak dinner. But if I do not know that I am in Kansas City, if I do not realize that Kansas City is playing the "here" or "this city" role in my life at this moment, I will not be able to apply the knowledge that Kansas City is a good place for a steak dinner.

And again, I may know that Aurora Fischer has important information about my schedule, but unless I realize that the person I am talking to is Aurora Fischer, I will not apply this information and say, "Can *you* tell me where this afternoon's meeting is?"

These kinds of knowledge are, like self-knowledge, "essentially indexical." We use *now* and *today* to express our knowledge of what time it is and *here* to express our knowledge of where we are. These locutions are not reducible to names or objective descriptions, just as *I* was not. I cannot express what I say when I say, "The meeting starts right now" by saying "the meeting starts at *D*" for any description *D* of the present moment.

We are also immune to certain sorts of misidentification when we use certain methods of knowing. There is a way of finding out what is going on around one, namely opening one's eyes and looking (Evans, 1985). Now when one learns what is going on in this way, one can hardly fail to identify the time at which this is happening as now and the place as here. And finally, the forms of thought we express with *now* and *here* seem to have a unique motivational role. If I want to do something here and now, I will simply do it.

SELF-KNOWLEDGE AS AGENT-RELATIVE KNOWLEDGE

"Self" is really the name of such an agent-relative role, that of identity. As with other agent-relative roles, there are special ways of knowing and acting that are associated with identity. If Mach had wished to know, during the interval while he was confused, if the shabby pedagogue he was seeing had lint on his vest, he would have had to walk over to him and look. If Mach had wanted to know if he himself had lint on his vest, he could have simply lowered his head and looked. Had he done this, he would have had no doubt about whom the lint was on. If Mach found lint and wanted to brush it off, he would engage in self-brushing, a quick movement of the hand across one's

front that each of us can use to remove lint from our own vest and no one else's.

Unlike the other agent-relative roles, identity is permanent. I will talk to many people, be in many places, live through many times in the course of my life. But there is only one person I will ever be identical with, myself. Hence, accumulation along "I" is valid, unlike accumulation along "here" or "now" or "that man."

Earlier we rejected the straightforward account of self-knowledge, as knowledge about a person by that very person. Now we can put forward an alternative. Self-knowledge is knowledge about a person by that very person, with the additional requirement that the person be cognized via the agent-relative role of identity. This agent-relative role is tied to normally self-informative methods of knowing and normally self-effecting ways of acting. When these methods are employed, there will be immunity of misidentification as to who is known about, or who is acted upon.

This role can serve as a person's fundamental concept of himself or herself. In this way our self-conceptions have structures that are different from our conceptions of other individuals of importance to us. If we understand the special way in which a person's self-knowledge is structured, we do not need to postulate anything but the person himself or herself for the knowledge to be about.

SELF-DECEPTION

If weakness of will is a pathology of agency, then it is natural to regard self-deception as a pathology of cognition. Self-deception is a species of motivated believing in which the cognition of a subject is driven by desire towards the embrace of some proposition—typically, "in the teeth of the evidence." Here we may think of the alcoholic, the terminal cancer patient, or the anorexic, who, even while in possession of compelling evidence of his condition, insists, sincerely, that it is just not so. Many investigators require that, more than this, the self-deceiver must be understood to bring about his deception intentionally and knowingly in pursuit of the doxastic embrace of some motivationally or affectively favored proposition. Were this so, self-deception would seem to involve the sort of deep or internal irrationality distinc-

tive of weakness of will. For just as the weak-willed individual knowingly and intentionally acts against her judgment of what she takes herself to have best or sufficient reason to do, so the self-deceiver, on this picture of the phenomenon, knowingly violates her own norms or standards of reasoning—she comes to believe what she also believes there is insufficient reason to believe.

Producing a coherent account of how this is so has proved a vexing matter. Other investigators have argued that self-deception can be fully explicated without appeal to a subject's intentionally aiming to bring about her own deception against her current regard for the facts, and therefore without implicating this sort of deep irrationality. Notwithstanding these disputes, it seems clear that when we charge a subject with self-deception, we aim to offer both an explanation of how it is that a subject came to hold or retain a belief and a negative appraisal of the subject's belief-forming behavior.

In a quite literal way, the impetus behind the philosophical problem of self-deception springs from the force and puzzlement attached, in certain circumstances, to the question "How *could* he believe that?" We are all familiar with various unpleasant features of our cognitive lives, and there is no doubt that we do reason in ways that, as a matter of fact, violate epistemic norms that we endorse (the term 'epistemic,' meaning of or relating to knowledge, is derived from the Greek, "epistēmē"). The sources of such failures are many: we are subject to a profound confirmation bias, prone to be taken in by the vividness and salience of data (Nisbett and Ross 1980), forgetful and subject to fatigue, and so forth. Very plausibly, self-deception raises more pressing difficulties. In such cases, securing an answer to the question "How *could* he believe that?" compels us to reflect upon such issues as the nature of belief, doxastic agency, the unity of the self, and epistemic rationality and irrationality, among many others.

THE PHENOMENON

As suggested above, much controversy surrounds the effort to characterize the process of self-deception, the nature of the phenomenon itself, and the sort of irrationality characteristic of the phenomenon. Notwithstanding this disagreement, clear instances of what we call "self-deception" come readily to mind. The stock and shopworn example of the husband who, even though in possession of compelling evidence of his wife's infidelity, nonetheless insists upon her faithfulness is a case in point. Our husband may generate richly ornamented stories the apparent aim of which is to explain away the, by our lights, dispositive evidence of the fact of his wife's

affairs. He may focus upon the occasions on which his wife has displayed great solicitousness and affection towards him, and he may well regard these data as clear and compelling evidence of her continued love for him. Moreover, he may subject evidence that strongly points towards his wife's infidelity to sustained and withering critical scrutiny, while precipitately embracing data indicative of her continued faithfulness. In short, our hapless husband repeatedly searches for reassuring evidence and probes various hypotheses in a sustained and continuing fashion in order to arrive at and then to retain the favored belief against various threats. Core cases of self-deception would, then, appear to involve a subject engaging in strategies the aim of which is the embrace of some proposition(s).

TRADITIONALISM ABOUT SELF-DECEPTION

How are we to characterize and explain such behavior? An approach to such cognitive misadventures that we can term "traditionalism" aims to assimilate the dynamics of self-deception to those of interpersonal deception. As Mary Haight writes: "[I]f A deceives B, then for some proposition(s) *p*, A knows that *p*; and either A keeps or helps to keep B from knowing that *p*, or A makes or helps to make B believe that $\sim p$, or both" (1980, p.8). These lexical considerations (Mele 2001) for the traditionalist view, then, make it perfectly natural to characterize our self-deceived husband as knowing or believing that his wife is unfaithful and as aiming and ultimately succeeding in bringing it about that he comes to believe that she is, in fact, a loyal spouse. On such a model, the husband is not simply credulous, not merely stupid or epistemically careless; nor is he simply seduced by the salience or vividness of various data, or taken in by the confirmation bias. He is not, then, in the view of the traditionalist, merely a wishful thinker or believer. He aims at his own deception; he works hard to deceive himself. How else, we may ask ourselves, can he possibly believe that his wife is faithful? Why does he engage in such byzantine strategies, the apparent point of which is to avoid the implications of the evidence? Because he knows, or at the least strongly suspects, the truth—that she is unfaithful.

A typical traditionalist, then, will hold that our husband:

1. Believes that his wife is unfaithful (or believes that he ought rationally to believe that his wife is unfaithful).

2. Engages in intentional activity the aim of which is the acquisition of the belief that his wife is faithful.

3. Believes, at least for a time, both the belief adverted to in (1) and the belief adverted to in (2).

Donald Davidson, in an extremely influential essay titled “Deception and Division,” embraced these three conditions. As he puts it in a much-cited passage:

The acquisition of a belief will make for self-deception only under the following conditions: A has evidence on the basis of which he believes that *p* is more apt to be true than its negation; the thought that *p*, or the thought that he ought rationally to believe that *p*, motivates A to act in such a way as to cause himself to believe the negation of *p*. The action involved may be no more than an intentional turning away from the evidence in favor of *p*, or it may involve the active search for evidence against *p*. All that self-deception demands of the action is that the motive originate in a belief that *p* is true ... and that the action be performed with the intention of producing belief in the negation of *p*. Finally, and this is what makes self-deception a problem, the state that motivates the self-deception and the state it produces co-exist. (1985, p. 145)

It should be noted that Davidson’s rationale for a contradictory or inconsistent belief requirement for self-deception is not—as it is on some accounts of self-deception (Demos 1960)—that the self-deceiver literally *lies* to himself. Davidson takes, very plausibly, the project of lying to oneself to require a self-defeating intention. Rather, Davidson takes the philosophical problem of self-deception to be a matter of our being forced to come to grips with a continuing and synchronous irrational or inconsistent state—a state he takes to be distinctive of self-deception. Davidson characterizes self-deception as a condition brought about by my intentionally causing myself to believe against what I also believe and *continue* to believe to be the weight of the evidence. As a result, and not surprisingly, Davidson argues that the characterization of such a state requires the postulation of mental partitions, divisions in the mind.

THE PUZZLES OF SELF-DECEPTION. Still, whatever the attractions of such an account, it is difficult to fathom just how this sort of mental gymnastics can be carried off. Immanuel Kant was, for example, clearly puzzled by the looming difficulties here; as he put it in his *Metaphysical Principles of the Virtues*, “Since a second person is required when one intends to deceive, deceiving oneself

deliberately seems in itself to contain a contradiction” (cited in Darwall 1988, p. 411).

In a bit more detail, traditionalism has been taken by many to give rise to two difficulties. First, there is what Alfred Mele has termed the “static puzzle” (1987, 2001). The very state of mind of the self-deceiver might strike us as deeply puzzling. How can it be that the self-deceiver believes that *p* and also believes that not-*p*? There is no doubt, of course, that human beings often harbor inconsistent beliefs, where one of the beliefs is repressed or otherwise not currently or fully available to a subject’s awareness. What is harder to understand is a case in which both such beliefs are fully available to a subject.

Second, such an account makes for a strategic puzzle. Annette Barnes puts a version of the difficulty so: if I am to be self-deceived, I must “as deceived, be taken in by a strategy that, as deceiver I know to be deceitful” (1997, p. 18). The self-deceiver might well, as Davidson suggests, intentionally turn his attention away from evidence supportive of the threatening belief and seek out evidence of the favored belief with the aim of inducing in himself the latter. But if this plan is to succeed, it is not easy to see how the self-deceiver could fail to be wholly taken in by his ruse. That is, a condition of success of such a project would appear to be that the conviction that he ought rationally to believe the epistemically sanctioned proposition be exiled or come to be regarded as epistemically undermined *before* he can come to accept that his favored proposition is true. This is, however, very near to the sort of gambit recommended by Blaise Pascal in order to induce belief in the existence of God. There is no doubt that we can intentionally bring about conditions the result of which is that we come to believe what, at the time we brought about those conditions, we took ourselves to have no good reason to believe. This, however, does not appear to make for the deep and synchronous irrationality stalked by Davidson.

It should be noted that more modest traditionalists, while rejecting the contradictory belief requirement, have argued that the cognitive biasing in self-deception must be intentional (Talbot 1995), or that the self-deceiver need only actively avoid troubling recalcitrant evidence (Bach 1997).

Notwithstanding the difficulties to which traditionalism about self-deception has been alleged to be prey, its attractions and allure are clear. It works admirably to capture some very powerful vernacular (and philosophical) intuitions about the phenomenon. Traditionalism would sharply distinguish self-deception from putatively less puzzling phenomena such as wishful believing, for the

self-deceiver knowingly and actively brings about her deception, while the wishful believer is merely duped. Insofar as the self-deceiver succeeds in getting herself to believe what she also believes is not so, she would appear to be guilty of a profound form of epistemic irrationality. In addition, the sort of doxastic tension, instability, and fragility the traditionalist aims to describe has seemed to many the hallmark of self-deception. Lastly, insofar as the self-deceiver intentionally and knowingly brings about her deception, she is clearly blameworthy.

Predictably, perhaps, the modeling of self-deception upon interpersonal deception has tended to provoke three sorts of response. The first is outright skepticism about the phenomenon. As Mary Haight puts it: “[S]elf-deception is literally a paradox. Therefore it cannot happen” (1980, p. 73). The second response is a reconceptualization of self-deception as less a purely cognitive or doxastic affair and more an existential (or “actional”) matter. Herbert Fingarette’s pioneering work, *Self-Deception* (1969), is notable example of this tack. He writes of the self-deceiver that he “is one who is in some way engaged in the world but who disavows the engagement, who will not acknowledge it even to himself as his. That is, self-deception turns upon the personal identity one accepts rather than the beliefs one has” (p. 66). In this respect, Fingarette’s is a powerful development and reworking of themes from Jean-Paul Sartre’s famous discussion of “bad faith.” Finally, in the third response one can cleave to the interpersonal model in literal fashion but seek to avoid the difficulties via a very robust partitioning or homuncularist account of self-deception. This is David Pears’s account. He writes that cases of self-deception are to be explicated by appeal to a “subsystem” or homunculus that “is built up around the wish for the irrational belief [e.g. the husband’s belief that his wife is faithful]. Although it is a separate centre of agency within the whole person, it is, from its own point of view, entirely rational. It wants the main system to form the irrational belief, and is aware that it will not form it, if the [belief that there is no good reason to so believe] is allowed to intervene. So with perfect rationality it stops its intervention” (1984, p. 87; see also Pears 1986). Mark Johnston (1988) develops a series of powerful objections (e.g., “Why should the deceiving subsystem be interested in the deception” (p. 64)) to homuncular explanations of self-deception.

DEFLATIONIST ACCOUNTS OF SELF-DECEPTION

A second family of accounts, “deflationism,” aims to circumvent many of the difficulties the traditionalist regards

as fundamental to the posing of the problem of self-deception. Alfred Mele, Mark Johnston, and Annette Barnes have all developed noteworthy deflationist accounts. According to deflationists, self-deception is a matter of coming to believe that *p* as a consequence of biased cognitive processing that is itself the product of the various motivational states of the subject. Such accounts very often take their cue from a rejection of the lexical considerations in favor of traditionalism (Mele 1987, 1997, 2001; Barnes 1997; Johnston 1998). So, for example, it is plausibly argued that there are many clear cases of interpersonal deception that involve neither the deceiver’s knowledge of the proposition the deceived comes to believe, nor intentional deception. But if this is so, there is no obvious reason to require these conditions when it comes to the characterization and, ultimately, the explanation of self-deception. Rather, if, for example, the process of self-deceiving oneself must be understood to be mediated by the subject’s intention to come to believe the favored and epistemically suspect proposition, this must be established by appealing to the fact that an explanation of particular features of the phenomenon itself *requires* such intentional activity. This is what deflationists deny. Core cases of self-deception, it is insisted, can be fully explained without appeal to the psychological exoticism characteristic of many versions of traditionalism.

Alfred Mele’s is the most influential of deflationist accounts. According to Mele, the following conditions are jointly sufficient for a subject’s entering self-deception in acquiring a belief that *p*.

1. The belief that *p* which *S* acquires is false.
2. *S* treats data relevant, or at least seemingly relevant, to the truth value of *p* in a motivationally biased way.
3. This biased treatment is a nondeviant case of *S*’s acquiring the belief that *p*.
4. The body of data possessed by *S* at the time provides greater warrant for not-*p* than for *p*.

(2001, p. 51; see also Mele 1987, p. 127)

The account is notable for what it does not include. There is no requirement that the subject must intentionally bring about his deception, nor is there a contradictory belief requirement. It should be noted, as well, that the motivational states mentioned in (2) will typically be desires for states of affairs; for example, our husband’s desire that his wife be faithful. This is to be distinguished from familiar traditionalist accounts according to which our husband not only desires that his wife be faithful but,

in addition, desires that he believe (or come to believe) that his wife is faithful; it is by virtue of the possession of this latter desire that, by the lights of the traditionalist, the husband comes to self-deceive himself. (Dana Nelkin [2002] has argued that, on pain of counting cases that do not involve self-deception as self-deception, the deflationist, like the traditionalist, must appeal to a subject's desire to believe.)

Mele, in particular, has emphasized the ways in which the motivational states of a subject can harness various sources of cognitive bias. Our husband's desire that his wife is faithful may trigger positive misinterpretation of data, negative misinterpretation of data, and selective evidence gathering and attention. Moreover, familiar "cold" or unmotivated sources of bias may also be triggered by motivation. That our husband desperately wants his wife to be loyal may make data indicative of her faithfulness more vivid as well as more salient. (We do, after all, tend to think about the objects of our desires.) Additionally, it seems clear that motivation will influence the selection of which hypotheses we begin testing with and so may trigger the confirmation bias.

DIFFICULTIES FOR DEFLATIONISM. Needless to say, it has been argued that various features of core cases of self-deception render the deflationist account implausible. William Talbott (1995), for example, has argued that not only is intentional self-deception possible in a single coherent self but, additionally, that we must appeal to an agent's intention to bias her cognition in favor of a particular proposition regardless of the truth of that proposition, if we are to explain various distinctive features of the phenomenon.

First, the process of self-deception might be regarded as too complex, too light-fingered and strategic to be the result of a non-intentional mechanism or process. Indeed, in core cases of self-deception—cases like that of our husband—the subject explains away just what needs to be explained away, he searches for just the evidence he needs in order to come to believe the favored proposition, he does not look just where he must not look, and so forth. This is just the sort of behavior characteristic of means-end rationality, and so of intentional behavior. Moreover, if the processes mediating self-deception are nonintentional, if such processes are "launched" as a simple result of our inhabiting various motivational states, why is it that human beings do not invariably bias their cognition in the direction of motivationally favored propositions? Happily, we do not always become self-deceived that *p* when we powerfully desire that *p*. Self-

deception is in this sense "selective." Again, it would seem that an extremely plausible explanation of why it is that I do come to bias my cognition when I do is that I intend to do so. (It is to be emphasized that Talbott takes our self-deceptive intentions to bias our cognition to be *unconscious* intentions. Annette Barnes [1997] and Ariela Lazar [1999] have developed a number of powerful objections to the notion that unconscious intentions play a crucial role in the explanation of self-deception.)

FACING THE QUESTION: "P OR NOT-P?" Does the deflationist have the resources to respond to these difficulties? Much recent discussion of these issues has drawn on the social psychological investigation of lay-hypothesis testing. Consider the task of any hypothesis tester—including the prospective self-deceiver. He faces questions of the form: "*p* or not-*p*?" The effort to settle any such question will involve costs to the agent in the form of time, and energy spent in the task of hypothesis testing. What is central to this "pragmatic" account of hypothesis testing is another sort of cost involved in the settling of such questions: the cost of anticipated errors as noted by Friedrich (1993) and Trope and Liberman (1996). In aiming to settle a question, a subject aims to end her uncertainty, to reach her "confidence threshold" at which time hypothesis testing is ended. As such, there will be costs associated with settling the question in favor of *p*, when *p* is false (false positives), and costs associated with settling the question in favor of not-*p*, when *p* is true (false negatives). In brief, what is crucial to this account is that with regard to many such questions, the costs associated with such errors will be asymmetric rather than symmetric. As such, there will be what James Friedrich calls a "primary error," an error that the subject is preponderantly motivated to avoid. This error, not surprisingly, is fixed by the values, aims, and interests of the cognizer. Such asymmetric error costs, in turn, fix asymmetric confidence thresholds. The result is biased hypothesis testing and the striking appearance of intentional guidance toward the doxastic embrace of a favored proposition. As Friedrich (1993) puts it: "Lay hypothesis testers are always motivated by accuracy, in the sense that they want to detect and minimize particularly costly errors" (p. 357).

Consider the case of our husband. He must settle the question, "Does she or doesn't she?" His primary error is fixed by his desires and interests. As such, we can easily imagine that his primary error, the error he is most powerfully motivated to avoid, is the error of believing that his wife is unfaithful when she is not. This, then, generates asymmetric confidence thresholds. As a result, he will demand powerful and compelling evidence if he is to

accept that she is unfaithful, while requiring relatively little data to accept that she is faithful. As this is so, the model predicts that our husband will subject data suggestive of her infidelity to powerful critical scrutiny whereas he accepts data suggestive of her fidelity without serious investigation. The account promises a nonintentional explanation of the apparently strategic behavior of core cases of self-deception. It should not be forgotten, of course, that hypothesis testing is typically an amalgam of the intentional and non-intentional. *Any* hypothesis tester who faces the question “p or not-p?” does aim to settle that question. She knows, as well, of the means of which she must avail herself (seeking evidence, asking questions of those “in the know,” etc.) if she is to resolve her uncertainty. So the issue, it seems, is not whether the self-deceiver engages in any intentional behavior in coming to believe as she does. Rather, the issue is whether she *must* be understood to possess an intention to settle her question in some particular direction.

Moreover, it seems that the pragmatic account of hypothesis testing offers an explication of why it is that we do not invariably come self-deceptively to bias our cognition in favor of what it is that we anxiously desire to be so and, so, promises at least a tentative response to the selectivity problem. Again, whether an individual engages in biased hypothesis testing will be determined by the full range of the subject’s interests. So, for example, Talbott (1995) notes that hurtling down a steep mountain road and hearing unfamiliar and frightening noises when I depress my car’s brakes, I am not likely to come to believe that there is nothing amiss, even though there is no doubt that I very much want it to be the case that my brakes are just fine. Indeed, given that the error costs associated with believing my brakes are in working order when they are not are terrifically vivid, I may be likely to come to believe in biased fashion that my brakes are failing. (For skepticism concerning whether a pragmatic account of hypothesis testing holds an answer to the selectivity problem in its full generality see Jose Bermudez [2000].)

This last example indirectly raises the problem of “twisted” or “unwelcome” cases of self-deception (Mele 1999, 2001; Barnes 1997; Lazar 1999; Scott-Kakures 2000). It is indeed a striking fact that self-deception is not always a matter of coming—in biased fashion—to believe just what is desired (directly or indirectly) to be so. Indeed, overprotective parents come in strikingly biased ways to believe that their children are suffering from grave illnesses. Some subjects come to believe, on the basis of scant evidence, that their spouses are *unfaithful*. And, of course, we all have our favorite hypochondriac.

Though the matter is much disputed, such cases would appear to constitute at least a presumptive difficulty for familiar accounts of self-deception. Such cases do, however, appear to be explicable by appeal to the pragmatic account of hypothesis testing. Consider: A busy executive, driving to her work, is nearly hit by a careless motorist as she nears her freeway on ramp. As a result, it may be that she comes, later in her commute, to conclude that many drivers she passes are careless and so constitute a danger. This is not surprising, as she has been made vividly aware of the very high cost of failing to conclude that x is a bad driver if he is. As a result of these asymmetric error costs and the associated asymmetric confidence thresholds, she is apt to demand overwhelming evidence before concluding that x is a safe driver, and she is likely to require very little evidence to bring her to the conclusion that x is a bad driver.

According to the deflationist, then, the irrationality present in self-deception is not an irrationality that requires us to appeal to the traditionalist’s psychological machinery. Indeed, the irrationality present in self-deception is an irrationality with which we are all very familiar—it is a matter of biased reasoning. In this sense, self-deception, according to the deflationist, is not the cognitive pathology it has historically been understood to be. Much of the appeal to traditionalism springs from the intuition that only some distinctive cognitive pathology could explain the self-deceiver’s turning away from the proper aim of belief: truth. In this way, it may well be that, for the deflationist, the price of making self-deception appear more familiar is that what we are apt to regard as “normal” hypothesis testing will come to seem more suspect and less familiar.

SELF IN INDIAN PHILOSOPHY

The human phenomenological experience of the universe consists fundamentally of the self or subject encountering a world of objects. Thus the two main objects of philosophy are the subject or the self—its nature and constitution—on the one hand, and the universe, along with its nature and constitution, on the other. Indian philosophy is no exception to this rule.

This experiencing self is referred to by several terms in Indian philosophy, the one most widely used being *ātman*. The word is usually derived from the root *an*, which means "to breathe"; apparently the fact that the perceiving self is an animate being who faces other animate beings and inanimate objects is central to its emergence as the marker of the self. It is called *purua* when its distinction from inanimate nature or *prakti* is emphasized, and it is called *jīva* when the *ātman* is viewed as caught up in the cycle of *saṣāra* or birth and death, freedom from which becomes a goal of this empirical self (*jīva*). In many systems this freedom is attained when the *jīva* or empirical self discovers its true relationship to the *ātman* or metaphysical self. This is the essential theological structure of the school of Indian philosophy known as Vedānta. But virtually each school of Indian philosophy possesses its own conception of the self or *ātman*, which must now be examined. Such an examination is facilitated by a review of the conception of the self in each of the nine schools of Indian thought. Although this standardization is relatively recent (Halbfass 1988, p. 353) it is worth employing because it enables one to present the concept of the self across the various schools with some measure of coherence. These nine schools, usually listed in order, are the Cārvāka (of Lokāyata), Jaina, Bauddha, Nyāya, Vaiśeika, Sāṅkhya, Yoga, Mīmāsā, and Vedānta.

CĀRVĀKA

According to the Cārvāka school, the body itself constitutes the self (*deha eva ātmā*); of course, what is meant is that the conscious body constitutes the self. However, this immaterial element of consciousness in the body is considered an epiphenomenon of the material components of the body, in a manner reminiscent of scientific materialism. The Cārvāka school would establish the plausibility of the emergence of a property not contained in the elements by their coming together on the analogy of water, which possesses the quality of wetness, a property not possessed by the two gases of which it is composed. There is no question then of postmortem survival

according to this school, as consciousness perishes with death. It therefore emphasizes making the most of life, with a pleasant death serving as the counterpart of salvation. Thomas McEvelley (2002) notes that these doctrines are similar to the ones Plato attributes to the *physiologoi*.

JAINA

According to the Jaina school, the self consists of the soul or *jīva* which occupies the body. The soul is formless but it can occupy a body just as light might occupy a room. It is a striking feature of the Jaina view of the self that this *jīva* is said to be coextensive with the body. In view of the fact that the soul occupies the body, it can be said to occupy space, as the body does, and may even be said to be capable of extension, as when the body grows. The whole range of existence, including plants and minerals along with insects and so on, possesses a conscious soul, and if such consciousness—which is characteristic of the soul—is not apparent, it is because it is dormant under the influence of karma. In Jainism karma is considered a very fine material substance that can permeate a soul, just as motes of dust might permeate light. Jaina soteriology consists of ridding the *jīva* of such matter, which keeps it weighed down in *saṣāra*, so that, freed from it, it can rise to the top of the “universe” and be free forever. According to Jainism, knowledge is the natural attribute of the *ātman*, which is kept in check by *ajīva* or inanimate components of our being. “The eyes, for example are viewed here not as an aid to seeing, but as a check in the absolute sight of the soul” (Hiriyanna 1949, p. 61).

BAUDDHA

While the Cārvāka school does not believe in an *ātman* and denies anything like liberation, and the Jaina school believes in both, Buddhism denies the existence of a self or *ātman* while upholding liberation from rebirth in the usual Indic sense. According to Buddhism, continuity is possible without identity; hence there is no need to postulate a self that is reborn, for the next birth can be viewed as being caused by the present in the process of coming to an end, like an echo. Nirvāṇa brings silence to the re-echoing chamber of *saṣāra*. The Buddhists seem to create many apparent logical difficulties for themselves by denying a permanent self or *ātman* but according to them the other systems create their own existential problems by believing in one. The Buddhist critique of a substantial ontology is very thoroughgoing; according to this critique, nothing whatsoever in this world possesses a permanent substratum (*sabbe dhammā anattā*). The permanence or lack of it in the self has been a major issue

in the Hindu-Buddhist interface (Chakrabarti 1999, chapter 5, appendix).

NYĀYA AND VAIŚEIKA

The concepts of the self in the Nyāya and the Vaiśeika schools have much in common and hence are presented together. According to the Nyāya and the Vaiśeika school, the soul or *ātman* is eternal, but consciousness is not its inherent property. Consciousness arises when the self or *ātman* is conjoined with *manas* or the mind, which is, however, by itself inert. The soul or *ātman* differs from other atomic or all-pervasive objects in that, unlike them, it is potentially capable of consciousness. The selves are numerous and all-pervading but remain distinct in the state of release because of the property of *viśeṣa*, which accounts for things being different that are in other respects all alike—for example, two atoms that are otherwise identical are not numerically one. The self has no consciousness in the state of release because such a state involves the absence of *manas*. The *ātman* in Nyāya is a unique substance that possesses the attributes of cognition, emotion, and conation and the qualities of desire, aversion, pleasure, pain, volition, and knowledge. The Vaiśeika school provides a longer list (Organ). As these are not perceived by the external senses and are not physical, they must belong to a nonphysical substance such as the soul. However, although consciousness or knowledge is an attribute of the *ātman*, it is not inseparable from it. The soul is thus an independent substance, but consciousness is an accidental property of it. In order for conscious states to arise, *manas* must come into play, hence the otherwise cryptic remark that “the true self is broken up here, we may say, into two ‘selfless elements’” (Hiriyanna 1949, p. 91). Scholars such as McEvelley (2002) note parallels here with Aristotelian thought.

SĀNKHYA AND YOGA

The concepts of the self in the Sāṅkhya and the Yoga schools are also sufficiently similar to be treated together. In Sāṅkhya the self is called *purua* or soul and represents pure consciousness, in opposition to *prakṛti*, which represents matter. The self loses its inherent consciousness by mistakenly identifying itself with the body as involved in the process of *saṣāra*; the self is utterly passive and merely a spectator but mistakes itself for an actor and thus undergoes the ups and downs of the cosmic drama. Although the word *purua* is often used in the singular, in reality the system allows for a plurality of *puruas*, all consisting of pure consciousness, but distinct from each other and *prakṛti* or matter. The *purua* in Sāṅkhya and Yoga

is an uncaused, eternal, all-pervading, and changeless reality, which witnesses change as a transcendent subject distinguished by pure consciousness that can itself never become an object of knowledge. Salvation consists of this discrimination (*viveka*) that one is pure spirit and not the mind with whose derivative reality one identifies oneself. The system of Yoga with its eight limbs or constituent elements is meant to guide one, through a series of meditations, to the realization of this ultimate transcendent witnessing subject as distinct from the mind, body, and ego just as the surface of the mirror is totally independent of the objects that are reflected in it but appear included in it.

MĪMĀSĀ

The concept of the self in Mīmāsā is broadly similar to that found in Nyāya and Vaiśeika, but there are some differences. The list of specific qualities characterizing the self is similar but not identical, with Mīmāsā dropping those of dharma and adharma and adding that of *śakti* or potency. The most significant difference however consists of the fact that while according to the Nyāya-Vaiśeika school knowledge is a quality of the self, according to Mīmāsā it is an activity of the self.

VEDĀNTA

The conception of the self or *ātman* in Vedānta needs to be presented in accordance with the school of Vedānta involved—whether it is Advaita Vedānta, Viśiādvaita Vedānta, or Dvaita Vedānta. Thus the exact conception of the *ātman* depends on whether we are dealing with the “non-dualism of the qualified” (Advaita) or dualism (Dvaita). Prior to identifying the self in these three schools of Vedānta, however, it might be useful to indicate the concept of the *jīva* they all share in common on the basis of their reliance on the same foundational texts. Another aspect of the issues relating to the self or *ātman*, which receives relatively greater treatment in Vedānta than in other systems, is its relationship to *Brahman*, or the ultimate reality. It will therefore be useful to begin the discussion of the self in the three Vedantic schools with the conception of it they all share and conclude it with their views on the nature of the relationship of this *ātman* to *Brahman*.

The description of the human person as found in the *Taittirīya Upaniṣad* (II, 1–5) became paradigmatic in later Vedānta. According to this description a person consists of five sheaths within which the *ātman* lies enclosed. Starting from the outside, the first sheath consists of the body made of food (*annamaya-kośa*); within it are the

vital airs that comprise the second sheath (*prāamaya-kośa*). The mind comprises the third sheath (*manomaya kośa*), consciousness the fourth (*vijñānamaya kośa*) and bliss the fifth (*ānandmaya*). In Advaita the self consists of self-effulgent consciousness (*svapṛakāsa caitanya*), which is rather than has consciousness. It is one and the same in all human subjects (unlike Sākhya) and eternally free. Later Vedānta also developed a doctrine of the three bodies that comprise a human being, which ostensibly seems to possess only one body. These are the *sthūla-śarīra* (or gross body) which corresponds to the *annamaya kośa*; the *sūkma-śarīra* (or subtle body), which corresponds to the *prāamaya*—the *manomaya*—and the *vijñānamaya kośa* and the *kāraa-sarīra* (or casual body), which corresponds to the *ānandmaya kośa*. The true self—the *ātman*—lies beyond all the five sheaths and the three bodies or may be said to constitute their nucleus depending on how one chooses to describe it (Kesarcodi-Watson 1994).

According to Advaita Vedānta, the *ātman* is one’s true self and is identical with *Brahman*. Any differences between the two are adventitious, caused by *upādhis* or superimpositions. A popular metaphor illustrates the point as follows: Different jars of different shapes and sizes may contain jar-space. The space enclosed by these jars may appear distinct, but if one breaks the jars, all space becomes one and the same. It was, however, one and the same to begin with—the jars only created ultimately artificial and unreal differences. Thus the selves of all are identical with each other and with *Brahman*.

The *ātman* per se is of the nature of pure consciousness according to Viśiādvaita Vedānta. The self is not pure consciousness, as maintained by Advaita Vedānta, but “a conscious subject called the ego or the ‘I.’” The *ātman* is the self, but this self both *is* and *has* consciousness. Moreover, the self may mistakenly identify with the objects of the world, but it is identical neither with them nor with *Brahman*. It has lost sight of its true nature, one of utter dependence on God or *Brahman*. *Moka* consists in being properly aligned with God through devotion and grace. One important difference between Advaita Vedānta and Viśiādvaita Vedānta is that whereas the *ātman* is infinite in its true nature according to Advaita Vedānta, it is considered atomic or infinitesimal in size in Viśiādvaita Vedānta, but it is able to have knowledge beyond itself through the fact that it not only is but possesses consciousness called *dharmabhūta jñāna*. *Jīvas* or empirical beings are infinite in number according to both the schools, but because of its metaphysical non-dualism, Advaita ultimately concedes only one reality: *ātman* = *Brahman*.

According to Dvaita Vedānta, the *ātman*s are infinite in number. The reason given to justify this is the obvious differences in their experiences (which are considered ultimately only empirical in Advaita Vedānta). They are atomic in size, and, as pointed out, differ from each other. They also differ from God, and the distance posited between them and God is somewhat greater in Dvaita Vedānta than in Viśiādvaita, as indicated by the very designations of these systems. Viśiādvaita Vedānta accepts the “monism of the qualified,” of God as qualified by the *ātman*s, but Dvaita Vedānta is frankly dualistic. Salvation results from the grace of God.

An utterance found in the Chāndogya Upaniṣad famously states “that thou art.” The *that* here is usually taken to relate to *Brahman* and the *thou* to *ātman*, and the interpretation of this seminal utterance in the three schools of Vedānta—the Advaita, the Viśiādvaita, and the Dvaita—is instructive of the differences in the concept of the *ātman* as it is understood in the three schools. According to Advaita Vedānta it means that *ātman* and *Brahman* are identical. “The identity of the denotation of the two terms” has to be realized “while their connotations are different” (Hiriyanna 1949, pp. 163–164). According to Viśiādvaita Vedānta it is to be interpreted as follows: “That’ finally denotes God as having the entire universe as his body; and ‘thou,’ God having the individual soul as his body” (p. 184). According to one interpretation offered by Dvaita Vedānta, the identity here really implies resemblance, for *ātman* “have features like sentience and bliss (though qualified) common with God” (p. 192). The precise idea of the self differs in virtually every system of Indian thought beyond the ones discussed here (see K. P. Sinha 1991).

SELF-INTEREST

Aristotle claims in the *Nicomachean Ethics* that it is the virtuous person “more than any other sort of person who seems to be a self-lover. ... he awards himself what is finest and best of all” (1168b28–30). Aristotle’s thought is that if one pursues things such as pleasure and wealth, one pursues what is base, injuring oneself. Contrast this with the implication of the recommendation “Look out for number one.” This advice is not taken to mean that one should pursue virtue. Rather, the idea is that the interests of others should take second place to one’s own. Virtue is not usually seen as the path of self-interest, especially because it can often involve self-sacrifice. This conflict suggests that effective pursuit of self-interest, or the interests of others, requires an account of the nature of well-being. (Henceforth, I will often use the term *well-being* rather than *self-interest* since that term is used more often in philosophical discussions of self-interest.) In the first part of this article, the major theories are discussed. In the second part, the focus is the importance (or lack thereof) of having an account of well-being for ethics.

THEORIES OF WELL-BEING

The three dominant types of theory regarding well-being are hedonism, desire theory, and objective-list theories. This classification needs refinement, but it is a useful starting point. Take hedonism first. Jeremy Bentham (1776) was probably the most notorious proponent of hedonism. He espouses a type of hedonism that Derek Parfit dubs “narrow hedonism.” Bentham holds that pleasure is what is good for humans; pain is bad. He says, in *An Introduction to the Principles of Morals and Legislation*, that pleasures are homogenous sensations. How well one’s life is going depends on quantity of pleasure—the more the better.

One major objection to this outlook is that there is no felt sensation in common among the experiences that

people find pleasurable. For example, L.W. Sumner (1986) asks us to imagine the difference between the pleasure of going for a walk in the woods and the pleasure of completing a difficult task. Both are pleasures but they have no felt sensation in common.

Henry Sidgwick's form of hedonism, "preference hedonism," avoids this difficulty. He observes, in *The Methods of Ethics*, that "the only common quality [among pleasures] ... seems to be the relation to desire and volition expressed by the general term 'desirable'" (1907, p. 127). Sidgwick says that the judgments of the individual about which feelings are desirable must be taken as final. So pleasures, on this view, are those mental states that are desired by the individual. Some have noted that it strains the meaning of "pleasure" to call all of the mental states that we desire "pleasures." James Griffin's (1986) example citing Freud's desire to be mentally aware, but in horrible pain, rather than take opiates for his cancer pain, is such a case. Perhaps the name of the theory should be modified (as Shelly Kagan suggests) to "preference mental statism."

One strength of preference hedonism is that it respects the authority of the individual in determining which experiences make his or her life go better. Narrow hedonism says that a life of pleasurable sensation is better for the person even if one does not prefer it. Preference hedonism's weakness is that there are some desirable states of affairs that seem to contribute to well-being yet are not, strictly speaking, experiences. Probably, the most famous illustration of this problem is Robert Nozick's (1974) Experience Machine. Nozick asks us to imagine a machine that will give us all of the experiences we desire. He suggests that people would not choose to enter the machine because the experiences would have no relation to reality. Take another case. Imagine that someone is happy because she believes, falsely, that she has devoted friends. Now imagine the same person with happiness resulting from a true belief in devoted friends. Some think that the second is clearly the better life, especially if the second is preferred. The implication is that the fulfillment of desires for things other than mental states contributes to well-being. So, it seems that preference hedonism should be abandoned in favor of desire theory.

If desire theory is unrestricted, then it says that the fulfillment of any desire contributes to self-interest. That this is implausible is nicely shown by Parfit's (1984) case of the stranger: I meet a stranger with a supposedly incurable disease. I desire a cure for him; later, he is cured, though I never know this. It seems ludicrous to say that I am better off when the stranger is cured. This shows that

the desires that should count as contributing to a person's well-being have to be restricted. Parfit suggests that the desire has to be a desire about one's own life. This encompasses, for example, the desire not to be deceived, if it is a desire about one's own life.

But it may be unclear what qualifies as a desire about my own life. Is my desire to live in a just world, or in a world without starvation, a desire about my own life or not? Shelly Kagan (1992) argues that for a state of affairs to matter to my well-being, it has to affect me. My subjective experience is the same whether I am deceived or not. Kagan concludes that it may be that we should restrict the class of desires that are relevant to well-being to desires about mental states. This would mean a return to some form of preference hedonism. Whatever account is better, it is clear that a successful desire theory needs a plausible way to restrict the class of desires that impact well-being.

Now, consider the third type of theory: objective list. According to these theories certain things are good for people, even if they do not want them or have a negative attitude toward them. Consider John Rawls's (1999) famous example of the talented mathematician who wants to spend his life counting blades of grass. Some think that such a life cannot be good for him because the activity is worthless.

However, the difficulty for objective-list theories lies in giving an account of which activities are objectively worthwhile. One prominent account is Aristotle's Function Argument. The function of a flautist is to play the flute, and the flourishing flute player plays the flute well. The function of a human being is to engage in rational activity in accordance with virtue. A good example of a flute player plays the flute well, and a good example of a human engages in virtuous rational activity.

One major worry for the argument, noted by Peter Glassen (1957), is that even if it gives a correct account of human excellence, the inference that it must be good for a human to be a good example of his or her kind is fallacious. It is easy to imagine cases in which the excellent thing fails to be good for the agent. There are prosperous, sensible knaves, and sometimes the good die young. Some form of desire theory is now most commonly thought to be a correct account of well-being.

WELL-BEING AND ETHICS

It may be thought that it is obvious why having a theory of self-interest is important for ethics. If moral theories yield principles about people's duties, and if their duties

include benefiting themselves and others, people need to know what counts as a benefit and what counts as a harm. The classical utilitarians—Jeremy Bentham, John Stuart Mill, and Henry Sidgwick—all think that the only thing that is intrinsically good is welfare or well-being and that the ultimate principle of morality is to perform the action that maximally benefits people.

Other theorists think that there are other goods besides well-being. W. D. Ross (1930) imagines two worlds in which there are equal amounts of happiness and equal amounts of virtue and vice. In the first the virtuous are happy, in the second the vicious are. Ross thinks that the first world is clearly better because of the distribution, even though they contain equal amounts of happiness. G. E. Moore holds, in *Principia Ethica* (1903), that it is good for beauty to exist even if it never affects anyone's conscious life. The deontologists writing in the Kantian tradition think that there is a duty of beneficence, although what is unconditionally good is the good will. However, there are some moral theorists who think that issues about well-being have little importance for ethics. For example, T. M. Scanlon (1998) argues both that individuals do not use the concept of well-being much in their deliberations about their own lives and that moral and political philosophers focus on just distributions of things such as primary goods, resources, or capabilities, rather than well-being. And he thinks that we do not have a general duty of beneficence. Notice, however, that one of the main reasons for the focus on primary goods or resources is the problem of expensive tastes. For example, Ronald Dworkin (1981) imagines a person who needs ancient claret and plover's eggs to be satisfied. Another person might reach an equal level of well-being with something much cheaper such as beer. To equalize welfare would require giving more resources to the first person. Dworkin and other theorists think that would be unjust, so they reject the idea of distributing welfare. The rejection might be correct, but it would be impossible to make the argument without a conception of human well-being.

SELF-KNOWLEDGE

Legend has it that when Chilan of Sparta asked, "What is best for man?" Apollo replied, "Know thyself." Thus, carved into the lintel of the Oracle of Apollo at Delphi were the Greek words "*gnothi seauton*"—"Know thyself" (Parke 1933). We can try to follow this Delphic injunction because we are self-conscious beings, capable of self-reflection.

Sigmund Freud (1923) maintained that we have unconscious beliefs, desires, motives, and intentions, and that extensive use of psychoanalytic techniques is often required to uncover them. Whether there is a Freudian unconscious is controversial, as is whether or not there is suppression or repression in the psychoanalytic senses. Nevertheless, our mental lives can be dissociated. And self-reflection can be as biased as reflection on any topic. Too charitable an attitude towards ourselves can leave us overly sanguine about the strength of our characters or the goodness of our intentions. Too uncharitable an attitude can lead to an exaggerated view of our frailties: We

may see ourselves as more selfish, less kind, and less well-intentioned than we really are. We can engage in wishful thinking, believing something about ourselves on less than adequate evidence because we want it to be true; evasive thinking, which involves turning our attention to other matters when thoughts about ourselves arise that conflict with our self-image; and skeptical thinking, in which we construct hypotheses on the fly to explain away evidence that conflicts with our self-image. Arguably, we can practice self-deception about our motives and reasons, but, in any event, we can certainly unintentionally mislead ourselves about them (McLaughlin and Rorty 1986).

Social psychologists have found that we have a tendency to confabulate. Asked to explain our decisions or actions, we sometimes fabricate explanations, not with an intent to deceive, but apparently with an eye toward justifying or making sense of those decisions or actions; the end result is we are taken in by our own fabrications. Evidence for this proclivity has led some philosophers to maintain that confabulation is so pervasive that our self-reports are just unreliable stories that we tell about ourselves for a variety of aims (Dennett 1991). Many philosophers, however, deny that our fallibility warrants skepticism about the possibility of self-knowledge. And many follow Socrates in holding that there is virtue in heeding the Delphic injunction. The quest for self-knowledge is a way of taking responsibility for ourselves. But it should, of course, be balanced with other activities of value. Yet another Delphic injunction is “Everything in moderation.” Narcissism or self-hatred can result in self-absorption, which is a vice.

Other people are better judges of certain aspects of our character than we are. They sometimes read our emotional state better than we do or remember our view about a certain topic better than we do. Moreover, they can tell us when we are confabulating or not being honest with ourselves. Nevertheless, it seems that each of us is able to know some things about ourselves in ways unavailable to others. Gilbert Ryle denied this claim, arguing that “the sorts of things that I can find out about myself are the same as the sorts of things that I can find out about other people, and the methods of finding them out are much the same. . . . John Doe’s ways of finding out about John Doe are the same as John Doe’s ways of finding out about Richard Doe” (1949, p. 155). He further claimed that “our knowledge of other people and ourselves depends on noticing how they and we behave” (1949, p. 181). According to behaviorism, we can know our own mental states only by observing our own behav-

ior or relying on the testimony of others who have. Of course, often others are better positioned to observe our behavior than we are. Hence, the joke “One behaviorist meeting another on the street said, ‘You feel fine! How do I feel?’” (Ziff 1958). The behaviorist view of self-knowledge seems untenable. We need not rely on observations of our behavior to know whether we are in pain, or are visualizing a red sunset, or are just now thinking to ourselves that behaviorism is untenable.

René Descartes (1985) drew attention to an area of mental life to which we seem to have first-person privileged access and with respect to which we seem authoritative: namely, our current conscious states. Conscious states include bodily sensations (aches, pains, itches, tickles, and the like), sense experiences (visual, auditory, and so on), mental imagery, felt emotions (feelings of fear, and so on), felt urges, and occurrent thoughts. We seem able to know our current conscious states in a way different from the way in which we know those of others. Indeed it seems that to know whether we are in a certain conscious state, we need only turn our attention to whether we are. To know whether we are in pain, for instance, it seems that we need only turn our attention to whether we are in pain.

Of course, we are by no means omniscient about such matters. Beliefs about what conscious states we are in involve the exercise of concepts (Sellars 1963, sec. 62); and we may lack the requisite concepts to know that we are in a conscious state of a certain sort. Even when we have the requisite concepts, we can fail to know simply because of lack of attention to the matter. Moreover, our concepts of types of conscious states are vague. Over the course of a morning we may move gradually from feeling cold to feeling warm, being unable to discern a difference in our thermal sensations from one moment to the next. On route to feeling warm we will pass through borderline cases of feeling cold; and in such cases we cannot know whether we feel cold. Theories of vagueness differ over why we cannot know in such borderline cases. According to semantic theories, the reason is that there is no fact of the matter whether the concept of feeling cold applies, and so they present no limitation to self-knowledge. But given our inability to discriminate cases falling very near the borderline from cases on it, our ability to know whether we feel cold may stop short of the borderline (Williamson 2000).

We can make verbal mistakes in our reports of our conscious states (Broad 1925), and even perhaps conceptual mistakes in our judgments about what conscious states we are in because of less than a full mastery of a rel-

evant concept (Burge 1979). But it has been held that if one has mastered the relevant concepts, one's belief that one is in a certain conscious state will be infallible and incorrigible (Ayer 1940). A belief or thought is infallible just in case it cannot be false; incorrigible just in case it cannot be shown to be false. Descartes (1985) argued, "*Cogito ergo sum*"—"I think, therefore I am"—taking his first-person thought that he thinks to be infallible, incorrigible, and indeed indubitable, such that it cannot be rationally doubted.

"Cogito-thoughts" such as that I am now thinking, and that I am now thinking that P, are indeed infallible, and hence incorrigible: they are true by virtue of my thinking them (Burge 1988). (Similarly, the belief that one has beliefs is true by virtue of one's having it.) Our infallibility in these cases, however, is not due to privileged access to the mental acts of thinking in question. If I write in English that I am writing in English, then what I write is true by virtue of my so writing it; even though I lack privileged access to whether I am writing in English, or even to whether I am in fact writing at all. Indeed, there are scenarios in which I am writing that I am writing in English but in which I fail to know that I am writing in English. The cogito-thought that one is thinking that P is (normally) an expression in consciousness of one's belief that one is thinking that P. But one can believe that one is thinking that P, when the only thought one is having is the thought that P; indeed that is the typical case (McLaughlin and Tye 1998a).

Beliefs to the effect that one is thinking that P are not true by virtue of one's having them. Moreover, they are fallible. To note just one reason: the longer it takes one to occurrently think that P, the more demand is put on short-term memory, and so the less reliable is one's belief that one is thinking that P (Armstrong 1963). Even the belief that we are in pain is fallible. Someone mesmerized by his guru might mistakenly believe that he is in pain solely on the basis of his guru's testimony to that effect. To take a more mundane case, upon hearing the start of the dentist's drill, one might momentarily mistake a feeling of pressure for a feeling of pain (Goldman 2002). (See also the "fraternity initiation" case described in Hill 1991, pp. 128–129.)

The term *introspection* is sometimes used very broadly to cover nearly any first-person, nonconsciously inferential avenue to knowledge of what mental states we are in. But on a more restricted usage (one to be followed here), introspecting a mental state is supposed to be a kind of direct act of awareness of the state. According to introspectionism, we can attend to our current conscious

states by introspecting them (Locke 1690; Broad 1925; Armstrong 1963; Hill 1991; Lycan 1996; Macdonald 1998, 1999; McLaughlin 2000, 2001, 2003c; Sturgeon 2000; Goldman 2002). The term *introspection* derives from the Latin *spicere*, which means "look," and the Latin *intra*, which means "within." But the etymology is misleading. Introspectionists do not hold that we literally look within. There is no "mind's eye" by which we observe our visual experiences, no "mind's ear" or "mind's toe" by which we observe, respectively, our auditory experiences and tactile experiences.

It is widely held that we see the scenes before our eyes by having visual experiences caused by them. We are not, however, aware of our visual experiences by having visual experiences caused by them. We do not see our visual experiences; they do not look any way to us. (Nor do they look any way to an internal homunculus; an untenable view that leads to an infinite regress of sighted homunculi embedded within sighted homunculi.) Introspective access is direct in a way perceptual access is not. We experience our experiences, not by having experiences of them, but by having them. We can have them without introspecting them. But when we introspect, our attentional access to them is direct in that it is unmediated by any experiential states. Experiences are in that sense self-presenting (Chisholm 1977). If this view is correct, then we are immune to a certain kind of error. When our perceptual experiences are illusory, when things are not as they appear, we can be misled into believing that they are as they appear. If, however, our conscious states are self-presenting, then there is no appearance/reality distinction that pertains to them. We thus cannot be misled about them by their appearing to us some way that they are not.

Some introspectionists maintain that an act of introspective awareness of a conscious state is direct in yet another sense: it is unmediated by any causal mechanism. If, however, introspective awareness of a conscious state involves believing something of the state (for example, that it is a pain), the question arises as to whether this of-ness connection requires causation. It seems like mystery-mongering to maintain that it is a primitive, fundamental relation. One view is that the relation is part-whole rather than causal: The conscious state is a constituent of the introspective belief. But there are constituents of the belief that the belief bears no of-ness relation to, for example, the concepts involved in it. So, the constituency must be of a special sort. Proponents of this view are under an obligation to explicate it. There is also the issue of whether such an account can allow for mistaken intro-

spective beliefs. These remain topics of investigation (see Chalmers 2003).

The more common view is that an introspective belief and the state introspected are linked by a causal mechanism. Causes and effects, however, must be “distinct existences,” and so capable of independent existence (Armstrong 1963). This causal view thus seems to entail that there could be a being with beliefs that it is in conscious states of various sorts on various occasions yet is never in such states. But perhaps there could be a silicon-based robot that is such a being—possessed of the relevant concepts but entirely devoid of sentience (McLaughlin and Tye 2003b). The shock of such a possibility is somewhat lessened if primary possession of concepts of conscious states requires acquaintance with such states (Peacocke 1998), so that the robot could possess them only in a secondary way—by communicative interaction with conscious beings that possess them in a primary way.

Another “independent existence” concern with the causal view is that it entails the possibility of beings who are in conscious states but lack the capacity to be introspectively aware of them, and so who are “self-blind” with respect to them (Shoemaker 1984b, 1984c). Introspectionists, however, maintain that introspective awareness of a conscious state consists of a belief that one is in the state, a belief formed by direct acquaintance with the state. Animals seem self-blind in the sense in question: they do not form beliefs about what conscious states they are in, for they lack the requisite concepts to do so. Indeed, animals do not introspect their conscious states; they are conscious, but not self-conscious. So, this sort of self-blindness may seem not to count against introspectionism. Nevertheless, there is a sense in which animals are aware of their pains or itches, for instance; that is why the dog yelps or scratches. Indeed it seems that their attention might be riveted on their sensation. It remains an open question whether the relevant mode of attention can be captured by a model of introspective attention as belief-formation or whether further distinctions are called for.

It has been claimed that when we try to direct our attention to our visual experience in order to introspect it, we seem to find ourselves only inspecting the scene before our eyes (Moore 1903; Harman 1990, Dretske 1994, 1999; Sturgeon 2000; Tye 2000). It is thus claimed that visual experience is phenomenologically “transparent” or “diaphanous.” And some philosophers claim that all conscious states are diaphanous (Tye 2000). The phenomenological thesis of transparency seems most plausi-

ble for visual experiences and least plausible for bodily sensations. But it is maintained that even when we attend to a toothache, our attention seems focused on a feature of the tooth itself, however alarming we may find that feature.

In the light of these phenomenological considerations, a “displaced-perception model” of first-person knowledge of experience has been proposed (Dretske 1994, 1999; Tye 2000). The leading idea in the visual case is this: when we are attentively aware that we are having a visual experience, our “awareness-that” is not based on direct awareness of the experience but rather on awareness of the scene before our eyes. Our awareness of the experience is indirect, because we are aware of it by being aware of the scene. Nevertheless, if we have mastered the concept of visual experience, we can come to be aware that we are having a certain visual experience, without recourse to consciously drawing inferences.

Hallucination seems to pose no problem for the phenomenological transparency thesis itself: Perhaps, whenever we visually hallucinate, we seem to be aware only of a scene. But hallucination poses a problem for the displaced-perception model if, when we (completely) hallucinate, we are not actually aware of any scene at all. If there are sense data (Ayer 1940), then we will actually be aware of a scene, even when we completely hallucinate, for sense data would constitute a scene. But the leading proponents of the displaced-perception model are physicalists and so deny that there are sense data. Proponents of the model have tried to accommodate hallucination by maintaining that in such a case one is aware of a type of scene, despite not being aware of any actual instance of it. Whether this model applies to visual experience and all conscious states remains a topic of controversy.

Our ordinary epistemic practices seem to rely not only on the presumption that our (sincere) first-person ascriptions of conscious states (for example, ‘I am in pain’) are *prima facie* true but also on the presumption that our first-person ascriptions of beliefs (for example, “I believe that P”), desires, and intentions are *prima facie* true. It has been claimed that the social-psychological data about confabulation shows the latter presumption to be unfounded. But, arguably, the data seem to show only that we have a tendency to confabulate when under pressure to explain how we arrived at our propositional attitudes or made choices; thus the data seems not to raise an unanswerable challenge to first-person authority. In any case, many contemporary philosophers claim that whatever role introspection may play in explaining our first-person authority as self-ascribers of conscious states, it

has little to do with our first-person authority concerning our propositional attitudes (Davidson 1984, 1986; Gallois 1996; Moran 2001).

Even if we indeed introspect conscious states (as these were characterized earlier), we do not introspect our beliefs, desires, or intentions. Indeed, we do not even introspect our attitudinal emotions (fear that *P*, anger that *Q*, relief that *R*, and so on). Such states can count as conscious, but only in the sense that they can have characteristic manifestations in consciousness; and (at best) we introspect only conscious states that manifest them. Thus, we may introspect an impulse, but not a desire; a feeling of anger, but not an attitude of anger; a thought that *P*, but not a belief that *P*. Indeed, to be aware of one's belief that *P* is just to be aware that one believes that *P*; and similarly for the other cases (Shoemaker 1994b). Just as we can typically know what we believe without observing our behavior, we can typically know what we believe without introspecting.

Moreover, although we sometimes know that we believe something as a result of assessing evidence that we do, such a case seems atypical. When we ask ourselves whether we believe that *P*, want *X*, or intend to *A*, we usually do not reflect on evidence concerning whether we believe that *P*, want *X*, or intend to *A*. Of course, we sometimes do that. But in response to the questions we typically reflect, respectively, on whether *P*, whether *X* has some attractive feature, and whether we ought to do *A* (Evans 1981, Gallois 1996, Moran 2001). Although we typically do that, reasons for believing that *P* is true are not reasons for believing that one believes that *P*; and reasons for believing that one ought to *A* are not reasons for believing that one intends to *A* (similarly for the desire case). Rather, they are, respectively, reasons to believe that *P* and reasons to intend to do *A*. So, the question of how such reflection leads to knowledge of our beliefs, desires, and intentions persists.

Philosophers who seek a role for introspection here will claim that, when we engage in such deliberative reflective reasoning, we can be introspectively aware of our occurrent thoughts. Philosophers who reject any role for introspection here will claim that even if we can indeed introspectively observe manifestations of propositional attitudes in consciousness and so have more "observational data" than others who can only observe manifestations of our attitudes in our overt verbal and nonverbal behavior, the fact that we have such additional observational data will not explain our first-person authority about our attitudes. Moreover, occurrently thinking that *P* is a mental act—indeed a basic mental

act: something we do, but not by doing something else (Moran 2001). Our knowledge of what we are occurrently thinking is knowledge of something that we are doing. Our distinctively characteristic knowledge of our basic actions may not be introspective. What explains first-person authority about our propositional attitudes and basic actions remains an open issue.

Many philosophers have related first-person authority about attitudes and actions to the fact that attitudes and actions (unlike bodily sensations, imagery, or sense experiences) can be rational or irrational. One view is that our practice of attributing propositional attitudes is essentially an interpretive practice governed (in part) by constitutive principles of rationality, and the presumption of first-person authority is required for interpretation to be possible (Davidson 1984, 1986). Another view is that the functional organization required to be a rational agent guarantees that a rational agent will, for the most part, be reliable in his or her beliefs about what propositional attitudes and experiences he or she has (Shoemaker 1994a, 1994b, 1994c). Yet another view seeks to explain our first-person authority in terms of rational commitment and first-person deliberation (Moran 2001). There are other very influential views (Burge 1988, 1993).

Belief, desire, intention, and occurrent thought are modes of intentionality; states of these (and other intentional) types have representational content. One issue is how one knows which of these (or other intentional) types a given intentional state falls under; another issue is how one knows what the content of the state is. Thus, there is, for instance, the issue of how one knows that one's belief that *P* is a belief (rather, than, say, a desire); and there is the issue of how one knows that one's belief is a belief that *P* (rather than a belief that something else is the case).

The leading contemporary theories of mental content are externalist theories, according to which the content of a mental state fails to supervene on intrinsic states of the subject (Putnam 1975, Burge 1979). On these views, two intrinsic duplicates (for example, an inhabitant of Earth and her doppelgänger on Twin Earth) could be in mental states with different contents. Some externalist theories hold that content depends on historical context (Dretske 1988), and according to others, it depends on social context (Burge 1979). There has been extensive debate about whether content externalism is compatible with our having first-person authority or privileged first-person knowledge concerning what we think. Some philosophers argue for incompatibilism (for

example, Boghossian 1989, 1997; McKinsey 1991). Some argue for compatibilism (for example, Davidson 1984, 1986; Burge 1988, 1993; Brucekner 1992; Heil 1992; Gallois 1996; Peacock 1998; Davies 1998; Gibbons 1996; Falvey and Owens 1994; McLaughlin and Tye 1998a, 1998b; McLaughlin 2000, 2003a; Brown 2004).

Here is an example of one of the leading incompatibilist lines of argument (McKinsey 1991, Boghossian 1997). For any of the content-externalists theories in question, there will be some contingent environmental proposition E such that E can be known only on the basis of empirical evidence, yet the theory will entail that it is a conceptual truth that if we are thinking that P, then E. Thus, if we could have privileged first-person knowledge that we are thinking that P, it follows that we would be able to infer that E and thereby come to know it on some basis other than empirical evidence. Some compatibilists have responded that the relevant contingent environmental propositions will be ones that can thereby be known on a basis other than empirical evidence, however surprising that might be (Warfield 1998, Sawyer 1998). But by far the more prevalent compatibilist response is to try to show that combinations of the relevant content-externalist and privileged self-knowledge theses do not lead to this result (Brueckner 1992; Davies 1998; McLaughlin and Tye 1998a, 1998b; 2003a).

SELF-PREDICTION

In recent years philosophers have produced arguments designed to prove that not all human behavior can be predicted or otherwise known in advance, and these arguments have been taken to be relevant to the problem of freedom of the will as well as to the question whether there can be genuine behavioral sciences. Specifically, it is argued that in certain circumstances it is logically impossible that one should come to know decisions, and actions for whose occurrence decisions are necessary conditions, in advance of the occurrence of such decisions. This has been interpreted as a refutation of determinism.

Two antipredictive arguments will be presented separately, and later their import when taken together will be discussed. The first concerns the scientific defectiveness of predictions that influence the predicted event, and the second concerns the logical impossibility of a person's knowing now what he will decide only at some future time.

INFLUENCE OF PREDICTIONS

It is a familiar fact that some prophecies and predictions are self-fulfilling in the sense that the prediction itself produces the predicted event—for example, when all the stock market tip sheets predict that stock *x* will drop sharply in the next few weeks. We also know, for similar reasons, that some predictions are self-defeating. For example, Jones predicts that he will, as usual, take the easy way out of a difficulty, but then, to prove to himself that he can do better, he does just the opposite. This prediction affected his deliberation and caused him to make a decision opposite to the one he had predicted. Now, the argument that follows does not maintain that a person's predictions of his own future decisions are necessarily or always self-defeating; instead, it maintains that it is logically impossible that by considering causes a person

should come to know that his final prediction of what he will decide is not self-defeating, and it maintains that the attempt to achieve such knowledge involves an infinite regress. In other words, this antipredictive argument purports to prove that predictions of one's own future decisions on the basis of antecedent causal conditions cannot possibly be scientifically complete.

It is necessary to state some assumptions and restrictions required by the argument. The first assumption is that decisions are events and hence are the sorts of things that can be caused; many philosophers would reject this assumption. Second, the argument concerns only causal knowledge of future decisions, by which is meant predictions derived with scientific adequacy from what one knows to be all the relevant antecedent causes of the decision, as distinct from predictions not known to be based on all the relevant causes and which consequently yield only a likelihood of the decision's occurrence. Finally, the argument aims to prove only that it is logically impossible for a person to have causal knowledge of his own decision in advance of making such a decision.

Let us assume, then, that some set of circumstances *C* is causally sufficient for a person *S* to make decision *D* and that *S* has unlimited knowledge of past circumstances and relevant causal laws. Can *S* come to know that *C* is sufficient for *D*? *S* may come to make a prediction *P* that past circumstances *C* are sufficient for *D*. We have supposed that as a matter of fact *C* is causally sufficient for *D*, but *S* nevertheless cannot know that this is so unless he also knows that there are no contrary causes. That is, before *S* can know that *C* is sufficient for *D* he must also know that there is no other circumstance which, together with *C*, is sufficient for not-*D*. One such probable cause of not-*D* is the prediction itself. Therefore, *S* cannot know that *C* is sufficient for *D* unless he knows that it is false that

(1) *C* plus *P* are causally sufficient for not-*D*.

S has been allowed unlimited knowledge of past circumstances and relevant causal laws, hence *S* can know that (1) is false, that is, he can know that making the prediction will not cause him to make a different decision. It does not follow, however, that *S* now can know that *C* is sufficient for *D*, for the same problem recurs: *S*'s knowledge that (1) is false, which we will call *P*₁, is a new datum and is itself a possible cause of not-*D*. Therefore, *S* cannot know that *C* is sufficient for *D* unless he knows that it is false that

(2) *C* plus *P*₁ are causally sufficient for not-*D*.

And *S*'s knowledge that (2) is false, or this knowledge plus his feelings or attitudes toward (2), constitute a further possible contrary cause, *P*₂. Thus, an infinite regress arises, within which the agent's prediction on the basis of some evidence *C* or his revision of the prediction or his final thoughts about the prediction are relevant data in addition to the data upon which the prediction was based. *S*'s calculating of causes cannot possibly "catch up" with the number of possible causes that must be examined if the prediction is to be scientifically complete, for the final results obtained cannot themselves also be part of the basis of one's prediction.

When one attempts to predict a supernova, it is true that in this case, too, the final prediction arrived at is necessarily excluded from the data upon which the prediction is based. However, although it is logically possible that predictions or thoughts about predictions can produce or impede a supernova, it is not scientifically possible that they do so. Therefore, the infinite regress argument is no obstacle to knowledge of, for example, scientific laws or stellar events but concerns only particular events that can be produced or prevented by human agency. And it is clearly applicable to attempted predictions of one's own decisions because we know that speculations and predictions about what one is likely to decide are always among the conditions most likely to be determinative of what one will in fact decide.

COUNTERARGUMENTS FAVORING DETERMINISM.

The view that this first antipredictive argument casts doubt on determinism may be challenged in a number of ways:

(a) The argument presents no obstacle to the existence of a complete causal explanation of one's own past decisions.

(b) There is no logical obstacle to a person's predicting a future decision of someone other than himself, although such prediction does confront a methodological difficulty. That is, suppose that *A* predicts a future decision of *B*'s and resolves not to tell *B* the prediction. Then it appears that *A* must also predict something about himself; namely, that he will not later decide to revoke his past decision and tell *B*, after all—and this, according to the infinite regress argument, *A* cannot possibly do. One complication here is the question whether the regress argument precludes *A*'s predicting that he will make no decisions at all during a certain future period; if the regress argument does not preclude this, then *A* can predict that he will not change his mind and tell the original prediction to *B*. But in any case the solution seems to lie in

having *A* make his prediction of *B*'s decision from a dungeon or a distant planet or in such a way that he has no time to communicate with *B* in advance of *B*'s making his decision; that is, perhaps it is sufficient that it be physically (although not logically) impossible that *A* should ruin the impeccable scientific basis of his prediction by telling *B*.

(c) The regress argument shows no peculiarity of human or even of sentient beings. For it is easy to imagine a simple machine, for which no one would dream of claiming free will or moral responsibility, the behavior of which could not possibly be predicted in circumstances similar to those previously described. We need only suppose that the machine can do two things, *x* and *y*, that a prediction of either of these things, punched into a card, can be inserted in the machine, and that we announce our predictions of what the machine will do by inserting appropriately punched cards into the machine. The machine is built to do *x* when fed the prediction "machine will do *y*" and to do *y* when fed the prediction "machine will do *x*." The situation in which a prediction of a person's decision is defective is fully as artificial as this, and in each situation the prediction is defective for the same reason. In each case, given the causal hypothesis, one can in principle make a scientifically impeccable prediction of what will occur only if neither the person nor the machine is allowed to be influenced by the prediction. Meaning "*y*" when one inserts the card saying "machine will do *x*" into the machine is equivalent to telling a person he will decide not-*D* when one knows that telling him this will cause him to decide *D*.

It can be argued that the first antipredictive argument shows only that given the causal hypothesis, it is still possible to make predictions competently and incompetently and that one of countless ways in which one can make predictions incompetently is to allow one's prediction to disturb the system that one is trying to predict. However, although it may be the case that the self-defeating prophecy and the self-fulfilling prophecy are equally explicable and, in general, equally avoidable phenomena, it appears that the special situation in which the self-defeating prophecy is unavoidable is important to us—namely, the situation in which we attempt to predict our own decisions. The regress argument also poses a methodological problem for social scientists who wish to circulate predictions of human behavior, but it does not show that there is any event that in principle cannot be predicted.

LOGICAL IMPOSSIBILITY OF SELF-PREDICTION

The second antipredictive argument appears to follow from the analytic truth that one cannot know now what, by hypothesis, one will not know until some later time. Thus, one form of this argument (see Karl Popper, "Postscript: After Twenty Years") maintains that exact historical prophecy is incompatible with the fact of advancing knowledge. That is, it is impossible to predict the future decisions and actions of people because these future decisions and actions will be formed and done on the basis of knowledge that, by hypothesis, no one now possesses.

Another form of the argument maintains that it is logically impossible for a person to know what he will decide to do before he actually makes his decision (see Stuart Hampshire, *Thought and Action*; Carl Ginet, "Can the Will Be Caused?"; and D. F. Pears, *Freedom and the Will*). It is claimed that if a person knows or thinks he knows what he will try to do tomorrow, then either he has already decided what he will try to do or he believes that what he will try to do is not up to him. In neither of these two cases can he decide what he will try to do, for in each case there is nothing for him to decide. Decision is making up one's mind about what one will try to do or about what one will acquiesce in; therefore, to say that one will decide tomorrow appears to entail that there is something one will know then and which, by hypothesis, one does not know now.

However, there is a difficulty here. What is it that one knows as a result of decision and that one cannot know prior to the decision? From the fact that a person has decided to do something, it does not follow that he knows what he will do or try to do in the future. Decision does not give one knowledge of anything that will occur in the future because the mere fact that a person has decided does not ensure that he will not falter, change his mind, or die tomorrow. Hence, it appears to be mistaken to assume that because decision entails ignorance prior to decision, this ignorance is of something which one will know later as a result of decision; what one comes to know when one decides is nothing in addition to the decision itself and not any fact about the future. The reason for this appears to be that "decision" is an intentional concept.

Sometimes a person claims to know what a future decision of his will be, and various explanations of his supposed mistake can be made: (a) He has already decided, and he confuses with the act of decision itself some future reaffirmation, announcement, or implementation of his decision. (b) He has tentatively decided and plans at the last moment to reappraise his decision, but he

thinks that he knows the result of that reappraisal because of his tentative decision. In this case, if he does not deliberate again at the last moment, then he merely reaffirms what he has already decided, and if he does deliberate again, then it is impossible that he should know in advance the result of his deliberation, even though this new decision agrees with his earlier tentative decision. (c) He construes a future reaffirmation of a decision already made to be a new decision because its time, place, or context differs from that in which he first decided. (d) He confuses a guess, likelihood, or probability with knowledge of his future decision.

It has also been claimed (for example, by Richard Taylor, in “Deliberation and Foreknowledge”) that if a person knows or thinks he knows what he will do in the future, then it is impossible for him to deliberate about what he will do, for deliberation also presupposes ignorance. “Jones is deliberating whether to do *x*” entails “Jones does not know whether or not he will do *x*.” But here a distinction must be made between the agent’s belief or knowledge that he will do a particular act in the future and the agent’s belief or knowledge that this particular act he will do is in some sense not up to him. If a person believes that he will do *x*, he cannot deliberate whether to do *x*, even though he believes that he will do *x* freely, that what he does is up to him. On the other hand, if a person believes that what he will do is not up to him, then he cannot deliberate whether to do *x*, even though he lacks knowledge or belief about what he will do. Hence, although it has been claimed that both foreknowledge and lack of freedom preclude deliberation and decision, these claims nevertheless require separate argument, and only foreknowledge is relevant to self-prediction and the paradoxes thereof.

It might be thought that the two antipredictive arguments are not truly distinct, and indeed some philosophers have written as though these arguments were but two approaches to the same logical point. But they are distinct, except insofar as they can be put to similar purposes. The first argument applies to all predictions that can causally influence the events predicted, whether these events happen to be decisions, revolutions, or stock market trends. It is thus broader in scope and does not require that the event also be of that special sort which, in certain circumstances, is logically impossible to know in advance. The second argument attacks the very idea of foreknowledge, however obtained, of occurrences that entail prior ignorance and does not, as does the first argument, attack the scientific adequacy of predictions that can influence the predicted events.

LOGICAL IMPOSSIBILITY OF CAUSING DECISIONS

Many philosophers would maintain that if some set of antecedent conditions is causally sufficient for the occurrence of an event, then it is logically possible that the event be predicted or known prior to its occurrence. From this claim, together with the second antipredictive argument, can be constructed the following argument that attempts to prove that it is logically impossible that decisions have causes (see Ginet, *op. cit.*): If it is logically possible for a decision to be caused, then it is logically possible for a person to know what his own decision will be before he makes his decision; it is not logically possible for a person to know what his own decision will be before he makes his decision; therefore, it is not logically possible for a decision to be caused.

This argument is, in the following way, of more apparent relevance to the traditional problem of freedom of the will and in particular to a theory of human agency: Let us suppose that decisions are necessary conditions for the occurrence of certain actions, and let us suppose further that decisions are part of the causes of such actions. If so, then any set of causes sufficient for the occurrence of such an action must include a decision as part of the set, for whatever is sufficient for something to occur must include everything necessary for that thing to occur. But the decision, by the preceding argument, is uncaused, and therefore no set of causes existing prior in time to the decision can be sufficient for the occurrence of the action. The decision can thus be viewed as a partial, uncaused cause of the action, which, together with ordinary causes, is sufficient for the occurrence of the action.

Difficulties of the following sort have been raised against the argument that maintains that it is impossible that decisions be caused: First, it has been doubted that it follows from the causal hypothesis that it is possible for a person to predict his own decisions; for the possibility of predictability in principle need not include the possibility of predictability in all possible circumstances (see A. J. Stenner, “On Predicting Our Future”). As we have seen, it is not obvious that paradoxes arise when we suppose someone to predict decisions of persons other than himself. Second, a premise of this argument maintains that from the hypothesis that decisions are caused, it follows that one could in principle make a scientifically adequate prediction, based on knowledge of antecedent causes, of one’s own future decision. But the first of the two antipredictive arguments claims that this does not follow at all, because it is impossible to establish that one’s prediction has no contrary influence on the predicted event.

That is, the first antipredictive argument, if sound, shows that the causal hypothesis does not entail the apparent absurdity that in principle one could, by considering antecedent conditions and relevant causal laws, come to know one's own decisions in advance.

SELLARS, ROY WOOD

(1880–1973)

Roy Wood Sellars, the American critical realist, taught philosophy at the University of Michigan. Although he was never as well known outside philosophical circles as some of his contemporaries, after the publication of his first book, *Critical Realism*, in 1916, Sellars maintained a substantial reputation among his fellow philosophers as a vigorously independent thinker. His thought was rigorous and critical; he never yielded to the fashionable movements of the day but steadfastly pursued his own original insights into basic philosophical problems.

The core of Sellars's philosophy is epistemological. He is concerned with showing that the critical realism of the philosopher is related to the "natural realism" of the "plain man." The philosopher reflects on the plain man's uncritical view of knowledge, which he clarifies and refines so that it is philosophically justifiable, but he does not vitiate its essential insistence upon the independence of the object of knowledge. The most significant element in Sellars's vindication of realism is his revision of the theory of perception, which he describes as a process of interpretation of *sensa*, as mediated by factors both external and internal to the perceiving subject. This view of perception avoids both the simplistic claim of natural realism that things reveal themselves directly in perception and the subjectivist claim that the objects of perception are ideas rather than things. Knowledge, too, is a complex process and occurs at various levels of complication. Its ultimate biological source is to be found in the adjustment of the organism to its environment; its ultimate outreach is in scientific knowledge, which replaces the relativity of individual perspectives by close approximations to exact measurement. Whether on the implicit organic level or on the highly explicit and self-critical scientific level, we know that we know when the content of our beliefs corresponds to the externally observed state of affairs.

Working from this epistemological position, Sellars developed an evolutionary cosmology and a materialistic ontology, carrying on his insight that there are levels, or "gradients," of being. Even the higher levels like life and mind, which emerge under most favorable conditions, are, however, physical systems. Sellars's materialism is nonreductive, but he insists that "life is not a nonnatural force coming from outside, but a term for the new capacities of which nature has found itself capable." On the valuational side, Sellars argues from these positions to a humanistic theory of ethics and religion (he was one of

the major contributors to the composition of the Humanist Manifesto of 1933) and to a politics of democratic socialism.

SELLARS, WILFRID

(1912–1989)

Wilfrid Stalker Sellars, an American philosopher and teacher, was born in Ann Arbor, Michigan, the son of Roy Wood Sellars, the American critical realist who taught at the University of Michigan. Wilfrid Sellars's early education took place in the United States and in France, where he attended the lycées Montaigne and Louis le Grand; it was continued at the University of Michigan (BA, 1933), the University of Buffalo (MA, 1934), and Oxford University, where he was a Rhodes scholar and received a BA with first-class honors in philosophy, politics, and eco-

nomics. He received an MA from Oxford in 1940. After a year at Harvard University he began his career as a teacher of philosophy in 1938 at the University of Iowa. During the war he spent several years as an officer in the Naval Reserve, and in 1946 he went to the University of Minnesota, where he eventually became professor of philosophy, chairman of the philosophy department, founding co-editor of the journal *Philosophical Studies*, and a member of Herbert Feigl's Minnesota Center for the Philosophy of Science. In 1959 he joined the faculty of Yale University, and in 1963 he moved to the University of Pittsburgh, where he became University Professor of Philosophy and Research Professor of the Philosophy of Science. Apart from numerous interludes as a visiting professor at other institutions, he remained at Pittsburgh until his death.

Although Sellars became an extremely prolific writer, in the early years of his career he had great difficulty putting his ideas on paper. His first scholarly essay, third in his list of publications, was "Realism and the New Way of Words"; it underwent seventeen major revisions, Sellars said in his "Autobiographical Reflections" (1975), before it finally appeared in print. In spite of its striking originality, his early work was strongly influenced by the logical empiricist movement, particularly by the work of Rudolf Carnap; in one essay, "Epistemology and the New Way of Words," he declared that philosophy "is properly conceived as the pure theory of empirically meaningful languages." From the vantage point of the early twenty-first century, perhaps the most significant of his early essays would be "Concepts as Involving Laws and Inconceivable without Them" (1948) and "A Semantical Solution of the Mind–Body Problem" (1953). Both show him to have been well ahead of his time in analytic philosophy. In the former he offered a clarification of necessity and natural law that anticipated the treatment of these notions in recent possible-world semantics, and in the latter he developed a distinctly functionalist view of intentional states. (The early essays discussed here are included in the volume *Pure Pragmatics and Possible Worlds: The Early Essays of Wilfrid Sellars*, edited by J. F. Sicha.)

Sellars's best-known philosophical work is the lengthy essay "Empiricism and the Philosophy of Mind," included in Sellars' *Science, Perception, and Reality*. This essay originated in lectures that Sellars gave in 1956 attacking what he called "the myth of the given." The cluster of ideas making up this doctrine was, he thought, the source of important errors in both the theory of knowledge and the philosophy of mind; by exposing the doc-

trine as a myth, he hoped to lay the groundwork for an acceptable form of empiricism and for a proper understanding of mental and sensory phenomena. The basic epistemic error prompted by the myth was the idea that empirical knowledge rests on a foundation of certain truth that is simply given to the mind—that is, knowable without inference—and provides the ultimate evidence for anything knowable by inference. The root error in the philosophy of mind prompted by the myth was the conviction that, merely by having sensory experiences and conscious thoughts, people gain theoretically satisfactory conceptions of those experiences and thoughts. These corresponding errors are related by the belief, commonly held by those who accept the myth, that foundational empirical knowledge concerns the sensory and psychological items, the mere having of which supposedly results in their being adequately conceived of or understood.

In attacking the errors he saw in the myth Sellars defended the view that empirical knowledge cannot have a foundation—that the supposedly basic knowledge of psychological fact presumed by the myth cannot exist independently of general knowledge relating psychological experience to linguistic and other behavior—and that theoretically adequate conceptions of anything can be obtained only by a process of learning and can be known to be adequate only by reference to scientific theorizing about the sensory and cognitive capabilities of human beings. He argued that “empirical knowledge ... is rational not because it has a *foundation* but because it is a self-correcting enterprise which can put *any* claim in jeopardy, though not *all* at once” (1991, pp. 127–196). As for commonsense sensory and psychological concepts, he argued that it is illuminating to think of them as resulting from an attempt to explain intelligent, nonhabitual human behavior by postulating appropriate “inner episodes” in substantially the way that theoretical scientists explain facts about observable objects by postulating unobservable microcauses. In arguing this point he added that, when concepts of such inner episodes are developed, people can learn to use them in making first-person reports of what they are experiencing. Seen this way, psychological concepts are fundamentally intersubjective rather than private, and they are as subject to revision as any concept of theoretical science.

In “Philosophy and the Scientific Image of Man” (1960), also included in *Science, Perception, and Reality*, Sellars developed the thesis that, although theoretical science is a natural development of commonsense thought about the world, it is not evidentially dependent upon it.

Like David Hume, Sellars thought that scientific thinking yields a theoretical picture of humans in the world that is incompatible with the commonsense—or, as he called it, the “manifest”—image of the same reality. These clashing images are not on a par, he thought; in purely descriptive respects, the scientific image is an improvement upon the manifest image, containing “successor concepts” to commonsense counterparts. (Water, on this view, is not identical with H₂O; the technical concept of H₂O applies to a common ingredient in most puddles, wells, clouds, and seas—one that is not accurately singled out by any commonsense concept.) A philosophically adequate picture of humans in the world is not fully descriptive, however; it is partly normative. Working out such a picture is an important philosophical task that has yet to be accomplished: the scientific image is not yet complete, and serious problems exist about how some normative matters can be incorporated into a significantly different image.

In later writings Sellars worked out highly original ideas on most central fields of philosophy. He produced, as Johanna Seibt (1990) observed, a unique scheme of “full scope nominalism,” which purports to demonstrate the expendability of abstract entities for all their supposed explanatory functions; he worked out (he was the first to do so) a sophisticated “conceptual role” semantics: he developed a neo-Kantian view of moral obligation and the moral point of view; and he had original things to say about central figures and issues in the history of philosophy. At a time when systematic philosophy was decidedly out of fashion, Sellars pursued the synoptic vision of humans in the world that Plato spoke of in the Republic. In parody of Kant he liked to tell his students that in philosophy analysis without synthesis must be blind.

SEMANTICS

Semantics is the study of meaning. More specifically, semantics is concerned with the systematic assignment of meanings to the simple and complex expressions of a language. The best way to understand the field of semantics is to appreciate its development through the twentieth century. In what follows, that development is described. As will be seen, advances in semantics have been intimately tied to developments in logic and philosophical logic.

Though there were certainly important theories, or proto-theories, of the meanings of linguistic expressions prior to the seminal work of the mathematician and philosopher Gottlob Frege, in explaining what semantics is it is reasonable to begin with Frege's mature work. For Frege's work so altered the way language, meaning and logic are thought about that it is only a slight exaggeration to say that work prior to Frege has been rendered more or less irrelevant to how these things are currently understood.

In his pioneering work in logic *Begriffsschrift, eine der arithmetischen nachgebildete Formalsprache des reinen Denkens*, which was published in 1879, Frege literally revolutionized the field. It is well beyond the scope of the present entry to describe Frege's achievements in this work. But it should be said that one of his most important contributions was to achieve for the first time a clear understanding of the semantic functioning of expressions of generality, such as 'every,' 'some' and so on. This made it possible to understand, again for the first time, how sentences containing multiple expressions of generality, such as 'Every skier loves some mountain,' manage to mean what they do. In a series of papers written in the late 1800s, Frege articulated a novel theory of meaning for languages that was to be very influential. These papers

included "Function and Concept" (1891), "On Concept and Object" (1892) and most famously "On Sense and Reference" (1892).

Frege made a fundamental distinction between expressions that are *unsaturated* or *incomplete* and expressions that are *complete*. The former he called *concept words* (perhaps *concept expressions* would be better) and the latter he called *proper names*. A sentence like:

1. Frege runs.

can be split up into the part that is unsaturated, the concept word 'runs,' and the complete part, the proper name 'Frege.' All expressions, Frege thought, are associated with a *sense* and a *reference*. These both have some claim to be called *the meaning* of the expression in question, and so it is probably best to think of Frege as claiming that there are two components to the meaning of an expression. The referent of an expression can be thought of as the thing in the world the expression stands for. Thus, the referent of the proper name 'Frege' is Frege himself. And the referent of the concept word 'runs' is a *concept*, which Frege took to be a function from an object to a truth value. So the concept 'runs' refers to maps an object *o* to the truth value true iff *o* runs. Otherwise, it maps the object to false. By contrast the sense of an expression Frege thought of as a way or mode in which the referent of the expression is presented. So perhaps Frege can be "presented" as the author of *Begriffsschrift*. Then the sense of the name 'Frege' is the descriptive condition *the author of Begriffsschrift*. It is perhaps more difficult to think of senses of concept words, but it helps to think of them as descriptive conditions that present the concept that is the referent in a certain way.

Now Frege thought that the sense of an expression determines its referent. So the sense of 'Frege' is a mode of presentation of Frege, a descriptive condition that Frege uniquely satisfies in virtue of which he is the referent of 'Frege.' Further, in understanding a linguistic expression, a competent speaker grasps its sense and realizes that it is the sense of the expression.

Of course complex linguistic expressions, such as 1 above, also have senses and references. Frege held that the sense of a complex expression is determined by the senses of its parts and how those parts are combined. (Principles of this general sort are called *principles of compositionality*, and so it could be said that Frege held a principle of compositionality for senses.) Indeed, Frege seems to have held the stronger view that the sense of a complex expression is literally built out of the senses of its parts. In the case of 1, its sense is the result of combining the sense of

'runs' and of 'Frege.' Frege believed that just as the expression 'runs' is unsaturated, so its sense too must be unsaturated or in need of completion. The sense of 'Frege,' by contrast, like the expression itself, is whole and complete (not in need of saturation). The sense of 1 is the result of the whole sense of 'Frege' saturating or completing the incomplete/unsaturated sense of 'runs.' It is the unsaturated sense of 'runs' that holds the sense of 1 together, and this is true generally for Frege. Frege called the sense of a declarative sentence like 1 a *thought*. Thus in "On Concept and Object" (p. 193) Frege writes:

For not all the parts of a thought can be complete; at least one must be unsaturated or predicative; otherwise they would not hold together.

Similarly, Frege held that the reference of a complex expression is determined by the references of its parts and how they are put together (i.e. he held a principle of compositionality for referents). In the case of 1, the referent is determined by taking the object that is the referent of 'Frege' and making it the argument of the function that 'runs' refers to. This function maps objects to the True or the False depending on whether they run or not. Thus, the result of making this object the argument of this function is either the True or the False. And whichever of these is the result of making the object the argument of the function is the referent of 1. So sentences have thoughts as senses and truth values (the True; the False) as referents.

Concerning Frege's account of sentences containing *quantifiers*, expressions of generality such as 'every,' 'some' etc., consider the sentence

2. Every student runs.

The words 'student' and 'runs' are both concept words. Thus they have unsaturated senses and refer to concepts: functions from object to truth values. Now Frege thought that a word like 'every' was doubly unsaturated. To form a whole/complete expression from it, it needs to be supplemented with two concept words ('student' and 'runs' in 2). The sense of 'every' is also doubly unsaturated. Thus the sense of 2 is a thought, a complete sense, that is the result of the senses of 'student' and 'runs' both saturating the doubly unsaturated sense of 'every' (in a certain order). By contrast, the referent of 'every' must be something that takes two concepts (those referred to by 'student' and 'runs' in 2) and yields a referent for the sentence. But as we have seen, a sentence's referent is a truth value. Thus the referent of 'every' must take two concepts and return a truth value. That is, its referent is a function from a pair of concepts to a truth value. In

essence, 'every' refers to a function that maps the concepts A and B (in that order) to the True iff every object that A maps to the true, B maps to the true (i.e. iff every object that falls under A falls under B).

Above it was mentioned that Frege thought that the referent of a complex expression was a function of the referents of its parts and how they are combined (compositionality of reference). Some examples seem to show that this is incorrect. Consider the following:

3. Chris believes that snow is white.

3a. Chris believes that Mt. Whitney is more than 14,000 feet high.

These sentences may well have different referents, that is, truth values. But the embedded sentences ('snow is white'; 'Mt. Whitney is more than 14,000 feet high') have the same referents (the True) and the other parts of the sentences have the same referents as well. But then it would seem that compositionality of reference would require that 3 and 3a have the same reference/truth value. Frege famously gets out of this apparent problem by claiming that 'believes' has the effect of shifting the referents of expressions embedded with respect to it. In 3 and 3a, the shifted referents of the embedded sentences are their usual senses. So in these environments, the sentences have different referents because they express different thoughts outside of contexts involving 'believes' and related devices.

Frege's doctrine of sense and reference constitutes a semantical theory of languages, because it claims that the meanings of linguistic expressions have these two components, and it gives an account of what the senses and referents of different kinds of linguistic expressions are.

Shortly after Frege had worked out his semantical theory of sense and reference, the English philosopher and mathematician Bertrand Russell was working out a theory of the meanings, or information contents of sentences. While Frege had held that the thought expressed by a sentence, which captures the information the sentence encodes, consisted of senses, Russell (1903) held that the information encoded by sentences were *propositions*, where the constituents of propositions, far from being Fregean senses, where roughly (and for the most part) the things the propositions is about. Thus, whereas Frege held that 1 expressed a thought containing a mode of presentation of Frege and a mode of presentation of the concept of running, Russell held that the proposition expressed by 1 contained Frege himself and the concept of running (though Russell thought of concepts differently from the way Frege did). This contrast has more

than historical significance, because current semanticists are classified as Fregean or Russellian depending on whether they hold that the information contents of sentences contain the things those information contents are about (objects, properties and relations—Russellian) or modes of presentation of the things those information contents are about (Fregean).

In the early part of the twentieth century, the philosophical movement known as *Logical Positivism* achieved dominance, especially among logically minded philosophers who might have been interested in semantics. The Positivists thought that much of traditional philosophy was literally nonsense. They applied the (pejorative) term “*metaphysics*” to what they viewed as such philosophical nonsense. The Positivists, and especially Rudolf Carnap, developed accounts of meaning according to which much of what had been written by philosophers was literally meaningless. The earliest and crudest Positivist account of meaning was formulated by Carnap (1932). On this view, the meaning of a word was given by first specifying the simplest sentence in which it could occur (its *elementary sentence*). Next, it must be stated how the word’s elementary sentence could be verified. Any word not satisfying these two conditions was therefore meaningless. Carnap held that many words used in traditional philosophy failed to meet these conditions and so were meaningless.

Carnap called philosophical statements (sentences) that on analysis fail to be meaningful *pseudo-statements*. Some philosophical statements are pseudo-statements, according to Carnap, because they contain meaningless terms as just described. But Carnap thought that there is another class of philosophical pseudo-statements. These are statements that are literally not well formed (Carnap gives Heidegger’s “We know the nothing.” as an example).

The downfall of the Positivist’s theory of meaning was that it appeared to rule out certain scientifically important statements as meaningless. This was unacceptable to the Positivists themselves, who were self-consciously very scientifically minded. Carnap heroically altered and refined the Positivists account of meaningfulness, but difficulties remained. Hempel (1950) is a good source for these developments.

At about the same time Carnap was formulating the Positivists’ account of meaning, the Polish logician Alfred Tarski was involved in investigations that would change forever both logic and semantics. It had long been thought that meaning and truth were somehow intimately connected. Indeed, some remarks of Wittgenstein’s in his *Tractatus Logico-Philosophicus* (“4.024. To

understand a proposition means to know what is the case, if it is true.”) had led many to believe that the meaning of a sentence was given by the conditions under which it would be true and false. However, the Positivists had been wary of the notion of truth. It seemed to them a dangerously metaphysical notion, (which is why they “replaced” talk of *truth* with talk of *being verified*).

Against this background, Tarski showed that truth (‘true sentence’) could be rigorously defined for a variety of formal languages (languages, growing out of Frege’s work in logic, explicitly formulated for the purpose of pursuing research in logic or to be used to precisely express mathematical or scientific theories). Though earlier papers in Polish and German contained the essential ideas, it was Tarski (1935) that alerted the philosophical world to Tarski’s important new results.

Tarski himself despaired of giving a definition of *true sentence of English* (or any other naturally occurring language). He thought that the fact that such languages contain the means for talking about expressions of that very language and their semantic features (so English contains expressions like ‘true sentence,’ ‘denotes,’ ‘names,’ etc.) meant that paradoxes, such as the paradox of the liar, are formulable in such languages. In turn, Tarski thought that this meant that such languages were logically inconsistent and hence that there could be no correct definition of ‘true sentence’ for such languages.

Nonetheless, Tarski’s work made the notion of truth once again philosophically and scientifically respectable. And it introduced the idea that an important element, perhaps the sole element, in providing a semantics for a language was to provide a rigorous assignment to sentences of the language the conditions under which they are true. (Tarski’s 1935 paper for the most part gave definitions of *true sentence* for languages with fixed interpretations. The now more familiar notion of *true sentence with respect to a model* was introduced later. See Hodges [2001] for details.)

Carnap’s *Meaning and Necessity* (1947) is arguably the first work that contemporary semanticists would recognize as a work in what is now considered to be semantics. Following Tarski, Carnap distinguishes the languages under study and for which he gives a semantics, *object languages*, from the languages in which the semantics for the object languages are stated, *metalanguages*. The object languages Carnap primarily considers are a standard first order language (S_1), the result from adding ‘N’ (“a sign for logical necessity”) to that language (S_2), and ordinary English. Carnap does not give detailed descriptions of any of these languages, noting that the book

“... is intended not so much to carry out exact analyses of exactly constructed systems as to state informally some considerations aimed at the discovery of concepts and methods suitable for semantical analysis” (p. 8).

The heart of Carnap’s semantics for these languages is given by *rules of designation* for predicates and individual constants, *rules of truth* for sentences and *rules of ranges* for sentences. The rules of designation state the meanings of the predicates and individual constants using English as the metalanguage. So we have (p. 4):

‘s’ is a symbolic translation of ‘Walter Scott’
 ‘Bx’—‘x is a biped’

The rules of truth simply provide a Tarski style definition of truth for sentences of the language, (the definition assumes fixed meanings given by the rules of designation for predicates and individual constants). In order to specify the rules of range, Carnap introduces the notion of a *state-description*. For a language, say S_1 , a state description in S_1 is a set that contains for every atomic sentence of S_1 , either it or its negation, but not both; and it contains no other sentences. Carnap comments (p. 9):

... it [a state-description in S_1] obviously gives a complete description of a possible state of the universe of individuals with respect to all properties and relation S expressed by predicates of the system. Thus the state-descriptions represent Leibniz’ possible worlds or Wittgenstein’s possible states of affairs.

Next Carnap gives a recursive characterization of a *sentence holding in a state-description*. An atomic sentence holds in a state-description iff it is a member of it. A disjunction holds in it iff one of its disjuncts holds in it, etc. The characterization of *holding in a state description* is designed to formally capture the intuitive idea of the sentence being true if the possible world represented by the state-description obtained (i.e. if all the sentences belonging to the state-description were true). Given a sentence S, Carnap calls the class of state-descriptions in which S holds its *range*. Thus the clauses in the characterization of *holding in a state-description* Carnap calls *rules of ranges*. Regarding these rules of ranges, Carnap writes (p. 9–10):

By determining the ranges, they give, together with the rules of designation for the predicates and the individual constants ..., an *interpretation* for all sentences of S_1 , since to know the meaning of a sentence is to know in which of the possible cases it would be true and in which not, as Wittgenstein has pointed out.

Thus, Carnap regards the rules of ranges together with the rules of designation as giving the meaning of the sentences of S_1 (the connection with truth and the rules of truth is that there is one state-description that describes the actual world, and a sentence is true iff it holds in that state-description).

Using these resources, Carnap defines his well known *L concepts*. We here concentrate on *L-truth* and *L-equivalence*. Before getting to that, we must say something about Carnap’s notion of *explication*. Carnap believed that one of the main tasks for philosophers was to take a “vague or not quite exact” concept, and replace it by a more exact concept that one had clearly characterized. This new concept, called by Carnap the *explicatum* of the old concept, was intended to be used to do the work the old concept was used to do. Carnap thought that the notion of *L-truth* was the explicatum of the vague notions of “logical or necessary or analytic truth” (p. 10).

A sentence is L-true in a semantical system (e.g. S_1) iff it holds in every state description in that system. Carnap regarded this as a precise characterization of Leibniz’s idea that necessary or analytic or logical truths hold in all possible worlds. Next, Carnap defines the notion of *L-equivalence* for sentences, predicates and individual constants. Effectively, two names, predicates or sentences are L-equivalent (in a semantical system—e.g. S_1) iff they have the same extension at every state-description in that system, (so L-equivalent names must name the same individual at every state description, L-equivalent predicates must be true of the same individuals at every state description, etc.).

The importance of Carnap’s notion of *L-equivalence* is that he uses it to sketch a semantics for belief ascriptions. In order to do this, Carnap extends his notion of *L-equivalence* in several ways. First, he extends it so that expressions of different “semantical systems” (roughly, formal languages) may be L-equivalent (in effect, expressions e of system 1 and e' of system 2 are L-equivalent just in case the semantical rules of the two systems together suffice to show that the expressions have the same extension, p. 57). Second, he extends the notion of *L-equivalence* to apply to sentential connectives, variables (they are L-equivalent iff they have the same range of values) and to quantifiers (they are L-equivalent iff they are quantifiers of the same sort [universal, existential] whose variables are L-equivalent, p. 58). Third, he defines what it is for two expressions of the same or different semantical systems (again, roughly formal languages) to be *intensionally isomorphic*. Roughly, expressions are intensionally isomorphic just in case they are built up in the same

way out L-equivalent parts. With these tools in hand, Carnap writes (p. 61–62):

It seems that the sentence ‘John believes that D’ in S [a fragment of English—see p. 53] can be interpreted by the following semantical sentence:

15-1. ‘There is a sentence \mathfrak{S}_1 in the semantical system S' such that (a) \mathfrak{S}_1 is intensionally isomorphic to ‘D’ and (b) John is disposed to an affirmative response to \mathfrak{S}_1

Though Carnap’s semantics for belief ascriptions was criticized by Alonzo Church (1950), many philosophers were influenced by Carnap’s idea that the objects of belief are structured entities built up in the same way out of entities with the same intensions. See, for example, Lewis (1970).

The final important feature of *Meaning and Necessity* was its semantic treatment of modality. Carnap begins his discussion of modality by mentioning the work of C. I. Lewis (presumably he had in mind especially Lewis and Langford [1932]) in constructing various systems of modal logic. As mentioned above, Carnap considered as an object of semantical investigation a language that was the first order predicate logic (S_1) supplemented with the sign ‘N’ “for logical necessity.” He called the resulting language S_2 . Syntactically, prefixing ‘N’ to a matrix (either a sentence or a formula with free variables) results in a matrix. A detailed discussion of Carnap’s semantics for this modal language would go beyond the scope of the present entry. However, a couple points are worth making. First, if we just consider the case in which ‘N’ fronts a *sentence* (formula with no free variables) ϕ , to get the rules of range for S_2 we would simply add to the rules of range of S_1 the following:

N(ϕ) holds in every state-description if ϕ holds in every state description; otherwise N(ϕ) holds in no state-description.

This is a consequence of Carnap’s idea that ‘N’ is the sign for logical necessity, and the notion of L-truth is the explicatum of the vague notion of logical necessity. Thus a sentence fronted by ‘N’ should hold at a state description iff the sentence it embeds holds at every state-description. But then if the sentence fronted by ‘N’ holds at a state-description, it holds at every state-description. Thus, the above.

But of course since ‘N’ could front a matrix with free variables, one could then attach a quantifier to the result. Letting ‘.u.’ be a matrix containing the variable ‘u’ free, we get things like

(u)N(.u..)

That is, we get quantifying into the sign ‘N’ for logical necessity. However, Carnap’s treatment here results in the above being equivalent to (indeed, L-equivalent to)

N(u)(.u..).

The important point, however, is that Carnap had sketched a semantics for quantified modal logic.

Though virtually all of the crucial analyses and explications in *Meaning and Necessity* were eventually significantly modified or rejected (the explication of “logical necessity” by the notion of L-truth, understood in terms of holding at all state-descriptions; the treatment of ‘N’, the sign of “logical necessity”; and the semantics for belief ascriptions), the work was nonetheless very important in the development of semantics. It provided a glimpse of how to use techniques from logic to systematically assign semantic values to sentences of languages, and began the project of providing a rigorous semantics for recalcitrant constructions like sentences containing modal elements and verbs of propositional attitude.

In the 1950s and early 1960s Carnap’s ideas on the semantic treatment of modal logic were refined and improved upon. The result was the now familiar “Kripke style” semantics for modal logic. Kripke’s formulations will be discussed here, but it is important to understand that similar ideas were in the air (see Hintikka [1961], Kanger [1957], and Montague [1960a]). Though these works were in the first instance works in logic, as we will see, they had a profound effect on people who were beginning to think about formal semantics for natural languages.

We will concern ourselves with the specific formulations in Kripke (1963). What follows will be of necessity slightly technical. The reader who is not interested in such things can skip to the end of the technical discussion for informal remarks. Assume that we have a standard first order logic with sentential connectives $\sim, \&$ and \square (the first and third one-place, the second two-place), individual variables (with or without subscripts) x, y, z, \dots ; n -place predicates P^n, Q^n, \dots (0 place predicate letters are *propositional variables*), and universal quantifier (for any variable x_i , (x_i)). A *model structure* is a triple $\langle G, K, R \rangle$, where K is a set, $G \in K$ and R is a *reflexive relation* on K (i.e. for all $H \in K$, $H R H$). Intuitively, G is the “actual world” and the members of K are all the possible worlds. R is a relation between worlds and is usually now called the *accessibility relation*. Intuitively, if $H R H'$ (H' is accessible from H), then what is *true* in H' is *possible* in H .

Again intuitively, the worlds accessible from a given world are those that are possible relative to it.

Putting conditions on R gives one model structures appropriate to different modal logics. If R is merely reflexive, as required above, we get an M model structure. If R is reflexive and *transitive* (i.e. for any $H, H', H'' \in K$, if $H R H'$ and $H' R H''$, then $H R H''$), we get an $S4$ model structure. Finally, if R is reflexive, transitive and *symmetric* (i.e. for any $H, H' \in K$, if $H R H'$, then $H' R H$), we get an $S5$ model structure. (It should be recalled that for Carnap, state-descriptions, which represented possible worlds, were each accessible for every other—in effect because there was no accessibility relation between state-descriptions; thus translated into the present framework Carnap’s “models” would be $S5$ models. Also, in Kripke’s semantics, possible worlds (members of K) are primitive; in Carnap’s, of course, they are explicated as state descriptions.) A *quantificational model structure* is a model structure $\langle G, K, R \rangle$ together with a function ψ that assigns to every H in K a set of individuals: the *domain* of H . Intuitively this is the set of individuals existing in the possible world H . Of course, this allows different worlds (members of K) to have different domains of individuals. This formally captures the intuitive idea that some individuals that exist might not have, and that there might have been individuals that there aren’t.

Given a quantificational model structure, consider the set U which is the union of $\psi(H)$ for all H in K . Intuitively, this is the set of all possible individuals (i.e. the set U of individuals such that any individual in the domain of any world is in U). Then U^n is the set of all n -tuples whose elements are in U . A *quantificational model* on a quantificational model structure $\langle G, K, R \rangle$ is a function φ that maps a zero-place predicate and a member of K to T or F ; and for $n > 0$, an n -place predicate and a member of K to a subset of U^n . We extend φ by induction to assign truth values to all formula/world pairs *relative to a function assigning members of U to variables*:

1. *Propositional Variable*: Let f be a function assigning elements of U to all individual variables. Let P be a propositional variable. Then for any H in K , $\varphi(P, H) = T$ relative to f iff $\varphi(P, H) = T$; otherwise $\varphi(P, H) = F$ relative to f .

2. *Atomic*: Let f be as in 1. For any H in K , $\varphi(P^n x_1, \dots, x_n, H) = T$ relative to f iff $\langle f(x_1), \dots, f(x_n) \rangle \in \varphi(P^n, H)$; otherwise $\varphi(P^n x_1, \dots, x_n, H) = F$ relative to f .

(Note that 2 allows that an atomic formula can have a truth value at a world relative to an assignment to its variables, where some or all of its variables get assigned things

not in the domain of the world, since f assigns elements of U to free variables; and φ assigns subsets of U^n to P^n !)

3. *Truth functional connectives*: Let f be as in 1. Let A and B be formulae. For any H in K , $\varphi(A \& B, H) = T$ relative to f iff $\varphi(A, H) = T$ relative to f and $\varphi(B, H) = T$ relative to f ; otherwise $\varphi(A \& B, H) = F$ relative to f . (Similarly for \sim)

4. *Modal operator*: Let f be as in 1. Let A be a formula. $\varphi(\Box A, H) = T$ relative to f iff $\varphi(A, H') = T$ relative to f for all $H' \in K$ such that $H R H'$; otherwise $\varphi(\Box A, H) = F$ relative to f .

(Note that according to 4, whether a formula $\Box A$ is true at a world (relative to f) depends only on whether A is true at all worlds *accessible* from the original world.)

5. *Quantifier*: Let f be as in 1. Let $A(x, y_1, \dots, y_n)$ be a formula containing only the free variables x, y_1, \dots, y_n . For any H in K , and any function g (assigning elements of U to free variables), suppose $\varphi(A(x, y_1, \dots, y_n), H)$ relative to g is defined. Then $\varphi((\forall x) A(x, y_1, \dots, y_n), H) = T$ relative to f iff for every f' such that $f'(x) \in \psi(H)$ and f' differs from f at most in that $f'(x)$ is not $f(x)$, $\varphi(A(x, y_1, \dots, y_n), H) = T$ relative to f' ; otherwise, $\varphi((\forall x) A(x, y_1, \dots, y_n), H) = F$ relative to f .

(As Kripke notes, that in 5 we consider only functions f' such that $f'(x) \in \psi(H)$ means that quantifiers range over only the objects that exist at the world where the quantified sentence is being evaluated.)

Now having gone through Kripke’s semantics for quantified modal logic in some detail, let us step back and ask why it was important in terms of thinking of the semantics of natural language. People like Richard Montague, who we will discuss below, were clearly influenced in their thinking about the semantics of natural language by Kripke’s semantics for modal logic, (recall too that Montague [1960a] itself contained ideas related to Kripke’s). Since at least Carnap’s *Meaning and Necessity* (and perhaps before), philosophers had thought of sentences as semantically associated with *propositions* and of n -place predicates as semantically associated with n -place *relations* (properties being one-place relations). Further, they had thought of these propositions and relations as determining truth values and extensions for the sentences and predicates expressing them relative to a “possible world” (which, of course, Carnap represented by a state description).

Now in Montague (1960b), it is suggested that an n -place relation just is a function from possible worlds to a set of n -tuples (intuitively, the set of n -tuples whose ele-

ments stand in the relation in question from the standpoint of the world in question); and that a proposition just is a function from possible worlds to truth values. Generalizing these ideas leads straightforwardly to possible worlds semantics for natural languages discussed below. Further, Montague claims this way of understanding relations and propositions (which Montague calls *predicates*, one-place predicates, then, are properties; and zero-place predicates are propositions) is to be found for the first time in Kripke (1963). This, in turn, means that at least Montague saw the seeds of possible worlds semantics for natural languages in Kripke (1963).

This initially seems at least a little bit strange, since nowhere in Kripke (1963) does one find the identification of propositions with functions from possible worlds to truth values or relations with functions from possible worlds to sets of n -tuples. However, it is easy to see why a logician like Montague would see those ideas in Kripke (1963). Consider again a model on a quantificational model structure, forgetting for the moment about functions f that are assignments to free variables and that the domains of members of K can vary, (essentially, this means we are considering a model on a *propositional* model structure). A *model* φ on a $(M/S_4/S_5)$ model structure $\langle G, K, R \rangle$ assigns to a propositional variable (a zero-place predicate—an atomic formula without any variables) and a member of K either T or F. Now consider a particular propositional variable P . Consider the function f_p defined as follows:

For any H in K , $f_p(H) = T$ iff $\varphi(P, H) = T$; otherwise
 $f_p(H) = F$

f_p is a function from worlds to truth values and so can be thought of *a la* Montague as the proposition expressed by P (in the model φ on the model structure $\langle G, K, R \rangle$)! That is, propositions, understood as functions from worlds to truth values, are trivially definable using Kripke's models. Similar remarks apply to n -place relations, understood as functions from possible worlds to sets of n -tuples of individuals. It seems likely that this is why a logician like Montague would take Kripke to have introduced them. Montague, after making the attribution to Kripke, does add (p.154): "... Kripke employs, however, a different terminology and has in mind somewhat different objectives."

These functions from worlds to truth values or sets of n -tuples are now generally called *intensions*. Their values at a world (truth values; sets of n -tuples) are generally called *extensions* (at worlds). The idea that the primary job of semantics is to assign to expressions of natural lan-

guages intensions and extensions of the appropriate sort very much took hold in the wake of work by Kripke and others in the semantics of modal logic.

With the resources Kripke and others had made available in hand, researchers thinking about the semantics of natural languages eagerly made use of them. Thus the late 1960s and early 1970s saw dizzying progress in natural language semantics as the techniques for modal logic were applied. Two works from that era that particularly capture the spirit of the times are Lewis (1970) and Montague (1973). The latter will be discussed here, since it is probably the most sophisticated and influential of the works of that period. The particular semantic phenomena Montague was concerned to understand were the workings of verbs of propositional attitudes like 'believes,' the workings of intensional verbs like 'worships' and related phenomena (see p. 248 where Montague lists some of his concerns).

We saw above that both Frege and Carnap were also concerned with understanding the semantics of verbs like 'believes.' We are now in a position to say more about why such expressions attract the attention of semanticists. Consider the expression 'It is not the case' in sentences like

4. It is not the case that snow is white.
- 4a. It is not the case that Mt. Whitney is more than 14,000 feet high.

Whether a sentence fronted by 'It is not the case' is true or false depends only on the extension/truth value of the embedded sentence. Since both the embedded sentences are true, 4 and 4a are both false. Let's put this by saying that 'It is not the case that' creates *extensional contexts*. As we saw above, 'believes' doesn't create extensional contexts. 3 and 3a can differ in truth value even though the embedded sentences are both true. Let's say that 'believes' creates *nonextensional contexts*. The same is true of 'Necessarily.' The following differ in truth value even though the embedded sentences have the same extensions/truth values:

5. Necessarily, everything is identical to itself.
- 5a. Necessarily, Aristotle is a philosopher.

Finally, intensional verbs like 'worship' exhibit similar behavior and we could extend our characterization of creating nonextensional contexts so as to include such verbs. For even though 'Samuel Clemens' and 'Mark Twain' have the same extension (a certain individual), the following two sentences apparently may differ in extension/truth value:

6. Lori worships Samuel Clemens.

6a. Lori worships Mark Twain.

Now semanticists have been puzzled as to how to think of the semantics of expressions that create nonextensional contexts. But the work of Carnap and Kripke suggested the way to understand ‘Necessarily.’ In particular,

Necessarily S is true at a world w just in case the intension of S maps every world (accessible from w) to true.

In other words, whereas ‘It is not the case’ looks at the extension of the sentence it embeds to determine whether the entire sentence containing it is true, ‘Necessarily’ looks at the intension of the sentence it embeds to determine whether the entire sentence containing it is true. And given Kripke’s semantics, intensions were well defined, respectable entities: functions from worlds to extensions. This made it appear to many that a semantics that assigned intensions to expressions could treat all expressions creating nonextensional contexts. Certainly, Montague had a version of this view.

As indicated above, Montague (1973) wanted to provide semantic treatments of verbs of propositional attitude such as ‘believes,’ intensional verbs such as ‘worships,’ and other phenomena. We will concentrate on these phenomena as well as Montague’s treatment of quantification. Montague (1973) provides a syntax for a fragment of English. The fragment includes common nouns (‘woman’; ‘unicorn’), intransitive verbs (including ‘run’ and ‘rise’), transitive verbs, (including both intensional transitives and “normal” transitive verbs like ‘love’), ordinary names and pronouns, adverbs (including ‘rapidly’ and ‘allegedly’), prepositions, verbs of propositional attitude and modal sentence adverbs (“adsentences”—‘necessarily’). The fragment allows the formation of relative clauses (though they employ the somewhat stilted ‘such that,’ so that we get things like ‘man such that he loves Mary’) and so complex noun phrases, as well as prepositional phrases and quantifier phrases (‘Every woman such that she loves John’). Thus, Montague’s syntactic fragment includes sentences like:

7. Every man loves a woman such that she loves him.

8. John seeks a unicorn.

9. John talks about a unicorn.

10. Mary believes that John finds a unicorn.

11. Mary believes that John finds a unicorn and he eats it.

It should be noted that many sentences of Montague’s fragment had non-trivially different syntactic analyses: that is, distinct syntactic analyses that are interpreted differently semantically. So, for example, 8 above has an analysis on which ‘a unicorn’ is the constituent last added to the sentence and an analysis on which ‘John’ is the last constituent added. The latter has an interpretation on which it may be true even if there are no unicorns and so John is seeking no particular one. The former requires John to be seeking a particular unicorn. Thus, it is really syntactic analyses of sentences, and not the sentences themselves, that get semantic interpretations.

The next aspect of Montague’s semantic treatment of his fragment of English is his intensional logic. Montague’s intensional logic is typed. In particular, e and t are the basic types; and whenever a and b are types, $\langle a, b \rangle$ is a type. Finally, for any type a , $\langle s, a \rangle$ is a type. For each type, there will be both constants and variables of that type (and hence quantifiers of that type). The key to understanding the syntactic interactions of the expressions of various types is to know that if α is of type $\langle a, b \rangle$ and β is of type a , then $\alpha(\beta)$ is of type b . Interpretations assign expressions of the logic various denotations (relative to an assignment of values to variables). Expressions of type e get assigned individuals (possible individuals); expressions of type t get assigned truth values. Expressions of type $\langle a, b \rangle$ get assigned as denotations functions from denotations of type a to denotations of type b . Finally, expressions of type $\langle s, a \rangle$ get assigned functions from a world/time pair to a denotation of type a (“an intension of a type a expression”). To take some examples, expressions of type $\langle e, t \rangle$ get assigned functions from individuals to truth values (the denotations can alternatively be thought of as sets of individuals: those that get assigned to true). Expressions of type $\langle s, e \rangle$ are assigned functions from world/time pairs to individuals. Such functions Montague called *individual concepts*. Expressions of type $\langle \langle s, e \rangle, t \rangle$ are assigned functions from individual concepts to truth values (alternatively, sets of individual concepts). Expressions of type $\langle s, t \rangle$ are assigned functions from world/time pairs to truth values. As indicated above, Montague thought of these as propositions.

The way Montague provided a semantic interpretation of his syntactic fragment of English was to provide an algorithm for translating English sentences (really, syntactic analyses of English sentences) into his intensional logic. Then the interpretation of the English sentences was given by the interpretation of its translation in intensional logic. Recall again that sentences like 8 above can be true even if there are no unicorns. Thus, a verb like

‘seeks’ could not have as its denotation (really, its translation into intensional logic could not have as its denotation) a relation between individuals (or a function from individuals to a function from individuals to truth values).

In order to get the proper results, Montague decided to assign to common nouns and intransitive verbs as their denotations sets of individual concepts rather than sets of individuals. Verbs like ‘believes’ have as their denotations functions from propositions to sets of individual concepts. Since individual concepts essentially function as individuals in Montague’s semantics (recall that common nouns like ‘man’ have as denotations sets of individual concepts), this treatment essentially amounts to holding that verbs of propositional attitude denote relations between individuals and propositions. Quantifiers such as ‘Every man’ denote sets of properties of individual concepts (functions from world/time pairs to sets of individual concepts). Roughly, ‘Every man walks’ is true at a world and time $\langle w, t \rangle$ just in case the property of individual concepts that determines the correct set of individual concepts denoted by ‘walks’ at every world and time is in the set of properties of individual concepts denoted by ‘Every man’ at $\langle w, t \rangle$. ‘Necessarily’ denotes at a world/time $\langle w, t \rangle$ a set of propositions: those that are necessary at $\langle w, t \rangle$.

Finally, a transitive verb denotes a function from properties of properties of individual concepts (denotations of expressions of type $\langle s, \langle \langle s, \langle \langle s, e \rangle, t \rangle \rangle, t \rangle \rangle$)—functions from world/time pairs to sets of properties of individual concepts) to sets of individual concepts. Again, recalling that individual concepts essentially stand in for individuals in Montague’s framework, this means that transitive verbs in effect denote relations between individuals and properties of properties of individuals. Note that this means that for δ to be true at a world/time pair $\langle w, t \rangle$ is for John to stand in a relation to the property of being a property possessed by a unicorn. This can be the case even if there are no unicorns.

Montague chose to treat all expressions of a given syntactic category the same way semantically. This means that transitive verbs like ‘loves’ get the odd denotation required by ‘seeks’ to get δ right. But don’t we want ‘John loves Mary’ to be true at world/time pair iff the individual John stands in a relation to the individual Mary? Surely this shouldn’t require instead that John stands in a relation to the property of being a property possessed by Mary. Where’s the love (between individuals)? Montague essentially requires interpretations to make true meaning postulates for “ordinary” verbs like ‘loves,’ and these end

up insuring that ‘John loves Mary’ is true at $\langle w, t \rangle$ iff John and Mary themselves are properly related.

Montague’s semantic account here was very influential. He showed that the resources Kripke and others developed for the semantics of modal logic could be rigorously applied to natural languages, and arguably treat such recalcitrant expressions as ‘believes,’ ‘necessarily,’ and ‘seeks.’ Montague’s basic approach was picked up by many philosophers and linguists and much work in semantics through the 1980s and beyond was conducted in this framework. Indeed, much work is still done in this and closely related frameworks.

At about the same time Montague was doing his pioneering work on formal semantics for natural languages, Donald Davidson was developing a very different approach to semantics. Davidson (1967) begins with the idea that a theory of meaning for a natural language must specify how the meaning of a sentence is determined by the meanings of the words in it, and presumably how they are combined (in other writings, Davidson puts the point by saying that the meaning of sentence must be a function of a finite number of features of the sentence—presumably, one is its syntax). Davidson thought that only a theory of this sort could provide an explanation of the fact that on the basis of mastering a finite vocabulary and a finite number of syntactic rules, we are able to understand a potentially infinite number of sentences. More specifically, Davidson thought a theory of meaning should comprise an axiomatized theory, with a finite number of axioms, that entails as theorems (an infinite number of) statements specifying the meaning of each sentence of the language. Davidson thought that grasping such a theory would allow one to understand all the sentences of the language. Further, as suggested above, such a theory would explain how creatures like us are capable of understanding an infinite number of sentences. It would only require us to grasp the axioms of the theory of meaning, which are finite in number.

It might be thought that the theorems of a theory of meaning of the sort discussed would be all true sentences of the form ‘*s* means that *p*,’ where ‘*s*’ is replaced by a structural description of a sentence of the language and ‘*m*’ is replaced by a term referring to a meaning. Further, it might be thought that a theory would have such theorems in part by assigning meanings to the basic expressions of the language (such assignments being made by axioms). However, Davidson thinks that we have not a clue as to how to construct such a theory, mainly because we have no idea how the alleged meanings of simpler expressions combine to yield the meanings of complex

expression of which they are parts. Thus, Davidson concludes, postulating meanings of expressions gets us nowhere in actually giving a theory of meaning for a language.

Davidson's counterproposal as to what a theory of meaning should be like is radical. A theory of meaning must be a finite number of axioms that entail for every sentence of the language a true sentence of the form 's is true iff p', where 's' is replaced by some sort of description of a sentence whose theory of meaning we are giving, and 'p' is replaced by some sentence. Henceforth, we will call such sentences *T-sentences*. Recalling our discussion of Tarski, the language we are giving a theory of meaning for is the object language and the theory of meaning is given in the metalanguage. Thus, the formulation just given requires the metalanguage to have some sort of (presumably standardized) description of each sentence of the object language (to replace 's'); if we imagine 'p' to be replaced by the very sentence that what replaces 's' describes (as Davidson sometimes supposes) the metalanguage must also contain the sentences of the object language. In short, Davidson held that to give a theory of meaning for a language is to give a Tarski-style truth definition for it.

Tarski thought that a condition of adequacy for a theory of truth for a (in his case, formal) language L was that the theory has as consequences all sentences of the form 's is true (in L) iff p', where 's' is replaced by a structural description of a sentence of the object language and 'p' is replaced by a translation of it. Here Tarski clearly seemed to think that for one sentence to translate another is for them to share a meaning. However in characterizing what is to replace 'p' in his T-sentences, Davidson cannot require 'p' to be replaced by a translation of the sentence the thing replacing 's' describes, assuming anyway that for one sentence to be a translation of another is for them to share the same meaning. For Davidson eschews meanings. After all, a theory of truth was supposed to *be* a theory of meaning; it would hardly do, then, to appeal to meanings in constructing one's theory of truth. Thus Davidson famously merely requires the T-sentences to be true. But this requirement is very weak, for 'iff' is truth functional in Davidson's T-sentences, and so the sentences require for their truth only that the two sides share a truth value. But then there is nothing in principle yet to prevent having a theory of truth for English that yields not:

12. 'Snow is white' is true (in English) iff snow is white.

but instead

13. 'Snow is white' is true (in English) iff grass is green.

After all, 13 is true! Davidson was aware of this consequence of his view, and explicitly discussed it. He claimed that by itself, the fact that a theory of truth yields 13 as a theorem instead of 12 doesn't cut against it. However, the theory has to get all the other T-sentences coming out true, and Davidson thought it was unlikely that it could do that and yield 13 as a theorem.

Of course, the picture sketched so far needs to be complicated to account for contextually sensitive expressions. It won't do to have as theorems of one's truth theory things such as:

14. 'I am hungry' is true (in English) if I am hungry.

Davidson himself thought that the way to deal with this was to relativize truth to e.g. a speaker and a time (to handle tense). Others have suggested that a theory of truth for a language containing such contextually sensitive words must define truth for utterances of sentences. For example, see Weinstein (1974).

Further complications are required as well. Natural language contains devices not contained in the relatively austere formal languages for which Tarski showed how to define truth. Natural languages contain verbs of propositional attitude ('believes'), non-indicative sentences and other features. Davidson attempted to provide accounts of many such devices in other papers. Davidson (1968) for example takes up verbs of propositional attitude.

One sometimes hears model theoretic approaches to semantics contrasted with those that offer an absolute truth theory. The contrast is illustrated by comparing Montague and Davidson, since each is perhaps the paradigmatic case of one of these approaches. As we saw, Montague gives a semantics for English sentences by associating them with formulae of intensional logic. He then gives a semantics for the formulae of intensional logic. Now the latter includes a definition of truth relative to an interpretation (and other parameters as well). As discussed, expressions of Montague's intensional logic only have denotations (and intensions) relative to interpretations, which are also sometimes called *models*. Roughly, then, a model theoretic semantics is one that defines truth *relative to models or interpretations*. By contrast, as we have seen, Davidson wants a theory of truth simpliciter (actually, truth for L, but truth isn't relativized to models). Thus, Davidson's approach is sometimes called an absolute truth theory approach. I believe it is

fair to say that most semanticists today use a model theoretic approach.

The 1960s and 1970s saw an explosion in the sort of model theoretic semantics pioneered by Montague, Lewis and others. Some of the important developments had to do with evolving notions of an *index of evaluation*. As we saw above, in Montague's intensional logic, expressions are assigned extensions/denotations at world/time pairs (under an interpretation relative to an assignment of values to variables—this will be suppressed in the present discussion for ease of exposition). In particular, formulae are assigned truth values at a pair of a world and time.

Since expressions of Montague's English fragment receive semantic interpretations by being given the interpretation assigned to the expressions of intensional logic they are translated into, exactly similar remarks apply to English expressions and sentences. We shall call these elements at which expressions are assigned extensions (in this case, world/time pairs) *indices*. (Terminology here varies: Montague called these things *points of reference*; Lewis [1970] called them *indices*, which is probably the most common term for them.) It should be obvious why sentences are assigned truth value at worlds. The reason Montague included times in his indices was that his intensional logic included tense operators in order that he could capture the rudimentary behavior of tense in English. Semantically, such operators work by shifting the time element of the index. Thus, where P is a past tense operator, ϕ a formula, w a world and t a time, $P\phi$ is true at $\langle w, t \rangle$ iff ϕ is true at $\langle w, t' \rangle$ for some t' prior to t. Similarly, modal operators shift the world element of the index: Necessarily ϕ is true at $\langle w, t \rangle$ iff ϕ is true at $\langle w', t \rangle$ for all w' .

So the truth values of formulae of Montague's intensional logic, and so of the English sentences they translate, depend on (or vary with) both a world and a time. Of course, it was noticed that the truth values of some English sentences vary with other features as well, such as who is speaking (if the sentence contains 'I'); who is being addressed (if the sentence contains 'you'); where the sentences is uttered (if the sentence contains 'here') and so on. A natural thought was to build into indices features for all such expressions, so that indices would contain all the features that go into determining extensions of expression. Thus, indices would be n-tuples of a world, time, place, speaker, addressee and so on. Lewis (1970) is a good example of an "index semantics" with indices containing many features. However, a number of developments resulted in such approaches being abandoned or at least significantly modified.

Hans Kamp (1971) discovered that in a language with standard feature-of-index shifting tense operators and contextually sensitive expressions that are sensitive to that same feature, such as 'now,' one needs two temporal coordinates. The point can be illustrated using a sentence in which 'now' occurs embedded under e.g. a past tense operator (assume 'one week ago' is a past tense operator):

15. One week ago Sarah knew she would be in Dubrovnik now.

When this sentence is evaluated at an index, there must be a time in the index for 'one week ago' to shift. The embedded sentence ('Sarah knew she would be in Dubrovnik now') is then evaluated relative to an index whose time feature has been shifted back one week. But then if 'now' takes that time as its value, we predict that 15 means that one week ago Sarah knew she would be in Dubrovnik *then*. But the sentence doesn't mean that. So the index must contain a second time, in addition to the one shifted by 'one week ago,' that remains unshifted so that the embedded occurrence of 'now' can take it as its value.

Kamp's requirement of there being two time coordinates is sometimes called the requirement of *double indexing*. I emphasize again that the requirement stems from there being in the language an operator that shifts a certain feature (time, in our case) and a contextually sensitive expression that picks up as its value the same feature. The argument above given for double indexing of times, then, assumes that temporal expressions ('One week ago') are index shifting operators. Many, including the present author, doubt this claim. (See King [2003] for discussion.) But similar arguments (involving 'actual' and 'Necessarily') could be given for double indexing of worlds.

At any rate, on the basis of such considerations, it was thought that minimally, one needed two indices, each of which contained (at least) a world and a time. However it was Kaplan (1989) (written in the early 1970s and circulated for years in mimeograph form) that provided the proper theoretical understanding of double indexing. Kaplan forcefully argued that not only do we need two indices for the reasons Kamp suggested as well as others (see section VII of 'Demonstratives'), but we need to recognize that the indices are representing two very different things, with the result that we need to recognize two different kinds of semantic values. One index represents *context of utterance*. This is the index that provides values for contextually sensitive expressions such as 'I,' 'now,' 'here' and so on. The intuitive picture is that a sentence taken relative to a context of utterance has values assigned

to such contextually sensitive expressions. This results in the sentence having a *content*, *what is said by the sentence*, taken in that context.

So If I utter 'I am hungry now' on June 12, 2006, the content of the sentence in that context, what I said in uttering it then, is that Jeff King is hungry on June 12, 2006. Now that very content can be evaluated at different *circumstances of evaluation*, which are what the other index represents. For simplicity, think of circumstances of evaluation as simply possible worlds. Then we can take the sentence 'I am hungry now' and consider its content relative to the context of utterance described above. That content, or proposition, can then be evaluated for truth or falsity at different circumstances of evaluation (possible worlds). It is true at worlds in which Jeff is hungry on June 12, 2006 and false at those where he is not.

This distinction between context and circumstance, which the two indices represent, gives rise to a distinction between two kinds of semantic value (here we confine ourselves to the semantic values associated with sentences). On the one hand, the sentence 'I am hungry now' has a meaning that is common to utterances of it regardless of speaker or time. It is this meaning that determines what the content of that sentence is taken relative to contexts with different speakers and times. So this meaning, which Kaplan called *character*, determines a function from contexts to propositional content or what is said. By contrast, there is a sense in which the sentence 'I am hungry now' uttered by me now and Rebecca tomorrow means different things. This is because the sentence has different *contents* relative to those two contexts. So content is the other kind of semantic value had by sentences. Contents are true or false at worlds, so contents determine functions from worlds to truth values. In summary, character determines a function from context to content; content determines a function from worlds to truth values. Kaplan's distinction between context and circumstance and the corresponding distinction between character and content has been hugely influential and widely accepted.

Another important feature of Kaplan's (1989) work is his argument that both *demonstratives* (contextually sensitive words whose use requires the speaker to do something like demonstrate (point at) who she is talking about: 'he,' 'she,' 'this,' 'that') and *pure indexicals* (contextually sensitive words that don't require such demonstrations: 'I,' 'today,' etc.) are *devices of direct reference*. If we think of contents of sentences, propositions, as structured entities having as constituents the individuals, properties and relations that are the contents (relative to a context)

of the expressions in the sentence, a view Kaplan likes, we can understand the claim that indexicals and demonstratives directly refer as the claim that these expressions contribute to propositions (relative to a context) the individuals they refer to (in the context). Thus, when I say: 'I am hungry,' the indexical 'I' contributes me to the proposition expressed by that sentence in that context.

Historically, the importance of this direct reference account of indexicals and demonstratives is its anti-Fregean thrust. Recall that for Frege, expressions generally, even those that refer to individuals, contribute to propositions senses that pick out their references and not the references themselves. In claiming that indexicals and demonstratives contribute individuals to propositions rather than senses that pick out those individuals, Kaplan was proposing a radically anti-Fregean account of indexicals and demonstratives. Kaplan's arguments here complemented the anti-Fregean arguments of one of the most influential works in philosophy of language of the twentieth century: Saul Kripke's (1980) *Naming and Necessity*.

Among other things, Kripke (1980) provided powerful arguments against what he sometimes calls *the description theory* of names. On the description theory, names are held to be both synonymous with definite descriptions and (more weakly) to have their references fixed by definite descriptions. So, for example, 'Aristotle' might be thought to be synonymous with 'the teacher of Alexander,' and whoever satisfies this description is the referent of 'Aristotle.' Frege's view was thought to be a version of the description theory, since Frege seems to say that the sense of a proper name can be expressed by a definite description (Frege [1892a] note B), in which case the name and descriptions would be synonymous. Kripke argued very compellingly that descriptions were neither synonymous with, nor determined the reference of, proper names. As to synonymy, Kripke pointed out that whereas

16. The teacher of Alexander taught Alexander.

expressed (nearly) a necessary truth,

17. Aristotle taught Alexander.

expresses a highly contingent truth. But if the name and description were synonymous, the two sentences should be synonymous and so both should be contingent or both should be necessary. But they aren't. Indeed, the name and description seem to function very differently semantically. As Kripke famously noted, whether 17 is true at any possible world depends on the properties of Aristotle at that world. This because 'Aristotle' is what Kripke called a *rigid designator*: the expression designates Aristotle at

every world where he exists, and never designates any individual other than Aristotle. Hence evaluating the sentence at a world always requires us to check Aristotle's properties there. By contrast, 'the teacher of Alexander' presumably designates different individuals at different worlds, depending on who taught Alexander there. Thus, this expression is *non-rigid*.

As to descriptions determining the referents of names, Kripke adduced a number of considerations but perhaps the most persuasive was the following. Consider a name and any description that allegedly fixes the referent of the name, say 'the man who proved the completeness of arithmetic' fixes the referent of 'Godel.' If we imagine that in fact some man Schmidt satisfies the description, we do not conclude that he is the referent of 'Godel.' Quite the contrary, we conclude that the referent of 'Godel,' that is, Godel, fails to satisfy the description. But then the description does not fix the referent of the name (i.e. the referent is not whoever satisfies the description).

The arguments of Kaplan (1989) and Kripke (1980), together with arguments given by Donnellan, Marcus, Putnam and others turned semantics in a very anti-Fregean direction from the 1970s on. This anti-Fregean strain as applied to singular terms is sometimes called *the new theory of reference*.

As we saw above, Kaplan claimed that indexicals and demonstratives were directly referential and contributed their referents (relative to a context) to the propositions expressed by sentences in which they occur (interestingly, this is not reflected in Kaplan's [1989] formal system, which makes use of unstructured propositions that have no constituents corresponding to the words in the sentences that express the propositions; but his informal remarks make clear his intent). By contrast, though Kripke (1980) argued against the descriptive theory of names, he cautiously made no positive claims about what names contribute to propositions (the preface to Kripke [1980] makes clear that this caution was intended—see pp. 20–21). In a series of works in the 1980s, most famously Salmon (1986) and Soames (1987), Scott Soames and Nathan Salmon offered powerful arguments in favor of the view that names too were devices of direct reference and contributed only their bearers to propositions expressed by sentences in which they occur. Both Soames and Salmon defended the view that sentences (relative to contexts) express structured propositions, with names (and indexicals and demonstratives) contributing the individuals to which they refer to proposi-

tions. Salmon and Soames both also thought that attitude ascriptions such as the following:

18. Nathan believes that Mark Twain is an author.

assert that the subject (Nathan) stands in a certain relation (expressed by 'believes') to a structured proposition (expressed by the embedded sentence). If that is right and if names contribute only individuals to propositions expressed by sentences in which they occur, then (assuming a simple principle of compositionality) 18 expresses the same proposition as

19. Nathan believes that Sam Clemens is an author.

Thus, on the Soames-Salmon view 18 and 19 cannot differ in truth value. Though this seems counterintuitive, Soames (1987) and Salmon (1951) offer spirited defenses of this result. Soames (1987) also offers extremely compelling arguments against the view that propositions are unstructured sets of worlds (or circumstances). Some version of the Soames/Salmon view is widely considered to be the standard direct reference view in semantics. Views such as theirs, which make use of structured propositions and endorse direct reference for names, demonstratives and indexicals, are often called *Russellian*.

About the same time the new theory of reference was becoming prominent, quite different developments were taking place in semantics. In pioneering work first presented in the late 1960s (as the William James Lectures at Harvard; later published in Grice [1989] as Essay 2), Paul Grice sought to give a (somewhat) systematic account of (as we would now put it) how the production of a sentence with a certain semantic content can convey further information beyond its semantic content. To give an example from Grice, suppose A and B are planning their itinerary for a trip to France and both know A wants to visit C if doing so wouldn't take them too far out of their way. They have the following exchange:

A: Where does C live?

B: Somewhere in the south of France.

Since both are aware that B offered less information than is required for the purposes at hand, and since B can be presumed to be attempting to cooperate with A, B conveys that she doesn't know where C lives, though this is no part of the semantic content of the sentence she uttered. Grice gave an account of how such information (not part of the semantic content of any sentence asserted) can be conveyed. The account depended on the claim that conversational participants are all obeying certain principles in engaging in conversation. The main idea, as illustrated above, is that conversational partici-

pants are trying in some way to be cooperative, and so to contribute to the conversation at a given point what is required given the purpose and direction of the conversation. Grice's central theoretical idea was that certain types of information exchange and certain types of regularities in conversations don't have purely semantic explanations. The study of how information gets conveyed that goes beyond the semantic content of the sentences uttered falls in the field of *pragmatics*, (which is why, though Grice's work is extremely important, it hasn't been discussed more in an entry on semantics).

In a series of papers that (for our purposes anyway) culminated in Stalnaker (1978), Robert Stalnaker, consciously following Grice, was concerned with ways in which in conversations information can be conveyed that goes beyond the semantic contents of sentences uttered as a result of conversational participants obeying certain principles governing conversation. More specifically, Stalnaker developed an account of how context of utterance and semantic contents of sentences (relative to those contexts) produced in those contexts can mutually influence each other.

Of course, how context influences the semantic content of sentences relative to those contexts was already fairly well understood. As discussed above, for example, context supplies the semantic values relative to those contexts for contextually sensitive expressions such as 'I.' Stalnaker sought to understand how the content relative to a context of a sentence uttered can affect the context. Stalnaker began by introducing the notion of *speaker presupposition*. Stalnaker understood the proposition expressed by a sentence (relative to a context) to be a set of possible worlds (the set of worlds in which the sentence taken in that context is true). Very roughly, the propositions a speaker presupposes in a conversation are those whose truth he takes for granted and whose truth he thinks the other participants take for granted too.

Consider now the set of possible worlds that are compatible with the speaker's presuppositions (the set of worlds in which every presupposed proposition is true). Stalnaker calls this *the context set*, and it is for him a central feature of a context in which a conversation occurs. (Strictly, every participant in the conversation has his own context set, but we will assume that these are all the same—Stalnaker calls this a *non-defective context*.) They contents of sentences (relative to a context) affect the context in the following way: if a sentence is asserted and accepted, then any world in the context set in which the sentence (taken in that context) is false is eliminated from the context set. In short, (accepted) assertions function to

reduce the size of the context set, or eliminate live options.

Stalnaker uses this idea to explain a variety of phenomena, including how the utterance of sentences with trivial semantic content (relative to a context) can nonetheless be informative. It is important to see that Stalnaker, like Grice, took his account here to be not part of semantics, but rather to be something that presupposed the semantics of sentences (taken in contexts). In short, like Grice's work, it was work in pragmatics. However, Stalnaker's idea that the information conveyed by the utterance of multiple sentences in a discourse can go beyond anything countenanced by traditional semantics and that it is important to understand the dynamics of conversation to understand how information is conveyed influenced others who went on to develop *semantic* theories that capture the dynamics of conversation, (Lewis [1979] was another important early influence to the same effect).

In the early 1980s, Irene Heim (1982) and Hans Kamp (1981) independently arrived at very similar semantic accounts that were intended to apply to multi-sentence discourses. Kamp's view is called *Discourse Representation Theory (DRT)* and Heim's view is sometimes called that or *File Change Semantics (FCS)*. To take a simple example of the sort that DRT and FCS were designed to handle, consider a (short) discourse such as:

20. Alan owns a donkey. He beats it.

Using Kamp's formulation, the *discourse representation structure (DRS)* associated with the first sentence of 20 would (roughly) look as follows:

$x_1 x_2$
 $x_1 = \text{Alan}$
 $\text{donkey}(x_2)$
 $x_1 \text{ owns } x_2$

After the utterance of the second sentence, the DRS associated with the entire discourse would look as follows, where we have simply added one more line (*a condition*) to the DRS for the first sentence of 20 (we assume that 'He' is anaphoric on 'Alan' and 'it' on 'a donkey'):

$x_1 x_2$
 $x_1 = \text{Alan}$
 $\text{donkey}(x_2)$
 $x_1 \text{ owns } x_2$
 $x_1 \text{ beats } x_2$

Note that expressions like ‘a donkey’ introduce variables (called *discourse referents*) and predicates (‘donkey’) into DRS’s and not existential quantifiers. Again very roughly, this DRS (and hence the original discourse) is true in a model iff there is an assignment to the variables of the DRS that results in all its conditions being true in that model. It is the requirement that *there is* such an assignment that results in default existential quantification of free variables. So though indefinites like ‘a donkey’ are not existential quantifiers on this view, they have existential force (in this case, anyway) due to default existential quantification of free variables. Aside from the desire to apply semantics at the level of discourse instead of sentence, much of the motivation for DRT and FCS came from cases such as 20 (and others) in which a pronoun is anaphoric on another expression (see entry on *anaphora*).

DRT and FCS led directly to the development of other semantic accounts designed to capture the dynamics of conversation. In the paper that initiated what is now often called *dynamic semantics*, Groenendijk and Stokhof (1991) make clear that they see their account as a descendant of DRT and throughout the paper they compare their *Dynamic Logic (DL)* account to DRT. The basic idea of DL is that instead of thinking of expressions as having “static” meanings, think of meanings as things that given inputs, produce outputs. A bit more formally, think of the meanings (in models) of formulae of first order logic as given by the sets of assignments to variables that satisfy the formulae. So for example, the meaning of ‘Fx’ in a model M is the set of all assignments such that they assign to ‘x’ something in the extension of ‘F’ in the model M. Dynamic logic claims that the meaning of a formula in first order logic is a set of *pairs* of assignments: the first, the input assignment; the second, the output assignment. For “externally dynamic” expressions (e.g. conjunction, existential quantifiers), these can differ and the result is that interpreting these expression can affect how subsequent expressions get interpreted. For since the output assignments can be different from the input assignments for these dynamic expressions, and since the output of these expressions may be the input to subsequent expressions, the interpretation of those subsequent expressions may be affected.

There is currently much research being done within the framework of dynamic semantics, particularly among linguists. Muskens, van Benthem and Visser (1997) provide a good general overview.

There are many important topics in semantics that could not be covered in the present article. These include

the theory of generalized quantifiers, the semantics of conditionals, the semantics of non-declarative sentences, the semantics of metaphor and two dimensional semantics. Interested readers are encouraged to pursue these matters on their own.

SEMANTICS, HISTORY OF

The scope of this article is in part determined by the following restrictions. (1) Although the development of semantics in the twentieth century equals or surpasses all that was done earlier, it receives very little attention here because the major theories and theorists of this period are thoroughly discussed in other articles. (2) The only semantic theories considered are those developed by Western philosophers; thus, no account is taken of the theories of meaning propounded, for example, by ancient Hindu philosophers or by European grammarians or linguists. (3) Since semantic theories concerning nonlinguistic signs tend to involve considerations of theories of knowledge generally, they are not discussed here except as they may occasionally bear directly on a theory of linguistic meaning. On the other hand, much of what philosophers have had to say about language is discussed here, whether or not it can be precisely described as semantics.

ANTIQUITY

THE COSMOLOGISTS

Since the earliest Greek philosophers were primarily cosmologists, their views on language are not the most fully developed (or best preserved) of their doctrines. Sources very late in antiquity attributed to Pythagoras (fl. 530 BCE) the view that although the soul assigned names to things, it did so not arbitrarily but on the basis of a natural connection between them, somehow like that between mental images and their originals. Modern historians sometimes credit Heraclitus (fl. 500 BCE) with having thought a great deal about language, but most of the fragments offered in evidence have to do with the *logos*, which surely is to be interpreted as the guiding principle of nature rather than as word or language. While we have nothing of his explicitly on language, it seems likely that Heraclitus did attach philosophical significance to the puns or contradictions in terms on which some of his paradoxical remarks depend.

Semantic theory seems to have made its first definite appearance in philosophy in the monism of Parmenides (fl. 475 BCE), who maintained that only what was true was expressible. He evidently based this remarkable doctrine on the argument that a statement is false if and only if it contains a false name, but a false name is by definition a name lacking a real bearer and hence a name that names or expresses nothing. (His monism of course entailed that there was only one real name-bearer.) Thus he described several words, such as “becoming” and “perishing,” as “mere names that mortals have established, believing them to be true”—that is, believing that there really are such processes, which Parmenides denied.

THE SOPHISTS

Language first became a subject of specialized inquiry among the Sophists, who, unlike their philosophical predecessors, were more interested in man than in the cosmos. That orientation alone would probably have drawn them to the study of language, but there was also

the fact that they earned their livings teaching people to speak well. Economic as well as philosophical considerations therefore probably played a part in leading them to include at least grammar as an important part of their work. Protagoras (fl. 445 BCE), the first of the Sophists, may also be considered the first grammarian. He distinguished the tenses and something like grammatical moods (classifying sentences as answers, questions, commands, and wishes), and he classified nouns as masculine, feminine, and “inanimate” (a division based on semantical rather than syntactic considerations, since it depended on the particular sex or lack of sex in the things the nouns were used to name). Grammar developed rapidly among the Sophists. Among the more philosophically interesting parts of grammatical theory to be found in Plato, who doubtless learned much of it from the Sophists, are distinctions between subject and predicate, between substantive and adjective, between the active and passive voices, and among types of discourse—political, rhetorical, conversational, dialectical, and technical.

The Sophists originated semantical as well as grammatical inquiries. Prodicus (fl. 435 BCE), who Plato thought was the best of the Sophists on language, seems to have operated on the hypothesis that there were no genuine synonyms, that where there were two words, there were two meanings. In Plato’s dialogues Prodicus is depicted drawing instructive distinctions between “enjoyment” and “pleasure,” “esteem” and “praise,” “fearlessness” and “courage,” for example; and he insisted on the study of “the right use of words” as the beginning of education. Protagoras, Prodicus, and Hippias (fl. 435 BCE) are all credited with treatises on “the correctness of names,” and Socrates (d. 399 BCE) is depicted discoursing on that subject in Xenophon’s *Memorabilia* (III, xiv, 2–7).

Semantics may have become a theoretical issue for the first time in the paradoxical arguments propounded by Gorgias (fl. 435 BCE) in support of his third nihilistic thesis. The three theses were (1) nothing exists; (2) even if something existed, it would be unknowable; (3) even if something existed and were knowable, it would be incommunicable. Gorgias gave four arguments for thesis (3) along the following lines. Suppose there really are things and they can be perceived by our senses. Then (a) some of those things will be perceivable by one sense only and others by another sense only; and since one sense cannot perceive objects proper to another sense, a system of audible signs will not permit communication regarding things perceivable only by sight, and so on for the other senses. In any case, (b) those supposed things are not identical with any signs one might use to communi-

cate about them, and so one could never convey the things themselves to another person but only the signs.

Moreover, (c) even if one could produce signs exactly representing those supposed things, he could not communicate those signs to another person, for the signs themselves are things, and no one can have in his mind the same things that someone else has in *his* mind at the same time. Finally, (d) any signs we might use would have to be formed as a result of our perception of those supposed things, but since genuine knowledge of a cause cannot be gained from its effect, no knowledge of those things could be communicated by means of any signs. Occasionally in arguments (a), (b), and (c) Gorgias seems, like Jonathan Swift's *Laputans*, to have sophistically confused talking about things with handing them around; but not all his paradoxes of communication are transparent, and some passages in Plato and Aristotle suggest that Gorgias's arguments may have helped to shape their semantic theories.

CONVENTIONALISM AND NATURALISM

The oldest surviving arguments in support of a particular semantic theory may be those attributed very late in antiquity to Democritus (fl. 420 BCE), perhaps presented originally in his book *On Words*. He is supposed to have offered the following four considerations in support of his position that the relation between names and things named is conventional (*θέσει*) rather than natural (*φύσει*): (a) the occurrence of homonyms, that is, one and the same name for things different in nature; (b) the occurrence of synonyms, that is, different names for one and the same thing; (c) the occurrence of name-changes while the thing named remains the same in nature; (d) the nonoccurrence of verbal analogies corresponding with real analogies, for instance, there is a verb analogous to the noun "understanding" but none analogous to "justice."

In all probability no philosopher ever held a thoroughgoing semantic naturalism, although there are traces of tendencies in that direction in the doctrine attributed to Pythagoras and in the assumptions that appear to underlie the work of Prodicus and Gorgias. The opposition of naturalism and conventionalism as semantic theories forms the point of departure for the development of Plato's semantics of names in the *Cratylus*. Much of the significance of the *Cratylus* and of ancient philosophy of language generally has been obscured, from antiquity onward, by the confusion of this semantic issue with a dispute over the origin of language in which "naturalism" and "conventionalism" were the principal doctrines. In

that dispute, however, it was not the naturalist but the conventionalist position that was preposterous, conventionalism in that context being the claim that language first arose as a result of agreements among men or because some especially powerful individual compelled those around him to use his names for things. There are, of course, implications for semantics in theories about the origin of language, but neither Plato nor any other ancient philosopher of the first rank failed to distinguish between the two inquiries.

PLATO

The oldest surviving work of any kind on language is Plato's *Cratylus* (probably written about 388 BCE). The main topic of this dialogue is the nature of the relation between names and things named.

THE CRATYLUS. At the beginning of the *Cratylus* a kind of semantic naturalism is attributed to Cratylus and a kind of semantic conventionalism to Hermogenes. All that is said about naturalism at the outset is that it seems unintelligible, and the first serious undertaking is a discussion of the conventionalism advanced by Hermogenes in these words:

I cannot be persuaded that there is any correctness of name other than convention [*ξυνθήκη*] and agreement [*δμολογία*]. For it seems to me that whatever name anyone gives to a thing is the correct one, and if someone changes that name for another, the later one is no less correct than the earlier—just as when we change the names of our slaves. For no name has been generated by nature for any particular thing, but rather by the custom [*νόμος*] and usage [*ἔθει*] of those who use the name and call things by it. (384 C–D)

There is nothing in this conventionalism we have not already seen in the Democritean arguments except the claim that "whatever name anyone gives to a thing is the correct one," and Socrates immediately asks whether this claim is intended to apply to private persons as well as to nations (385A). Hermogenes fails to appreciate the difference, and when, as a result, Socrates is on the point of showing that this subjectivist claim destroys the possibility of distinguishing between true and false statements, Hermogenes tries to salvage it by suggesting an analogy between arbitrary individual name-giving and different natural languages (385D–E). The picture presented is that of a conventionalist who recognized that the existence of different autonomous natural languages was strong con-

firmation of his position and was then so carried away as to produce a doctrine of autonomous idiolects, evidently reasoning as follows: Just as the Greek word for horse is no more and no less correct than the Persian word for horse, so there is no basis for correcting a Greek who should decide to use the Greek word *anthropos* where other Greeks use *hippos* and vice versa.

The conventionalism presented as a basis for discussion in the *Cratylus* is entirely plausible except for the obviously untenable doctrine of autonomous idiolects. One consequence of the doctrine is that at any given time a given thing (or type of thing) has just as many correct names as there are people who name it differently (385D). This suggests some sort of Protagorean skepticism in its author, but Hermogenes is ready to agree that “things have some fixed reality of their own, not relative to us or caused by us” (386D). Socrates uses this admission to show the necessity of objectively correct names. There are real things, he says, and real things are not subject to our whims. We recognize that we cannot do certain jobs involving real things simply by fiat. We must make the correct moves, using the correct tools, and the correct tools for a given job cannot be generally described as the first ones anyone may choose (386E–387B). Now in the use of language, names are our tools, and we employ those tools in doing two essential jobs plainly involving real things: “teaching” (communicating the truth) and “classifying things according to their natures” (387B–388B). If “whatever name anyone gives to a thing is the correct one,” we clearly have no chance of succeeding in communicating the truth to one another or in developing classification schemes that will “carve reality at the joints.”

The destruction of the doctrine of autonomous idiolects leaves a gap in conventionalism, a gap that was there in any case but that would not have been so easily seen if Plato had not thus deliberately marred this conventionalism in order to call attention to it. Not just anyone is an arbiter of the correctness of names; but then “who *does* provide us with the names we use?” (388D). The answer is derived from the sounder portions of Hermogenes’s conventionalism, in which he claimed that custom or law generates our names for things. This suggests that the arbiter of custom, or the lawgiver (*νομοθέτης*), may be identified as the name-maker (*ὀνοματουργός*) (388D–389A). The “law-giver” is Plato’s personification of a recognized stipulative linguistic authority, more nearly like the French Academy or the *Oxford English Dictionary* than like an individual—Solon, for instance.

This refurbished conventionalism is adequate as far as questions of pronunciation, word order, and usage are concerned; these can be settled by having recourse to the recognized authority. The question raised by the criticism of autonomous idiolects, however, was not, “how do we determine which names are *accepted*?” but, rather, “how do we determine which names are *correct*?” Plato took the two questions to be distinct and made his most important contribution to the semantics of names in answering the second of them. The development of his answer may be traced out as follows.

If the refurbished conventionalism is to do any more than offer an account of the phenomena of a language, it must be augmented by part of Cratylus’s naturalism, which was originally stated in these three claims: “(a) for each of the things that really exist there is a correctness of name that has been produced by nature; (b) that is not a name which some people agreeing together to give as a name do give as a name, uttering a bit of their voice in accordance therewith; but (c) there is a kind of correctness of names that is the same for all, both Greeks and barbarians” (383A–B).

At the beginning of the dialogue this position was taken to be unintelligible because it was thought to be in competition with conventionalism as an account of the phenomena of a language. Claim (b) does seem to justify the view that the theory is just a wrongheaded account of that kind. Temporarily ignoring claim (b), Socrates proceeds to show that this naturalism makes sense as an account of the conceptual underpinnings of all languages. The fact that the word for horse in Greek is “hippos” and in Latin “equus” shows that different linguistic authorities are operative in different natural languages. Both those words are perfectly acceptable, intertranslatable names for horse; and what makes them so is the fact that each of them embodies in different marks (or sounds) a single “ideal name,” which belongs to horse “by nature,” whose correctness has been produced by nature, and which is the same for all, both Greeks, who say “hippos,” and “barbarians,” who say “equus” (389C–390A). That single ideal name cannot be the type of which occurrences of “hippos” or of “equus” are the tokens, since it is “the same for all.” Nor can it be identified with what Plato called the form of horse, for although the form of horse may be the ideal *horse*, there is nothing of which it could conceivably be a *name*. Instead, the ideal name embodied as well in “equus” as in “hippos” is the correctly framed concept *horse*, and the difference between the two words is merely the difference between two equally good notations. To say that the concept is

framed correctly is to say that it is the concept of the form rather than of individuals participating in that form; to say that its correctness has been produced by nature is to say that it somehow resembles the form. The correctly framed concept *horse* is a logically proper name of the form of horse; it is the ideal name for which all the words correctly translatable into English as “horse” are various notations.

Plato goes on to develop and apply this theory along the following lines. If we should come across a natural language the speakers of which owned horses and cows but had only one name for both species, or had no single name for horse, using instead an indifferently ordered string of names for legs, head, tail, and so on, then we should have a genuine case of incorrect names. The speakers of that language would be laboring under the influence of incorrectly framed concepts, concepts that fail to carve reality at the joints. Thus, we avoid incorrect names (such as “phlogiston”) to the extent to which philosophy and science (personified by Plato as “the dialectician”) have provided us with a correct conceptual schema (390C–E).

But the embodiment even of correctly framed concepts in the evolving phenomena of a natural language will sooner or later lead to the development of homonyms and synonyms, which, although not incorrect, are infelicitous for the purposes of science and philosophy. Such infelicities could be avoided if we were to construct a precise, consciously designed concept-notation for the use of philosophers and scientists (421E–423E, 424D–425A). And even if we do not or cannot actually construct it, the notion of a perfectly systematic embodiment of correctly framed concepts may serve as an ideal against which to measure the adequacy of technical language (435C). Thus, the frequently recurring project of an ideal language is to be found for the first time in the very first extant treatise on language.

Perhaps the single most unusual feature of this remarkable semantic theory is the doctrine of the ideal name. Within the *Cratylus* itself the identification of the ideal name with the correctly framed concept is not explicit, although it is clearly implied. That implication is strengthened by the many passages in other dialogues in which Plato did treat concepts as a kind of name—for instance, *Theaetetus* 189E, 206D; *Sophist* 263E; *Philebus* 38E–39A; *Phaedrus* 276A.

Cratylus’s naturalism and Hermogenes’s conventionalism are so expressed in the dialogue as to give every appearance of being simply Plato’s devices for raising semantic questions. Each of them contains an obvious,

completely gratuitous overextension. (Later in the dialogue [428A ff.] Cratylus’s claim [b] goes the way of Hermogenes’s autonomous idiolects.) Neither position alone is remotely plausible or likely to have been actually held by any philosopher, but each of them contains an essential ingredient of Plato’s own semantics of names.

THE PARMENIDES AND THE SOPHIST. Plato’s other major contributions to semantics occur in the later dialogues *Parmenides* and *Sophist*, in which he goes beyond the doctrine of the *Cratylus* in undertaking the connected tasks of (1) giving an account of the semantics of such names as lack existent bearers, (2) refuting the Parmenidean doctrine that false statements express nothing, and (3) giving an account of the semantics of simple statements.

(1) In *Parmenides* 160B–161A there is an attempt to state three necessary conditions for the meaningfulness of a denial of existence. (The example actually employed is the hypothesis “if a One does not exist,” which is eminently generalizable.) If we are meaningfully to say of x that it does not exist, then (a) “there is knowledge of” x (since “otherwise the very meaning of ... ‘ x ’ does not exist” would be unknown”); (b) x is “something different from other things”; (c) “this non-existent [x] has the characters of being *that*, and *something*, and of *being related to this*, or *to these*, and all other such characters.... If it does not exist, there is nothing against its having many characters; indeed it must [have many characters] if it is *this* [x], and not another, that does not exist. If what is [said] not to exist is neither *the* [x], nor *this*, and the statement is about *something else*, we ought not so much as to open our lips.” These three interdependent conditions do not seem inconsistent with the semantics in the *Cratylus*, and much of what was to be brought out later in the *Sophist* is already implicit in them—for instance, the distinction between existential and predicational occurrences of “is” (“if it does not exist, there is nothing against its having many characters”).

(2) When Parmenides or Plato speaks of expressing nothing, he means saying nothing meaningful, rather than saying nothing at all. This is implied in Parmenides’ fragments and is quite plain in Plato, when he says, for example, “Must we not assert that [a man] is not even expressing anything when he sets about uttering the words ‘a thing that is not?’” (*Sophist* 237E; *Cratylus* 429E). Those words constitute what Parmenides called a false name. A true, or meaningful, name is one having an identifiable existent bearer, a name that signifies something real; and there is no sharp semantical distinction between

true names and true statements—“If we are speaking the truth, evidently the things we are speaking of must be” (*Parmenides* 161E).

Thus the Parmenidean doctrine is that false statements are meaningless, or that truth and meaningfulness are indistinguishable. Although its scope was never restricted, the doctrine makes most sense when applied to statements of the form “*x* exists,” with which Parmenides was preoccupied. Such a statement, he would say, either is true or expresses nothing. In order to preserve the possibility of falsity, even in the limiting case of such statements, Plato had to question the Parmenidean dictum and establish that *what is not* has being in some respect (*Sophist* 241D), which he does in the complex, important doctrine of the interweaving of the Forms (252E–259C). However, his most direct answer to the Parmenidean doctrine is developed in his semantics of statements, an account based directly on the ontological theory just mentioned, since “any discourse we can have owes its existence to the weaving together of Forms” (260A).

(3) “Now, remembering what we said about Forms, ... let us consider words in the same way.... Words that when spoken in succession signify something, do fit together, while those that mean nothing when they are strung together do not” (261D–E). “Now a statement never consists solely of names spoken in succession, nor yet of verbs apart from names” (262A). Thus “the simplest and shortest possible kind” of statement is exemplified in “Theaetetus sits” or “Theaetetus flies,” “because ... it gives information about facts or events; ... it does not merely *name* something but *gets you somewhere* by weaving together verbs and names. Hence we say it *states* something” (262D). “Whenever there is a statement, it must be *about* something” (262E). Both the examples above are about one and the same existent thing, the bearer of the name “Theaetetus,” but the second is a combination of name and verb in which “what is different is stated as the same or [as is actually the case in this example] what is not as what is,” and anything “answering to that description finally seems to be really and truly a false statement” (263D).

In the *Parmenides* and *Sophist*, then, Plato not only extended semantics for the first time beyond the consideration of names to that of statements but, in doing so, also distinguished between meaningfulness and truth, showing for the first time that truth depends not merely on names but on certain syntactically regular combinations of verbs and names. It should be noted, however, that he does seem to have taken meaningfulness as the necessary and sufficient condition of grammaticalness.

Plato’s semantics of statements may be better appreciated against the background of the semantical doctrines of his contemporaries Antisthenes the Cynic (fl. 390 BCE) and Stilpo the Megarian (fl. 340 BCE). Beginning with the familiar “two names, two bearers” view, Antisthenes managed to reject all predication, on the grounds that what the subject named was one thing and what the predicate named was quite another, and to accept only identity statements of the form “*x* is *x*” or analogies of the form “*x* is like *y*.” Stilpo, too, rejected predication, perhaps on ontological grounds, since he insisted on “the unity of being” and may have thought that this could be expressed only in strict identity statements.

ARISTOTLE

Aristotle’s primary interest in language was naturally that of a logician, and while his writings contain many passages on semantic questions, there is relatively little developed theory. His semantics of words (he treats of more than just names) is like Plato’s in many respects and is to be found mainly in *De Interpretatione*, Chapters 1–3. There he presents, with little or no argument, the following account of signification.

Although there are different natural languages, the people who use them are confronted with the same extramental things. The mental modifications arising from that confrontation are likenesses (*ὁμοιώματα*) of the things, and they are thus the same for all men too. Within a given natural language, written words are conventional symbols (*σύμβολα*) of spoken words. (Aristotle was no doubt unaware of ideographic notations.) The spoken words are, in turn, related to the mental modifications, first of all as symptoms, or natural signs (*σημεῖα*), of them—that is, of the presence of mental modifications in the speaker. More important, the spoken words are related to the mental modifications in the same way that written words are related to spoken words, as symbols of them. Just as written words constitute a conventional notation for (or embodiment of) spoken words, so do spoken words for mental modifications. Discussions of these passages have almost invariably failed to recognize the first of the two relations between spoken words and mental modifications as distinct and have confused the second relation with that of name to bearer.

It seems that, according to this account, words signify things in virtue of serving as symbols of mental modifications resembling those things. What sorts of “things” can words thus be made to signify? Not much is said on that question in *De Interpretatione*, but in *Categories* (Ch. 5) and *Sophistical Refutations* (Ch. 22), for example, vari-

ous words are said to signify (*σημαίνειν*) “a certain *this*,” “a qualification,” “a substance of a certain qualification,” “passivity,” “a certain relation to something else,” “a quantity,” and so on. More important, “‘man’ and every common name signifies not a certain *this*, but a quality or a relation or a mode (or something of the sort)” (*Sophistical Refutations* 178b38).

Ambiguity, Aristotle maintained, is theoretically unavoidable, for since “names and the sum-total of formulas [*λόγοι*] are finite while things are infinite in number ... the same formula and a single name must necessarily signify a number of things.” This will, however, give us no trouble unless “we think that what happens in the case of the names happens also in the case of the things, as people who are counting think of their counters,” which are in a one-to-one correspondence with the things counted (*Sophistical Refutations* 165a5). Although this passage is part of a warning against sophisms of ambiguity, when taken together with the preceding passage it seems to constitute an injunction against seeking the bearer of a common name, as Plato and so many of Aristotle’s successors did. A single individual is the bearer of many names in that they are all correctly predicable of it, but “we do not identify having one meaning with being predicable of one thing, since on that assumption even ‘musical’ and ‘white’ and ‘man’ [all of which are predicable of Socrates] would have one [and the same] meaning” (*Metaphysics* 1006b15).

The principal kinds of words recognized by Aristotle were the name (*ὄνομα*) and the verb (*ῥῆμα*—“predicate” is possibly a more accurate translation). He described them both as the smallest conventionally significant units, incapable of being true or false independently. A name without a bearer, such as “unicorn,” is neither “false” (as some of his predecessors had claimed) nor nonsignificant; and a name combined with “is,” “was,” or “will be” always produces something true or false. A verb uttered by itself is a name, but it additionally signifies time and “some combination, which cannot be thought of without the components.” Because of the latter additional signification, a verb “is always a sign (*σημεῖον*) of things being said of something else” (*De Interpretatione* 16b24, 16b7).

“Non-man” names nothing definite and so is not strictly a name; analogously, “does not walk” holds indifferently of all sorts of existents and nonexistents. These negated words Aristotle put into the separate categories of “indefinite names” and “indefinite verbs.” “Inflections,” such as “man’s,” are not names either, since they produce nothing true or false when combined with “is,” “was,” or

“will be”—nor is “walked” a verb; it is an “inflection,” because it signifies additionally “a time outside the present.” In “complex names,” such as “lifeboat,” the parts are significant, but not independently, since, for example, “life” in this occurrence cannot be given an ordinary interpretation (*De Interpretatione*, Chs. 2 and 3). Finally, there are “connections” (*σύνδεσμοί*), words and phrases that “make many things one” (*Rhetoric* III, 12; 4), which seem to include particles, conjunctions, prepositions, and idiomatic phrases of several sorts and which in one passage of doubtful authorship are said to be nonsignificant (*ἄσημοι*) (*Poetics*, Ch. 20). (The “connections” are almost certainly the direct ancestors of Priscian’s “syncategoremata,” which figured prominently in medieval semantics.) This loosely organized classification, vaguely consistent at best, is based on a tangle of semantic and syntactic considerations, but it does contain important advances—for instance, in the treatment of names without bearers and complex names.

Aristotle’s semantics of sentences is concentrated in but by no means confined to *De Interpretatione*, Chapters 4–8. Names have no significant parts and complex names no independently significant parts, but a sentence (*λόγος*) must have independently significant parts. (This is surprising in view of the fact that in a highly inflected language such as Greek there are frequent occurrences of one-word sentences—“I-walk,” “he-walks,” and so on.) “Every sentence is significant—not as a tool but ... by convention,” he maintained (16b33), apparently dissociating his view from Plato’s in *Cratylus* 386D ff. Plato, however, was talking about names, not sentences, and Aristotle here seems to have gratuitously set aside an insight into the semantics of sentences that was later to be developed by the Stoics. Some sentences, such as “prayers” and future contingents, are neither true nor false according to Aristotle, and he set the pattern for nearly all logicians thereafter when he put such sentences aside and attended solely to the always true or false “statement” (*λόγος ἀποφαντικός*).

Aristotle maintained that among the independently significant parts of a statement there must be either a name or an indefinite name and a verb or an inflection of a verb arranged in such a way that the whole “signifies something about something.” It is only in such a combination that there is truth or falsity, and, as Aristotle put it in the early chapters of *De Interpretatione*, it looks as if he took the combination in question to be one of words. In *Metaphysics* 1027b23, however, he said that “falsity and truth are not in things ... but in *thought*; while with regard to *simple* concepts and essences falsity and truth

do not exist even in thought ... but ... the combination and the separation are in thought and not in things,” and he suggested something similar in *De Interpretatione*, Chapter 14 (and elsewhere), as well (cf. Plato, *Republic* 382B). There is no evidence that Aristotle distinguished consistently or clearly between sentences and what later philosophers called propositions or judgments, but such passages indicate at least his sense of the difficulty in locating truth in strings of words, or in a direct relation between strings of words and arrangements of things.

Aristotle seems sometimes to have considered the communicative capacity or public character of a locution as a criterion of its having independent significance. Thus in *Metaphysics* 1006a21 he remarked that if a man “really is to say anything,” he must “say something that is significant both for himself and another”; and in support of his claim that when a verb is uttered by itself it is really a name and signifies something, he noted that on such an occasion “the speaker arrests his thought and the hearer pauses.”

THE STOICS

The nature of the Stoics’ philosophy of language is the most tantalizing problem in the history of semantics. We know enough of it to say that it was by far the most intricate and probably the most insightful theory of its kind in antiquity and for centuries afterward; but we cannot be certain what its details were, and even its leading principles are sometimes obscured by vague or conflicting testimony. Those Stoics who had most to say about language were, naturally, the logicians, and the difficulty of determining the exact character of what they had to say stems from the fact that none of the many works of the Stoic logicians is extant. The best surviving sources (which date from almost five hundred years after the period of greatest development in Stoic logic and semantics) are Sextus Empiricus, *Outlines of Pyrrhonism*, Book II, and *Adversus Mathematicos*, Book VIII; and Diogenes Laërtius, Book VII. Under these circumstances it is seldom possible to assign a particular doctrine to a particular Stoic, but much of the best of their logic and semantics is very likely to be the work of Chrysippus (c. 280–206 BCE).

Under the Stoic division of philosophy into physics, ethics, and logic, logic was divided into rhetoric and dialectic, and dialectic further divided into an account of language (*περὶ τῆς φωνῆς*) and an account of things signified (*περὶ τῶν σημαινόμενων*). Both these subdivisions contain material relevant to semantics. In their account of language the Stoics distinguished vocal sound generally, “which may include mere noise,” from the sort that is

articulate (*ἔναρθρος*), that is, capable of being embodied in written symbols (*ἐγγράμματος*). Articulate sound, in turn, may be nonsignificant—for instance, “blityri”—or significant (*σημαντικῆ*); but for any articulate sound to be considered a sentence (*λόγος*) it must be significant and a product of someone’s reason (Diogenes Laërtius 7.55–57).

Within that same branch of their dialectic the Stoics recognized five kinds of words and distinguished their semantic or syntactic functions. They were the first who clearly separated (1) names, such as “Socrates,” from (2) appellatives (*προσηγορία*), such as “man.” (Cf. Aristotle’s similar but significantly different distinction in *De Interpretatione*, Ch. 7.) A name “points out a kind proper to an individual,” while an appellative “signifies a common kind.” (3) A verb “signifies a predicate”; (4) a conjunction “binds together the parts of a sentence”; (5) an article (possibly also what would now be called a relative pronoun) serves to “distinguish the gender and number of nouns” (Diogenes Laërtius 7.58). Thus the function of conjunctions and articles is purely syntactic, the semantic function of (proper) names is different from that of appellatives (or common names), and the appellative and the verb—the standard ingredients of the simplest kind of logicians’ sentence—have one and the same kind of semantic function. The appellative occurring in a sentence signifies a subject and the verb a predicate or “something attachable (*συντακτόν*) to the one or more subjects.”

Obviously the division between the accounts of language and of things signified was not exclusive, but the transition from the one account to the other as the Stoics conceived of them may be seen in the claim that all we utter (*προφέρειν*) is sounds, while what we express (*λέγειν*) is matters of discourse (*πράγματα*), or *lekta*—“expressibles” (Diogenes Laërtius 7.57). It is the doctrine of the *lekton* around which the Stoics organized their account of things signified. In its novelty, importance, and difficulty that doctrine overshadows all the considerable remainder of their philosophy of language.

THE LEKTON. Probably the clearest introduction of the notion of the *lekton* is the one to be found in these passages from Sextus:

The Stoics ... said that three things are linked together: (1) what is conveyed by the linguistic sign [*τὸ σημαινόμενον*], (2) the linguistic sign itself [*τὸ σημαίνον*], and (3) the object or event [*τὸ τυγχάνον*]. Of these the linguistic sign is the sound—e.g., “Dion”; what is conveyed by the

sign is the matter of discourse indicated thereby, which we apprehend over against and corresponding to our thought (while the barbarians do not understand, although they do hear the sound); and the object or event is the extramental entity—e.g., Dion himself. Two of these are corporeal—viz. the sound and the object or event—and one is incorporeal—viz. the matter of discourse conveyed by the linguistic sign, the lekton. (*Adversus Mathematicos* 8.11–12)

They also say that the lekton comes into being as corresponding to a rational presentation [*λογικὴν θαντασάν*], and that a rational presentation is one presenting something that can be set forth in a sentence. (*Adversus Mathematicos* 8.70)

The kind of lekton associated with the name “Dion” was said to “stand in need of completion,” and the only categories cited for such completable lekta were subjects and predicates. In order to be “set forth in a sentence,” the completable lekta must enter into the composition of a lekton “complete in itself.” The kind of complete lekton regularly associated with a standard subject-predicate sentence was called a statement (*ἀξιωμα*), and truth or falsity was ascribed to it, not to the sentence. Statements naturally received most attention from the Stoic logicians, but they recognized many other varieties of complete lekta as well. The fact that they did so strongly suggests that they had developed other categories of completable lekta too, for most of the other complete lekta cannot be analyzed into subject and predicate. Among the other varieties were commands, prohibitions, yes-no questions, questions requiring more than “yes” or “no,” curses, prayers, doubts (“Can it be that life and pain are akin?”), and quasi statements (“How like to Priam’s son the cowherd is!”) (*Adversus Mathematicos* 8.71–73; Diogenes Laërtius 7.65–68).

Since these are categories of incorporeal lekta rather than of sentences, they cannot be identified with strictly grammatical categories. Moreover, although some of the distinct lekta do correspond to grammatically distinct sentences—for instance, the two kinds of questions—many of them do not. The Stoics’ own example of the kind of lekton called a doubt was expressed in what is grammatically a yes-no question; commands and prohibitions get expressed in declarative as well as in imperative sentences, and occasionally both may be expressed in one and the same sentence, for example, “Abstain from strong drink.” Thus Plutarch reports, in his attack on the Stoics, that “they themselves maintain that those who for-

bid *say* one thing, *forbid* another, and *command* a third. For he who says ‘you ought not to steal’ forbids stealing and commands not stealing at the same time as he says you ought not to steal” (*On the Contradictions of the Stoics* 1037d).

As many as three different complete lekta may, then, be associated with a single sentence, and those lekta are obviously not to be identified as thoughts or intentions on the part of the speaker or hearer. Nor does it seem likely, despite Plutarch’s way of presenting the doctrine, that all the complete lekta associated with a given sentence must be expressed whenever the sentence is uttered. Besides being far-fetched, that requirement would ignore the sense of *expressibility* built into the Stoics’ technical term “lekton.” Instead, the Stoic doctrine seems to be that a number of distinct linguistic jobs—such as stating, commanding, prohibiting—can be performed by means of a single sentence, depending on which of the complete lekta associated with that sentence is actually communicated on a given occasion of its use. Thus the three lekta associated with the example given by Plutarch may be presented as (1) the statement that one ought not to steal, (2) the command not to steal, and (3) the prohibition of stealing. It seems to be a discovery of the Stoics (and their greatest contribution to semantics) that the explication of meaning involves not only the things we talk about and the thoughts we express but also the jobs we do by means of language alone.

THE EPICUREANS

Of the Stoic semantic triad—linguistic sign, what is conveyed thereby (the lekton), and external object or event—the Epicureans accepted only the first and third, ascribing truth and falsity directly to spoken sentences (Sextus Empiricus, *Adversus Mathematicos* 8.13). This rejection of the lekton is typical of the Epicureans’ mistrust of any doctrine that went beyond the evidence of the senses. Plutarch describes them as “completely doing away with the category of lekta, leaving only words and objects and claiming that the intermediate things conveyed by the signs simply do not exist” (*Adversus Coloten* 1119F), but there is also a vague suggestion that they may have found it convenient to provide “lekta” as dummy referents in one important kind of case. “They deprive many important things of the title of ‘existent,’ such as space, time, and location—indeed, the whole category of lekta (in which all truth resides); for these, they say, are not *existents* [*ὄντα*], although they are *something* [*τινά*]” (*Adversus Coloten* 1116B).

In stating their atomist metaphysics, the Epicureans were of course obliged to use such words as “space” and “time,” and it looks as if they may have clumsily attempted to provide referents for them by associating only such words, or sentences containing such words, with lekta. However, even if they did maintain that there are two kinds of referents for words, real things and lekta, the latter to be invoked only in case the former are unavailable and the words are indispensable, there is nothing of the *Stoic* lekton in their doctrine.

Aside from this putative special use of special lekta, the Epicureans’ philosophy of language seems to have remained remarkably faithful to their fundamental sensationalism. Epicurus (341–270 BCE) had originally stressed the importance of beginning the study of physics (one of the main branches of Epicurean, as of Stoic, philosophy) by ascertaining the ultimate referents (*ὑποτεταγμένα*) of words, “so that our proofs may not run on untested indefinitely nor the terms we use be empty. The primary intent (*ἐννόημα*) of every term employed must be clearly seen and ought to need no explication” (Diogenes Laërtius 10.37–38); and he went on to claim that these ultimate referents must then be “our sensations,” “present impressions,” “actual feelings.” These are always veridical since their immediate causes are the *eidola*, and thus “the agent productive of each of them is always entirely presented and, as being presented, it is incapable of being productive of the presentation without being in very truth as it appears.... Thus the visible object not only appears but actually is as it appears.... The presentations that occur are, then, all true” (Sextus Empiricus, *Adversus Mathematicos* 7.203–204). The square tower in the distance appears round, but its round appearance is itself a physical object, an *eidolon* detached from the tower and impinging on the apparatus of sight. If I say, then, “the tower is round,” I may (and in this case I shall) be mistaken, since the tower is not the immediately presented object. But if I say “the appearance (or presentation) of the tower is round,” I cannot be mistaken (at least not in that same way). Although this is a move in the direction of protocol sentences, it does not rest on a distinction between sense-datum and physical-object sentences, since for the Epicureans the protocol sentence was only a more correctly framed physical-object sentence.

No full account of this Epicurean reductivism is extant, but its principle is clearly operative not only in their physics but in their ethics as well, where one pervasive maxim for the avoidance of fear is to reduce the mysterious (for example, in natural phenomena) to what is

actually presented and to describe it in terms precisely associated with the features of the actual presentation (see, for instance, Diogenes Laërtius 10.78 ff.).

Epicurus’s followers evidently took the nature of the relation between words and sensations as a major topic for psychological theory. The notion of *prolepsis* is at the center of the Epicurean psychology, and in at least one of its many guises *prolepsis* seems to be the act of associating a word with a *typos*, or outline left in the mind as the result of repeated similar presentations. One example of *prolepsis* is the identification “such and such a thing is a man”—“for no sooner is the word ‘man’ uttered than we think of the *typos* of man in accordance with the *prolepsis*, the senses having led the way. As a result, the immediate referent of every name is apparent.... Nor would we have given a name to anything if we had not first come to know the *typos* of it in accordance with *prolepsis*” (Diogenes Laërtius 10.33).

The *typos*, then, is the immediate referent (*τὸ πρῶτως ὑποτεταγμένον*) of every name. When a name is used and understood, an act of *prolepsis* at once brings the corresponding *typos* to mind. (Since nothing but sensation can produce a *typos*, the need for some other sort of referent in the case of words such as “space” and “time” is apparent.) If this was indeed the core of the Epicurean semantics of words, it must be judged inferior to many other theories of its kind in antiquity.

Epicurus himself and the Epicureans generally had a good deal to say about the origin of language, and what they said usually makes better sense than most such accounts in antiquity. Lucretius (99–55 BCE) is especially good on this topic, which he treated at some length in Book V of his poem. Among his more novel and interesting achievements is an extended series of arguments against the theoretical possibility that language (as distinguished from *a* language) might have been *invented* (*De Rerum Natura* 5.1041 ff.).

THE MIDDLE AGES

ST. AUGUSTINE

Most of what St. Augustine (354–430) had to say about language and meaning was said not for its own sake but in support or elucidation of some theological doctrine. Partly for that reason, perhaps, his semantic doctrines had less effect on philosophy of language in the Middle Ages than might be expected, considering his enormous influence on medieval philosophy in general.

The short treatise *Principia Dialecticae* (probably written around 384, when Augustine was a professor of rhetoric) contains what may be the only instance of a semantic inquiry pursued by Augustine without a motive. In it he distinguishes four principal semantic elements: (1) the word (*verbum*), a spoken articulate sound, classifiable as a vocable of some language; (2) the expressible (*dicibile*), “whatever is sensed in the word by the mind rather than by the ear and is retained by the mind”; (3) the ordinary use of the word (*dictio*), (opposed, for instance, to the use of the word as a sign for itself), which involves “both [1] the word itself and [2] that which occurs in a mind as the result of the word” when the word occurs “not on its own account but on account of something else that is to be signified”; (4) the signified thing (*res*), which may be “something understood, or sensed, or inapprehensible”—the last category reserved for, for instance, God and formless matter (Ch. 5). Of these four elements, (2) and (3) together seem to represent different aspects of the Stoic lekton; but whatever their origin, their inclusion here indicates a level of sophistication in semantics that was not to be attained again for at least eight hundred years.

Chapter VII of the *Principia Dialecticae* is devoted expressly to the “import” (*vis*) of words. In it Augustine maintains that “the import of a word is that whereby the extent of its efficacy is recognized [*qua cognoscitur quantum valeat*], and it is efficacious to the extent to which it can affect a hearer.” Import is a broader notion than signification and includes several sorts of effects a given word may have because of its sound, its degree of familiarity to the hearer, its degree of admissibility into polite conversation, its being recognized by the learned hearer as a dactylic foot or as some particular part of speech, and so on. The paradigm case of signification is described as occurring “on an occasion when a sign has been comprehended through a word [and] the mind regards [*intuetur*] nothing other than that very thing the sign it comprehends is a sign of. Suppose, for example, that Augustine has been named and someone to whom I am known thinks of nothing other than myself, or that some other man named Augustine comes to mind if the name happens to be heard by someone who does not know me but knows that other man.” The most remarkable and apparently novel features of this brief account are (a) the extension of the notion of meaning in Augustine’s doctrine of “import” and (b) the orientation of his account of meaning around the effects words have on their hearers. The remainder of the treatise deals with simple and conjoined words and sentences, etymology, and various types of ambiguity and obscurity.

The longest of Augustine’s discussions of semantic questions occurs in the dialogue *De Magistro* (389), which is designed ultimately to support the Augustinian doctrine of “divine illumination” as the sole genuine source of truth. Thus the first 11 chapters are supposed to show that “we learn nothing through those signs that are called words” (Ch. X), while chapters XI–XIV develop the thesis that Christ, the truth, teaches us inwardly while men by their use of outward signs merely prompt us to raise questions. The argument in support of the negative conclusion is an outstanding example of overemphasis on the word as the unit of signification. “When words are uttered, either we know or we do not know what they signify. If we know, then we do not learn but are reminded. If, on the other hand, we do not know, then we are not even reminded (though we may be prompted to ask)” (Ch. XI). Therefore, “we learn nothing through those signs that are called words”—as if one’s knowing what the words mean in “armadillos are mammals” precluded one’s learning anything through hearing that sentence uttered. At this crucial juncture in the dialogue Augustine’s ulterior motive seems to have distorted his judgment.

Perhaps the most interesting point in the early chapters of *De Magistro* is one that bears on the best-known Augustinian passage on language, the description of his learning to speak in *Confessions* (397), 1.8, made famous by Ludwig Wittgenstein’s use of it in *Philosophical Investigations* (Sec. 1). The passage in the *Confessions* can hardly be considered a theoretical statement at all, since Augustine’s main aim in it is to describe a milestone on his descent “into the stormy fellowship of human life,” but it does contain a brief, uncritical account of one way in which a child might be shown “the things of which words are signs.”

That this account cannot be considered important in the context of Augustine’s own views on language is plain from the fact that he had already criticized just such an account on theoretical grounds in *De Magistro*. In an attempt to refine the original suggestion of the dialogue that a sign cannot be a sign “unless it signifies something” (Ch. II), Augustine asks to be shown “that one thing itself, whatever it is, which is signified by these two words,” *ex* and *de*, Latin prepositions there taken to be synonymous. After several obviously unsuitable suggestions, the tentative conclusion is reached that not only in these problematic cases but also in every case of attempting to show “the thing signified,” all that can be shown is further signs, such as other words, pointing, pantomiming. This criticism is of course not the same as Wittgenstein’s, nor is it

particularly far-reaching in its own right, since it is soon modified to allow that we can in certain cases display the very thing signified without the use of further signs—for instance, if the thing signified is something we are able to do (such as walk) and we are not in the act of doing it when asked to display the thing signified (Ch. III).

A rather fully developed semantic theory appears in the *De Trinitate* (399–419), especially in 9.7–12 and 15.10–16, although it is presented no more for its own sake than is the theory in *De Magistro*. The theory appears as the explanatory half of an ingenious analogy designed to clarify (a) the relation between the First and Second Persons of the Trinity, (b) the two natures of the Second Person, and (c) the identification of the Second Person as the Word. The analogical points may be ignored for present purposes and the semantic doctrine sketched as follows. “Word” has at least two senses. “In one sense, those things are called words that occupy intervals of time with syllables, whether they are pronounced or only thought. In another sense, everything that is known is said to be a word impressed on the mind as long as it can be brought out of memory and defined” (9.10). (Augustine actually introduces a third sense involving the love of what is known, but it seems pointless except for purposes of the analogy.) The second kind of “word,” which Augustine describes more generally as a “locution” when the demands of the analogy are not uppermost in his mind, occupies the central position in the doctrine. “The word that sounds outwardly is a sign of the word that gives light inwardly, and the name ‘word’ is better suited to the latter; for what is uttered by the mouth of the flesh is the articulate sound of the word [*vox verbi*]; ... [thus] our word becomes an articulate sound ... by taking on [articulate sound], not by consuming itself so as to be changed into it” (15.11).

The doctrine of the inward locution sometimes bears a striking resemblance to Plato’s doctrine of ideal names in the *Cratylus*, although a direct historical connection seems unlikely. “For of necessity, when we say what is true—i.e., say what we know—the knowledge itself, which we retain in memory, gives birth to a word that is altogether of the same kind as the knowledge from which it is born. For the thought formed by the thing that we know is a word that is neither Greek nor Latin nor of any other language. But since it is necessary to convey it into the knowledge of those with whom we speak, some sign is adopted by which it is signified” (15.10; cf. *Sermo* 225.3). According to this doctrine, then, it seems that one’s saying “armadillos are mammals” embodies in sounds one’s inward locution to that effect, which itself

differs from one’s knowledge that armadillos are mammals only in being brought out of memory into conscious thought. Augustine sometimes suggests that the inward locution, then, is not itself verbal; words used in the mind are not essentially different from words outwardly pronounced, as Augustine’s first division claims. Indeed, the inward locution is evidently less a mental entity than the state of consciousness into which a mental entity, namely, a known truth, must be brought if it is to be given verbal expression.

BOETHIUS

As an original contributor to semantics, Boethius (480–524) is much less interesting than Augustine. Since, however, his translations and commentaries constituted the sole source of Aristotelian logic for the medievals until the twelfth century, Boethius’s influence over the development of semantics in the Middle Ages is powerful where Augustine’s is slight.

Most medieval semantic theories take as their starting point Boethius’s translation of the rudimentary account in Aristotle’s *De Interpretatione*, Chapter 1. No doubt the traditional misreading of those passages during and after the Middle Ages is largely the result of the fact that in his otherwise faithful rendering Boethius obliterated the Aristotelian distinction between symbols and symptoms, translating both *σύμβολα* and *σημῖα* as *notae*. Another of the principal difficulties in Aristotle’s account—the apparent interposition of “mental modifications” between words and things—had been discussed at least as early as the third century by Alexander of Aphrodisias, whose confusing resolution of the difficulty was transmitted to the medievals in Boethius’s second commentary on the *De Interpretatione*. Alexander had asked whether Aristotle’s account forces us to consider the mental modifications as names of things. In order to avoid that consequence he had developed the view that although “a name is imposed on a thing” and “although spoken words are names of things, nevertheless we use spoken words not in order to signify things, but in order to signify those mental modifications that are produced in us as a result of the things. Therefore, since spoken words are uttered for the purpose of signifying those entities, he [Aristotle] was right to say that they are primarily the signs [*notas*] of those entities” (413A–B; all references in this section are to *Patrologia Latina*, edited by J. P. Migne, Vol. 64).

Perhaps the most influential doctrine (at least in the late Middle Ages) that can be traced directly to Boethius’s treatment of *De Interpretatione*, Chapter 1, is that of the

three discourses: written, spoken, and mental. Citing Porphyry (c. 233–c. 305) as his authority, Boethius reported that “among the Peripatetics there were said to be three discourses [*orationes*]—one written in letters, another uttered in speech, and a third put together in the mind. Now if there are three discourses, the parts of discourse are no doubt likewise threefold; for since the noun and the verb are the principal parts of discourse, there will be some nouns and verbs that are written, others that are spoken, and still others that are silent and employed by the mind” (407B–C). Here, as in his transmission of the Aristotelian account itself, the vagueness of Boethius’s presentation is as important historically as its content. Are there two completely different sets of nouns and verbs, one for writing and one for speech? And is this mental discourse nothing more than silently running over a sentence in Latin or English, Or is it a nonverbal operation, reminiscent of Augustine’s “inward locution”? The fact that mental discourse is said to have nouns and verbs of its own suggests the former view, if either; but since Aristotle had maintained that the mental modifications were the same for all (regardless of their native tongue), and since Boethius offers this doctrine of the three discourses in explanation of Aristotle’s account, there is some basis for the second view as well. These were among the difficulties discussed in the medieval development of the doctrine.

The medieval distinction between words of first and second “imposition,” a genuine prefiguring of the twentieth-century distinction between object language and metalanguage, also has its roots in Boethius’s transmission of older doctrines. In his commentary on Aristotle’s *Categories* he presents the distinction very much as he found it in Porphyry’s *Expositio* of the same work (A. Busse, ed., pp. 57–58). “The first imposition [*positio*] of a name is made with respect to the *signification* of the word, the second with respect to its *form*” (159C). Thus, whenever some extralinguistic entity is called a man, it is a case of first imposition. “But when the word ‘man’ itself is called a noun, no reference is made to the signification of the word [Boethius has ‘noun’], but to its form, in virtue of which it admits of inflection by means of [grammatical] cases” (159B–C). Thus “noun” in its ordinary use is a word of second imposition.

In this primitive form the distinction seems to apply only to the grammarian’s kind of interest in discourse. Boethius, however, took the position that “the whole art of logic is concerned with discourse” (161C–D). How does the philosopher’s interest in language differ from the grammarian’s? Very much as the economist’s interest in

money differs from the numismatist’s, for Boethius compares the signification of a word to the buying power of a coin and its grammatical form to the “bronze stamped with a design.” Consider “an utterance that designates nothing, such as ‘gargulus.’ Although the grammarians, considering its form, contend that it is a noun, philosophy does not recognize it as a noun unless it is imposed in such a way as to designate a conception belonging to a mind (in which same way it can signify some real thing)” (408C–D). Apparently, then, second imposition needs to be more broadly conceived, or a philosopher’s kind of second imposition must be added to the kind described by Boethius. The resolution of such difficulties was among the goals of the later doctrine of the impositions and “intentions” of words.

By far the most influential of Boethius’s bequests to the Middle Ages was his formulation of the problem of universals in his second commentary on Porphyry’s *Isagoge*. Needless to say, a great many semantic issues were discussed in the long controversy over universals, and a few of the more important ones will be noted below. Boethius’s formulation of the problem, however, was oriented around questions of metaphysics rather than of semantics and so may be passed over here.

ST. ANSELM

One of the semantic problems recognized by the early medievals in the few logical works of Aristotle available to them was the problem of paronyms, or denominatives. Its principal source is the following passage in the *Categories*, Chapter 8 (10a27 ff.). “These, then, that we have mentioned are qualities, while things called paronymously because of these or called in some other way from them are qualified. Now in most cases, indeed in practically all, things are called paronymously, as the pale man from paleness, the grammatical from grammar, the just from justice, and so on.”

St. Anselm (1033–1109) remarks at the end of his dialogue on denominatives—*De Grammatico*—that the semantics of denominatives was a favorite topic among dialecticians of the eleventh century, evidently because of the difficulty of developing a satisfactory account of denominative words that occur both as concrete nouns and as adjectives. (Anselm’s chief example is *grammaticus*, but because the English word “grammatical” is not a denominative of this sort, “illiterate” will be used here.) Thus, the opening question of Anselm’s dialogue is whether “illiterate” signifies a substance or a quality. This seems to be a narrow, perhaps artificial problem, but

under his characteristically ingenious treatment it leads to results of general importance.

The superficially most plausible solution to the problem is that such a word sometimes signifies a substance—as in “not every illiterate is stupid”—and sometimes a quality (illiteracy)—as in “not every illiterate person is stupid.” This solution is shown to fail, however, at least in its second half, for if we tried to use “illiterate” alone in speaking about the quality—as in “illiterate is a deplorable condition”—“not only the grammarians would be upset, but even the peasants would laugh” (Ch. XI). “Illiterate,” we must recognize, “does not signify a person and illiteracy as a unit [*ut unum*] but signifies illiteracy directly [*per se*] and a person indirectly [*per aliud*]” (Ch. XII). Another way to put the distinction between the two kinds of signification is to say that “illiterate” is *significative* of illiteracy and *appellative* of a person. “I now describe a name as appellative of each thing itself that is called [*appellatur*] by that name in the speaker’s usage; for there is no speaker’s usage in which ‘illiteracy is illiterate’ occurs, ... but rather ‘the person is illiterate’” (Ch. XII).

The remainder of the dialogue refines and generalizes this account in the course of dealing with various objections to it. Anselm’s most original and important contributions seem to be those developed mainly in the last two chapters (where the discussion centers around *albus*—“white”—rather than *grammaticus*). The Master of the dialogue has suggested that “white” signifies (rather than appellates) nothing but being in possession of whiteness (*habens albedinem*). This is disturbing to the Student, who feels the need of a signified *thing*. “White,” he is willing to grant, “does not determinately signify this or that possessing entity, such as a body,” but he wants to insist that it “indeterminately signifies something possessing whiteness.” His principal argument is that “‘white’ signifies either something possessing whiteness or nothing; but one cannot conceive of nothing as possessing whiteness; therefore it is necessary that ‘white’ signify something possessing whiteness” (Ch. XX).

In reply Anselm takes the position that while it may always be the case that what is signified somehow depends for its being on some real thing, it cannot always be the case that what is signified is a thing. His arguments for this position display an interesting use of the principle of substitutivity.

If “white” signified a thing at all, it would signify something white. Now the signification of a word is what its definition presents, and what is presented by the definition may be substituted for the word itself. “So wherever ‘white’ is used it is taken correctly as ‘something

white’” (Ch. XXI). Then “Socrates is white” may be rewritten as “Socrates is something white.” But “wherever ‘something white’ is used it is also correctly said twice—‘something something white’—and wherever it is said twice, there also three times, and so on indefinitely” (Ch. XXI). Thus the plausible “Socrates is something white” would become the nonsensical “Socrates is something something white” and would ultimately lose all semblance of a statement.

Instead, in “Socrates is white,” “white” appellates something white—Socrates himself—but what it signifies is being in possession of whiteness. Nor will it do to introduce a signified thing at this point, for if we take something in possession of whiteness to be what “white” signifies, we shall have to grant that something in possession of whiteness is that which is white. “If, therefore, ‘white’ is ‘that which is white,’ it is also ‘that which is that which is white’; and if it is that it is also ‘that which is that which is that which is white,’ and so on indefinitely” (Ch. XXI). The nonsense-engendering substitutions cannot be made within “being in possession of whiteness,” however, since the denominative “white” does not itself occur in it. Thus “it is clear enough that ‘white’ does not signify something in possession of whiteness ..., but only being in possession of whiteness—i.e., [the categories] *quality* and *possession* [and not the category *substance*]—and quality and possession by themselves make up no *something*” (ibid.). This argument is described as holding good for all single words that, like “white,” signify “a plurality [of categories] out of which no one thing is made up” (Ch. XXI).

Although the special consideration of denominatives apparently lost its vogue soon after Anselm, many of the problems dealt with in his *De Grammatico* remained current and can be found two centuries afterward at the center of the theory of the properties of terms (see below).

ABELARD

The extensive logical writings of Peter Abelard (1079–1142) are best known for the theory of universals developed in them. That theory is important in the history of semantics because (a) it explicitly approaches the problem of universals as a semantic rather than a metaphysical problem and because (b) in doing so it introduces many of the elements of the semantic theories developed by the terminist logicians of the thirteenth and fourteenth centuries.

Regardless of how the problem of universals is approached, it involves a consideration of the semantics of words, especially of common names. Nevertheless,

many of the countless medieval theories, in their preoccupation with the Porphyrian-Boethian questions about the existential status of genera and species, slighted or ignored the semantic issues. Abelard, on the other hand, began by adding a new semantic question to the three traditional metaphysical questions. “Could a universal consist of the signification of a concept [*significatio intellectus*] when the things named were destroyed, as [in winter] when there are no roses to which the name ‘rose’ is common?” (*Logica “Ingredientibus,”* edited by B. Geyer, p. 8).

Having associated universals with words, Abelard asked “whether they are associated *only* with words or with things as well” (p. 9). Applying the Aristotelian criterion *predicability of more than one thing*, he showed in a series of elaborate arguments that a universal cannot be identified as (1) a single thing or (2) a collection of things (pp. 10–16). His principal objection really avoids the issue of whether or not it makes sense to speak of a thing or a collection as predicable at all and concentrates instead on the impossibility of predicating a thing or a collection of more than one thing. Thus “it remains for us to ascribe universality of that sort to words [*vocibus*] alone” (p. 16). As Abelard came to realize, words considered as utterances or inscriptions are themselves things. Accordingly he eventually distinguished between utterances [*voces*] and words [*sermones*] and organized his theory of universals around words in this strict sense—*sermo = vox + significatio*—which he described as products of human arrangements rather than mere natural effects (*Logica “Nostorum Petitioni Sociorum,”* edited by B. Geyer, p. 522).

The only kind of word to which universality can conceivably be ascribed is the kind of word apparently predicable of more than one thing, that is, a common name in the nominative case. But that ascription cannot mean that the common name has some universal thing as its bearer, for, as he had shown, “universal thing” is a contradiction in terms. Nor can some particular thing be picked out as its bearer, for although it *may be* Socrates alone of whom the statement “a man is sitting in this house” is true, we cannot *infer* from it that Socrates is sitting in this house (p. 18). These considerations led Abelard to base the ascription of universality not on what the words name (*nominare*)—for example, “man” names each and every individual thing that is a man—but on their “mode of signification”; for although they name things that are discrete, they do so not “discretely and determinately” but “confusedly” (p. 29).

Abelard’s explanation of this notion of confused naming, which was to play an important part in thirteenth- and fourteenth-century theories of the properties of terms, seems incomplete but runs along the following lines. “To signify is to establish [*constituere*] a concept” (p. 136), and “when I hear ‘man’ ... I do not recall all the natures or properties that are in the things subject [to that name]; instead, as a result of [hearing] ‘man’ I have a conception of animal, rational, and mortal, though not of subsequent accidents as well, [a conception that is] confused rather than discrete” (p. 27). Thus Abelard’s answer to his additional semantic question is a qualified “yes.” In winter the name “rose” lacks universality in that there are no things of which it is predicable, that is, “it is devoid of nomination” (*nominatione*). “Nevertheless, it is still significative then in virtue of the concept [*ex intellectu*]; ... otherwise there would not be the proposition ‘no rose exists’” (p. 30).

Other medieval theories of universals, such as William of Ockham’s, center on semantic doctrines; but Abelard’s “sermonism” was perhaps the most important medieval influence on the development of semantics during the succeeding two centuries of the high Middle Ages. Topics and terminology remained relatively stable in that remarkable period in the history of semantics, although many philosophers and every logician contributed to the discussions. For that reason the remaining material on the Middle Ages is oriented mainly around *topics* in medieval semantics, and no attempt is made to mention every man who discussed them.

IMPOSITIONS AND INTENTIONS

The pervasive medieval distinctions between two levels of signification have attracted some attention in the twentieth century because of their resemblance to the object language–metalanguage distinction. Historically there were two such distinctions, both based on the observation, found already in Porphyry, that while some signs signify nonsigns, others are signs of signs.

The original distinction was drawn with respect to conventional signs, specifically, with respect to names (nouns and adjectives) in a natural language. Such signs acquired their signification only as a result of having been imposed by the users of the language. The primary, or first, imposition was on extralinguistic entities, and names such as “man” and “white” were classified as names of first imposition. As the language developed, other conventional signs were imposed on conventional signs as such; thus, names such as “noun” and “plural” are of second imposition. Names such as “utterance” and “mark”

do signify conventional signs, but not as such (since there are of course nonsignificant utterances and marks); they are therefore names of first imposition. Most medieval logicians, presumably in avoidance of an infinite regress, were careful not to define names of second imposition as names of names of first imposition. Thus “name of second imposition” is itself a name of second imposition.

But even those who, like Abelard (*Logica “Ingredientibus,”* edited by B. Geyer, p. 112), did define second imposition in terms of first seem never to have recognized a “third” imposition. (The imposition distinction, therefore, cannot reasonably be described as prefiguring a hierarchy of types.) The use made of the imposition distinction was apparently rather meager. Aristotle’s categories were, for example, often said to be names of first imposition, while the subject matter of his *De Interpretatione* was described as names of second imposition. The distinction, although it was refined and discussed well into the fifteenth century, seems to have acquired what importance it had mainly from its connection with the later and better known of the two distinctions between levels of signification.

Concepts in their capacity as natural signs were called intentions and described in the doctrine of the three discourses as mental terms. It was only natural, then, to distinguish levels of signification among intentions as among conventionally significant extramental terms. This distinction, probably stemming from Avicenna (see Carl Prantl, *Geschichte der Logik im Abendlande*, 2.328), classified as first intentions all those naturally significant of entities other than intentions as such, while those that did naturally signify intentions as such were second intentions. The concept *humanity* is of course a first intention, but so is the concept *mental entity*. The concepts of the predicables—*genus*, *species*, *differentia*, *property*, *accident*—are second intentions, as is the concept *predicable* itself; no “third” intentions were ever recognized.

Thus first and second intentions and impositions were fundamentally parallel distinctions in separate domains. However, their development in the thirteenth and early fourteenth centuries was complicated (and sometimes confused) by two factors. First, there were, of course, extramental terms imposed on first and second intentions, such as *humanity* and *genus*. Such names were all of first imposition (since no intention was a conventional sign), but they were sometimes further described as names of first or second intention. Second, even more complicating was the fact that the first and second intentions themselves were considered to be terms in mental

propositions. Thus, while in the written proposition “*animal* is a genus” the subject and predicate terms are both of first imposition, in the corresponding mental proposition that *animal* is a genus the subject term is a first intention and the predicate term is a second intention.

Of the two distinctions between levels of signification, the intention distinction had much more philosophical importance. The confusing interrelations of the two distinctions are perhaps best exhibited in William of Ockham (d. 1349), particularly in *Summa Logicae*, 1, 11–12. Logicians after William—for instance, Albert of Saxony (d. 1390), Pierre d’Ailly (1350–1421), Paul of Venice (d. 1428), and Paul of Pergula (d. 1451)—exhibited a tendency to simplify them by reverting to the treatment of impositions and intentions as strictly separate, parallel distinctions. Postmedieval scholastics—for example, John of St. Thomas (1589–1644)—were inclined to apply the intention distinction indifferently to extramental as well as to mental terms and to ignore the imposition distinction; it is in this simplified form that the “medieval” distinction between levels of signification is usually discussed in recent literature.

SCIENTIA SERMOCINALIS

Almost everything genuinely novel in medieval logic is to be found in the theories of the properties of terms and of the functions of syncategorematic words developed by the logicians of the high Middle Ages. One reason why logic set off along that line of logicosemantic inquiries is that medieval logicians, especially through the formative period ending about 1250, thought of their subject as the science of language (*scientia sermocinalis*).

That classification itself marked a break with the Aristotelian-Boethian tradition in that it was precise where the tradition had been vague. The notion of predication was unquestionably an essential part of the subject matter of logic, but Aristotle and Boethius had treated it in ways that often suggested that predicates might be extralinguistic and even extramental entities. This crucial vagueness, which was to some extent also the source of the medievals’ concern with universals, left open the possibility that logic might be essentially a science of reality, resembling or subsumed under metaphysics.

However, in the earliest complete European logic we have after Boethius—the *Dialectica* of Garland the Computist (d. before 1102)—that possibility was already noted and explicitly ruled out. Predication, Garland maintained, occurs only in a proposition, and the only constituents of propositions are utterances; thus, only

utterances may be predicated. The five predicables (genus, species, differentia, property, accident), the elementary subject matter of medieval logic, are, in virtue of being predicables, utterances and no more; and the ten categories (substance, quality, and so on) are likewise categories of utterances only—for instance, noun and adjective (*Dialectica*, edited by L. M. de Rijk, p. 3).

The attempt to establish logic as a science of linguistic entities only may be called sermocinalism. During the years 1150 to 1250, when medieval logic was acquiring its distinctive character, sermocinalism held undisputed sway as the philosophy of logic, but it did so in the refined and strengthened form given it in the writings of Abelard. Garland had attempted to make utterances (*voces*) the elements of logic, which he thought of as the science of language. Abelard, recognizing that utterances are physical events that are, as such, of no interest to logicians, replaced the overly simple utterance with what he called the *sermo*, defined as the utterance taken together with its signification. Logicians in the second half of the twelfth century seem to have been unanimous in their adoption of this refinement. An anonymous *Dialectica seu Logica* supported the rejection of utterances as the elements of logic with the following interesting argument, somewhat reminiscent of Aristotle's doctrine of complex names. "Some utterances are significant; some are not.... This division ... is exhaustive but seems not to be exclusive, since the same utterance may be both significant and not significant. For example, the utterance 'king' [*rex*] is significant as a word, but since it is also part of a word, a syllable of a word—as in 'smoking' [*sorex*, shrew]—it is in that case and on that account not a significant utterance" (Martin Grabmann, *Bearbeitungen*, Berlin, 1937, p. 30).

Having more precisely identified the elements of logic as linguistic entities, Abelard suggested that logic as the science of language should determine significations on the basis of the application of utterances, determining the proper application of utterances on the basis of the investigations of the natural sciences (*Dialectica*, pp. 286–287). One reason for this suggestion seems to have been his concern with propositions true *gratia terminorum*, analytically true on semantic rather than on syntactic grounds—for instance, "if there is paternity, there is filiation" or "if it is a body, it is corporeal" (see pp. 284–286).

To most medieval philosophers Abelard's emphasis on the importance of signification as well as of utterance might have suggested that mental entities of some sort were to be considered the elements of logic. He explicitly rejected this possibility, however, and in doing so made

his most important contribution to sermocinalism. He argued that a proposition true *gratia terminorum* could not be verified by an appeal to the status of mental entities. "When we say 'if it is man it is animal,' if we refer to the connection of the *understanding* of the propositions, as if we were concerned with the *concepts*, there is no truth to the conditional, since the one *concept* may occur entirely without the other" (p. 154). What we are concerned with, Abelard maintained, is the connection between the term *animal* and the definition of the term *man*—namely, the inclusion of the term *animal* within the string of terms making up the definition of the term *man*. As a result of this move, sermocinalism was directed not only against the notion of logic as a science of reality (*scientia realis*) but evidently also against the notion of it as the science of reason (*scientia rationalis*).

The philosophy of logic that eventually challenged sermocinalism concentrated its opposition on this last point. Since it was explicitly drawn from the philosophy of Avicenna, the rival doctrine may conveniently be called Avicennianism. Although as many of Avicenna's writings as were available to the medievals had been translated into Latin around the middle of the twelfth century, Avicennianism as a philosophy of logic seems not to have come into prominence until Albert the Great (1193–1280) adopted it around the middle of the thirteenth century. By that time, however, medieval logic was firmly committed to its distinctive line of development as the *scientia sermocinalis*. As a result, the main impact of Avicennianism as an alternative to sermocinalism was felt less on the work of the logicians than on the metaphysicians' discussions of the nature of logic.

The central doctrine of Avicennianism is presented in the frequently quoted passage from Avicenna's *Philosophia Prima*: "The subject matter of logic, as you know, is intentions understood *secondarily*, which are applied to intentions *primarily* understood" (I, 2, f70vA). Logic was the science of reason, Avicenna claimed, for "the relation of this doctrine [logic] to internal thought, which is called internal speech, is just like the relation of grammar to outward signification, which is called speech" (*Logica* f3rA). Thus grammar, not logic, was the sermocinal science, according to Avicennianism, and the rise of speculative grammar that was to follow may in part be attributed to this point of view.

THE PROPERTIES OF TERMS

Until about the middle of the twelfth century the subject matter of medieval logic was drawn from Aristotle's *Categories* and *De Interpretatione*, together with a set of

books by Porphyry and Boethius that were centered more or less closely on those two books of Aristotle. Later in the Middle Ages this collection of books, or the kind of logic these books contained, became known as *logica vetus*, the old logic. When the remaining four books of Aristotle's Organon began to circulate in western Europe during the twelfth century, they, or their contents, became known as *logica nova*, the new logic. The only completely new kind of material in the *logica nova* was the treatment of fallacy in Aristotle's *Sophistical Refutations*, which excited a tremendous interest in *sophismata*, fallacies resulting from the misuse of or natural ambiguities in various devices of ordinary discourse. Largely because of this lasting interest, medieval logicians of the late twelfth and early thirteenth centuries gradually developed an original logicosemantic inquiry. In order to distinguish this genuinely medieval contribution from Aristotle's contributions to logic, thirteenth-century philosophers began to speak of it as the *logica moderna*, lumping the *logica vetus* and *logica nova* together as *logica antiqua*. Perhaps the *logica moderna* was aimed originally at nothing more than providing ad hoc rules of inference to cover problematic locutions in ordinary discourse, but, although it retained that aim throughout its three-hundred-year history, its principal aim soon became the development of a reasonably general account of the different ways in which words are used to stand for things and to operate on other words.

The earliest known fully developed productions of the "modernist" or "terminist" logicians are the logical treatises of William of Sherwood (d. 1266/1272), Peter of Spain (d. 1277), and Lambert of Auxerre (fl. 1250), evidently written at Paris about the middle of the thirteenth century. At that time the *logica moderna* seems to have been thought of as having two branches, an account of "the properties of terms" (*proprietas terminorum*) and an account of the signification and function of "syncategorematic words" (*syncategoremata*). The two branches naturally differed in detail, but both accounts employed the same principles of explanation and had the same aims. Most nouns, pronouns, verbs, participles, and adjectives were considered to be categorematic words, words capable of serving as terms (that is, as subjects or predicates); and the syncategorematic words were those which can occur in a statement only together with categorematic words. The two branches of the *logica moderna* were thus theoretically exhaustive of the kinds of words occurring in various roles in statements.

The modernists of the thirteenth century regularly recognized four properties of terms: (1) signification—

the word's meaning, broadly conceived, or the range of conventional uses of the word (a property of every categorematic); (2) supposition—the conventional interpretation of a word on a particular occasion of its use, a modification of its signification resulting from its syntactic context, if any, and other considerations (a property only of nouns, pronouns, and "substantive expressions," that is, other categorematics employed as substantives and particularly as subjects); (3) copulation—virtually the same as supposition, except that it is a property only of verbs, participles, and adjectives, especially when they occur as predicates; (4) appellation—"the present correct application of a term" (Sherwood), a property only of nouns, adjectives, and participles; for instance, in 2004 Chicago was an appellatum of "city" but Nineveh was not.

Obviously these four properties are not on an equal footing. The supposition, copulation, or appellation of a term was considered a function of its signification; Vincent of Beauvais (d. 1264) even designated signification the genus of which the other three are species (Carl Prantl, *Geschichte der Logik*, Vol. III, p. 83, n. 319). Moreover, copulation and appellation are of distinctly secondary importance. By the middle of the fourteenth century only signification and supposition were regularly recognized as properties of terms, and throughout the history of the *logica moderna* it was the supposition (*suppositio*) of terms on which the inquiry centered. For that reason the best way of quickly acquiring a broad but accurate idea of the modernists' account of the properties of terms is to examine their divisions of supposition. (The recognition and treatment of the divisions of course differed from one modernist to another, but the following selection includes all the major divisions and many of the more interesting minor divisions.)

The supposition of a term was divided initially into *proper* and *improper* supposition. A term had improper supposition when it was used figuratively, and several varieties of improper supposition were distinguished: antonomastic, synecdochic, metaphoric, ironic, and metonymic. The proper supposition of a term was divided into *formal* and *material* supposition, the latter being the use of a term to refer to itself, either as type or as token—for instance, "man is a noun," "man is an animal" is a true statement," "man is a monosyllable," "man has three letters." Formal supposition was *personal* if the term was used to refer to individuals bearing the form signified by the term, *simple* if the reference was to the form itself, as in "man is a species." The initial division of personal supposition was sometimes based on the divi-

sion of terms as *common* or *discrete*, depending on the possibility of using them to refer to more than one individual at a time. Thus, the subjects of the statements “Socrates is running” and “that man is running” have discrete personal supposition.

The portions of supposition theory dealing with the divisions of the personal supposition of common terms were more fully developed than the rest, not only because they were intrinsically more interesting but probably also because they provided the most points of contact between the *logica antiqua* and the *logica moderna*. In those portions of supposition theory, far more than in the others, the emphasis lay on the application of the theory to the evaluation of inferences, especially such inferences as involved Aristotle’s four categorical propositions (or near relatives of them) but could not be adequately evaluated within the *logica antiqua*.

A common term was said to have determinate personal supposition when it was used to refer to some one individual without identifying the supposed individual, as in “a man is running” or in “some man is running.” A statement including a “distributive sign” (such as “every” or “no”) was, on the other hand, bound to include one or more common terms having *confused* personal supposition, terms used to refer to more than one individual at once or to one individual many times (as in “every man sees a man,” where the second occurrence of “man” has confused supposition even if it is being used to refer to only one individual). If the confused supposition included each and every individual bearing the form signified by the common term, it was designated *distributive*, as in “every man is an animal,” “no man is an ass.” If the confused supposition did not plainly include that totality, it was designated *merely confused* (*confusa tantum*), as in “every man is an animal,” “every man sees a man.”

The modernists observed that in many cases of distributive confused supposition it was possible to make a “descent” under the term having such supposition, instantiating as in “every man is an animal, therefore this man is an animal”; “no man is an ass, therefore no man is this ass.” They described such cases as *mobile* but paid at least as much attention to the *immobile* distributive supposition produced by the use of “exclusives” or “exceptives” together with distributive signs. Thus, in “only every man is running” the distributive supposition of the common term is immobilized by the exclusive “only,” so that one cannot infer “therefore only this man is running.” It was also recognized that the inclusion of the distributive sign within the scope of the exclusive or

exceptive was not always dependent on their relative positions in the statement, since from “every man except Socrates is running” one cannot infer “therefore this man except Socrates is running” (although this unacceptable inference is uninterpretable rather than invalid).

Supposition theory was an attempt to develop a unified treatment of a great number of semantical and logical topics that are still of interest, although now for the most part they are treated in separate inquiries. It is therefore especially intriguing and difficult to discover just what that unifying notion—supposition—amounted to. One broad description that plainly holds good for most of the divisions of supposition is that they are syntax-dependent referential functions of a term’s signification. Any description in terms of syntax and semantics will, however, fail to cover all the divisions of supposition and will miss what is distinctive in it. In the case of improper supposition, for example, while the circumstances under which a term is used clearly do determine whether or not it is being used figuratively, it will not do to limit those circumstances to the syntactic context of the term’s use.

Again, supposition theorists frequently remarked on the fact that the supposition apparently determined by the syntax often differs from the supposition intended by the framer of the statement. The man who visits his friend’s garden and says “this plant grows in my garden” says what is false “with respect to discourse” (*de virtute sermonis*), but the circumstances of his utterance show that he intends to use the word *plant* as in the statement “such a plant grows in my garden.” The correct analysis of the supposition of “plant” takes it to have the supposition determined for it *not* by that syntactic context but by the clearly discernible “intention of the framer” (*intentio ponentis*). Finally, among later supposition theorists it was a matter of controversy whether terms occurring in statements written in a closed book had any supposition at all, and those few who held that they did then have supposition seem to have been motivated by a misguided concern that otherwise certain true statements in a closed book, such as “God exists,” might cease to be true while the book remained unread.

The consensus of the modernists seems to have been that a term had one or another kind of supposition only on an occasion of its actually being used in referring (or understood to have been used in referring) to some entity or entities, the particular kind of supposition being determined by a number of the circumstances of the occasion and its syntactic context being the most important but not in itself the decisive circumstance.

SYNCATEGOREMATA

Within the *logica moderna* the investigation of syncategorematic words complemented the investigation of the categorematic words under the doctrine of “the properties of terms.” Something closely resembling the modernists’ notion of syncategoremata seems to have been operative in Aristotle and the Stoics, but the medievals evidently acquired the technical term and the rudiments of the notion directly from Priscian (fl. 500), who had reported that “according to the dialecticians [not identified], there are two [principal (?)] parts to a sentence—the noun and the verb—since they alone and of themselves make a sentence; but they called the other parts *syncategoremata*—that is, consignificants” (*Institutio de Arte Grammatica*, M. Hertz, ed., in H. Kiel, *Grammatici Latini*, Leipzig, 1855, Vol. II, p. 54).

Interest in the syncategoremata as such began in connection with the twelfth-century interest in fallacies of ambiguity as it became plain that the crucial ambiguity was often located elsewhere than in subjects and predicates. The grammatical basis of distinction provided by Priscian seems to have been adopted at first and occasionally even narrowed so that only the “indeclinables”—prepositions and conjunctions—were considered to be syncategoremata (see the anonymous late twelfth-century *Fallacie Parvipontane*, edited by L. M. de Rijk, in *Logica Modernorum*, Vol. I, p. 559; also see Abelard, *Dialectica*, edited by L. M. de Rijk, pp. 118–121). The notion of syncategoremata that became important in the *logica moderna*, however, was not founded on a strictly grammatical distinction. Abelard’s treatment of “alone” in “a man alone is capable of laughter” (*Logica “Ingredientibus,”* edited by B. Geyer, p. 483) prefigured the pattern that was to be followed by the modernists. He pointed out that if “alone” is taken to be part of the subject, the statement is about a man who happens to be by himself, while if “it is attached to *the predication* it denies the capacity for laughter to all non-men, as if to say: ‘a man is capable of laughter in such a way that nothing else is capable of laughter.’”

When the investigation of syncategorematic words appeared as a separate inquiry in the treatises on syncategoremata by William of Sherwood and Peter of Spain (first half of the thirteenth century), the distinguishing characteristic of syncategorematic words was the fact that they had some effect on the relation between the categorematic words—that is, the predication or the “composition”—or on the relation between two predications or compositions. Thus Sherwood’s inventory of syncategoremata, most of which became standard, included the

verbs “begins” and “ceases” and the noun “nothing” as well as grammarians’ syncategoremata such as “every,” “both,” “except,” “alone,” “is,” “not,” “necessarily,” “if,” “unless,” “and,” and “or.” The standard syncategoremata, then, cannot be completely described as a selection of logical operators, although they plainly included such a selection. Nor was the investigation of them aimed primarily at uncovering their strictly formal properties. Many of the rules put forward in connection with one or another syncategorema were rules of inference—such as “When there are two distributions over one and the same part of a locution, the first immobilizes the second” (Sherwood)—but just as many were semantic rules—such as “The sign ‘every’ or ‘all’ requires that there be at least three appellata [for the term to which the sign is attached]” (Sherwood)—and there seems to have been no clear distinction drawn between the two sorts of rules.

The modernists’ treatises on syncategoremata presupposed the doctrine of the properties of terms, as is shown by the rules given just above, and much of their discussion of the function of such words is in terms of the various modifications of supposition produced within the scope of one or another syncategorema. (The problem of determining the scope of syncategoremata, especially in contexts including more than one, was particularly important in these investigations.) In this way the syntactic and semantic questions about syncategoremata were essentially interconnected. Sherwood at least among the older modernists was sometimes concerned to discuss the *signification* of syncategoremata—“every,” for example, was said by him to signify universality—but that seems to have been a feature of his unusual doctrine that in order to be significant a word had to signify some *form*. Most writers on syncategoremata took up Priscian’s really unjustified translation of the Greek *syncategoremata* as “consignificants” and used it as the basis for their view that “strictly speaking, a syncategorema signifies nothing, but when added to another word it makes that word signify something, or makes it supposit for something or some things in some definite way, or exercises some other function having to do with a categorema” (William of Ockham, *Summa Logicae*, I, 4; cf. the remarks of John of Salisbury in *Metalogicon*, Book I, Ch. 16).

The initial impetus to the study of syncategoremata came from the twelfth-century interest in fallacies, and the investigation continued to be associated with fallacies or with sophismata throughout its development. Observations about syncategoremata were only incidental in the twelfth-century treatises on fallacies, but the novel

emphasis of the *logica moderna* on the syncategoremata themselves is evident in the development of a new sort of treatise—"On Exponibles"—in the first half of the thirteenth century. "An exponible proposition is a proposition having an obscure sense that stands in need of exposition because of some syncategorema located in it explicitly or implicitly or in some word" (*Tractatus Exponibilium*, doubtfully ascribed to Peter of Spain, in *The Summulae Logicales of Peter of Spain*, edited by J. P. Mullally, p. 104). The exponibles did not involve fallacious arguments nor were they, strictly speaking, ambiguous. They were simply subjects for analysis, an analysis that was to explicate the force of some syncategorema in some particular context. For example, "'Man *inasmuch as* [*inquantum*] he is rational is not capable of braying'—that is, [1] no man is capable of braying and [2] every man is rational and [3] no rational entity is capable of braying and [4] because an entity is rational it is not capable of braying" (p. 115).

SOPHISMATA. The sophismata that played an increasingly important role in investigations of syncategoremata from the thirteenth through the fifteenth centuries may be characterized as falling somewhere between fallacies of ambiguity and exponible propositions. In the independent treatises on syncategoremata prevalent in the thirteenth century, the sophismata served as the illustrations of the principles uncovered in the investigation and characteristically took the form of an assertion (the sophisma proper) followed by a proof, a counterargument, and an adjudication of the apparent paradox by an appeal to the principles. For example, "Suppose that exactly one individual of each species of animal is running. Then [*a*] every animal is running. (Proof: a man is running; a lion ... ; a goat ... ; and so on with respect to the individuals; therefore every animal is running.) But [*b*] every man is an animal; therefore every man is running. [Solution:] [*a*] is ambiguous since [because of 'every'] the word 'animal' can distribute for the remote parts (or the individuals belonging to genera)—in which case it is false, since it is then distributed for all its individuals—or for the genera of the individuals (or for the proximate parts)—in which case the minor [*b*] is plainly not accepted" (William of Sherwood, *Syncategoremata*, edited by J. R. O'Donnell, in *Medieval Studies*, Vol. III, p. 49).

The continuity of the development of the *logica moderna* was enhanced by the fact that from the twelfth century through the fifteenth century the same sophismata were treated from varying points of view, but at the same time the number and intricacy of the sophismata

were constantly increasing. As a result the modernists of the fourteenth century frequently produced treatises titled *Sophismata* in which large numbers of them were grouped according to the syncategoremata at issue in them, and the investigations that had begun in separate treatises on syncategoremata were pursued in the *Sophismata* and *Exponibilia* of the late Middle Ages.

SPECULATIVE GRAMMAR

The notion that grammar and philosophy were intimately related was one of the most pervasive of the assumptions that determined the character of medieval thought. It is probably to be explained by the facts that grammar was one of the very few inquiries to survive antiquity intact and that the only ancient philosophy available during the early Middle Ages was Aristotle's *Categories* and *De Interpretatione*, works of a decidedly grammatical cast. The usual view of the connection between the two subjects was the one expressed most memorably by John of Salisbury—"Grammar is the cradle of all philosophy" (*Metalogicon*, Book I, Ch. 13)—and the *logica moderna*, by far the most impressive medieval contribution to semantics, is a clear example of the influence of grammar on philosophy. The influence ran the other way, however, in the development of "speculative grammar" (*grammatica speculativa*), or the doctrine of the "modes of signifying" (*modi significandi*), a movement that began somewhat later and subsided somewhat earlier than the *logica moderna*. Although there were some connections between the two movements—for instance, Roger Bacon (1214/1220–1292), one of the first of the speculative grammarians, or "modists," also contributed to the *logica moderna*—they tended to be mutually independent and to some extent theoretically opposed developments in the history of semantics.

The most important single factor in the rise of speculative grammar in the early thirteenth century was the enthusiasm for the notion of a *science*, then being rediscovered in the *Posterior Analytics* of Aristotle and in his Arabic commentators. For a time it was the aim of every study to achieve the status of an Aristotelian science, a body of necessary knowledge deductively demonstrated, and two facts seemed to stand in the way of certifying grammar as a science. For one thing, as it had been presented by Priscian and Donatus, grammar was simply a set of observations about correct constructions without any attempt at explanation of the correctness; but only knowledge "by causes" qualified as scientific. For another, even Peter Helias (fl. 1150), who in his com-

mentaries on Priscian had been the first medieval to attempt explanations of grammatical facts, had maintained that there were as many grammars as there were languages; but a unified subject matter was a prerequisite of a science.

Thus a science of grammar was not to be found in the grammatical authorities, and it seemed one never would be found as long as grammar was conceived of as something to be discerned only in the investigation of actual languages. Robert Kilwardby (d. 1279) set the stage for speculative grammar when he argued that “since a science remains the same for all men and its subject matter remains the same, the subject matter of grammar must remain the same for all men. But grammatically ordered speech or articulate utterance that can be put into a grammatical pattern is *not* the same for all men, and for that reason it will not be the subject matter of grammar [as a science]” (Commentary on Book I of Priscian’s *Ars Minor*). No science of languages was possible, but grammar might become the science of language, the *scientia sermocinalis*, if the variable external trappings were ignored and one concentrated on the conceptual underpinnings—which, as Aristotle had pointed out, *were* the same for all men. Thus Roger Bacon was led to proclaim that “with respect to its *substance* grammar is one and the same in all languages, although it does vary *accidentally*” (*Grammatica Graeca*, edited by E. Charles, p. 278), and this became the often repeated fundamental assumption of the speculative grammarians.

As it developed, speculative grammar took the form of an attempt to provide an Aristotelian ontology of language, finding analogues in the various parts of speech for matter, form, substance, process, and so on. As Siger of Courtrai (d. 1341) put it, “grammar is the *scientia sermocinalis*, which considers discourse and its properties [*passiones*] in general for the purpose of expressing principally concepts of the mind by means of interconnected discourse” (*Summa Modorum Significandi*, edited by G. Wallerand, p. 93). Siger then cited Avicenna for the Aristotelian doctrine that concepts are the same for all men because they are the result of experiencing extramental entities, which are the same for all men. Thus, the ontology that applies to the extramental entities must apply as well to the concepts derivative from them (if they adequately copy the extramental entities) and, in turn, to the discourse employed to express those concepts (if it is to be adequate for that purpose). “Therefore *modes of being*, or properties of things ..., precede a *mode of understanding* as a cause precedes an effect” (ibid.). In the same way a mode of designating

(*modus signandi*) follows a mode of understanding, “since a thing is understood and also conceived of before it is designated by means of an *utterance* [*vox*], for utterances are signs of passions, as is said in *De Interpretatione*, Ch. 1” (p. 94). When the understanding assigns a given concept to an utterance, the merely physical utterance becomes a word (*dictio*).

Up to that point the semantic theory underlying speculative grammar might fairly be described as a technical restatement of Aristotle. It was only with the introduction of its “modes of signifying” that the theory acquired its novelty and notoriety. (It was repeatedly attacked and ridiculed by logicians and grammarians of the late Middle Ages and even more strongly assailed by the Renaissance humanists.) As an utterance becomes a word by means of a mode of designating, so a word becomes one or another part of speech by means of a mode of signifying. The modes of signifying, however, are not modes of the utterance of the word but are “certain concepts of the understanding itself” (ibid.). The kind of concept in question seems to be one that links the word to some Aristotelian mode of being. Thus, the kind of concept involved in the mode of designating is the kind that supplies a *significatum* for the utterance “horse,” transforming it from a mere sound into a word, while the mode of signifying consists in the recognition that it is substance that is signified by the word *horse*. And when the understanding adds to that general mode of signifying—substance—the specific mode of signifying—quality—then *horse* has been transformed in turn from a mere word to a substantive and from a mere substantive to a noun (pp. 94–95). Along these same lines, the utterance *horse* will eventually be accounted for as a common concrete noun, and similar patterns of modes of signifying are invoked in order to account for the other parts of speech.

Aristotelian ontology was employed by the speculative grammarians not only as the link between grammatical forms and modes of extralinguistic being but also as a picture of intralinguistic relations. Thus, verbs stood at the pinnacle of the linguistic microcosm because just as the other animals are submissive to man, so the inflections of the other parts of speech in a sentence are ultimately submissive to the verb. The infinitive of a verb, however, was analogous to primary matter in substances. And just as the organisms capable of fewest adaptations are ranked lowest in the kingdom of nature, so the indeclinables, the syncategoremata, are the most inferior parts of speech (pp. [52]–[54]).

THE RENAISSANCE AND ENLIGHTENMENT

SEMANTICS, LOGIC, AND EPISTEMOLOGY

As the Middle Ages gave way to the Renaissance in the late fifteenth century, logic (on which semantics had been centered) first lost its medieval attainments and then subsided into inactivity until the middle of the nineteenth century. What little there was in the way of logical inquiry from about 1450 to about 1850 was carried on under the view of logic as the art (or science) of reason, the idea of *scientia sermocinalis* having been ridiculed into oblivion by the Renaissance humanists. Aside from the work of late Scholastics, such as the *Ars Logica* of John of St. Thomas (1589–1644), and an occasional deliberate attempt at revival, such as the *Logica Fundamentis Suis a Quibus Hactenus Collapsa Fuerat Restituta* (1662) of Arnold Geulincx (1624–1669), there were no further developments of the logicosemantic theories of the *logica moderna*.

Philosophers retained their interest in semantics, however, after losing interest in and even all knowledge of the kind of logic with which it had been associated. Epistemology dominated the philosophy of the Renaissance and the Enlightenment (for present purposes, roughly 1500–1800) as logic had dominated medieval philosophy, and the development of semantics during this period centered on epistemology. As a consequence, much of the development took place in the context of discussions of nonlinguistic signs, such as representative ideas, and will not be directly considered here.

Perhaps partly because logic had lost its identity as an inquiry into language, the interest of philosophers in language was more intense and diversified during this period (and especially in the eighteenth century) than at any earlier time. Some of this interest was manifested in widespread speculation about the origin of language and in projects for a universal language or a “real characteristic.” Although works on these subjects are typical of the period and often contain material of value for the history of semantics, they can be considered here only as they bear directly on a theory of meaning or philosophy of language selected for discussion.

BACON

Francis Bacon (1561–1626) produced comparatively little that can be described as philosophy of language, but the occasional novel insights and the programmatic charac-

ter of what he did produce helped to give it a considerable influence over philosophy of language in the Enlightenment. Almost everything of his that is relevant to the history of semantics is to be found in the “Art of Elocution or Tradition” (in the *Advancement of Learning* and the *De Augmentis Scientiarum*) and the doctrine of the “Idols of the Market Place” (in the *Novum Organum* and the *De Augmentis Scientiarum*).

The first of these is plainly Bacon’s revised version of the medieval *trivium*—grammar, logic, rhetoric—although he nowhere says so. In the later Middle Ages these subjects had sometimes been designated the *artes sermocinales*, and in the *De Augmentis Scientiarum* Bacon said that the subject matter of the *ars tradendi* was *sermo*. This inquiry into “tradition”—that is, discourse or communication—had three branches, concerning “the organ,” “the method,” and “the illustration” of tradition; and most of the work of the three branches was explicitly associated with grammar, logic, and rhetoric, respectively. For present purposes the first of these three branches is much more important than the other two.

In his scheme of “Human Philosophy” the Art of Tradition occurred as “the fourth kind of Rational Knowledge” (Spedding, Ellis, and Heath, eds., 3.383–4), because reason was “as it were the soul of discourse,” according to Bacon. “Nevertheless, in treating of them reason and discourse ought to be separated, no less than soul and body” (1.651). He began his separate treatment of discourse by identifying speech and writing as the most familiar organs of discourse and stressing their connection with reason by citing with approval the traditional version of Aristotle’s doctrine: “Words are the images of cogitations, and letters are the images of words” (3.399; but cf. 3.284, 3.85–86). But his interest in less familiar organs of discourse prompted him to frame a set of general conditions for an organ of discourse: “Whatever can be broken down into differences sufficiently numerous for explicating the variety of notions (provided those differences are perceptible to sense) can become a vehicle of cogitations from one man to another” (1.651; cf. 3.399). An organ of discourse can be used to *communicate* nothing but notions, but it will contain elements that *express* not only notions but also things.

In the most familiar arrangement of organs of discourse, words (by which Bacon meant only articulate sounds [2.411–412]) are expressed by letters—that is, phonograms. Letters, in turn, may be expressed by ciphers—that is, cryptograms—and both letters and ciphers may be designated “nominal characters.” But he recognized another kind of “notes of things, which signify

things *without* the aid or intervention of words,” either “on the basis of congruity” or “arbitrarily.” As examples of the former sort he cited hieroglyphics and gestures, gestures being “transitory hieroglyphics,” the “words” for which hieroglyphics may be the “letters,” and he classified them together as “emblems”—that is, sensible images to which intellectual conceptions could be reduced by analogy (1.652–653; 649). As examples of the latter sort he cited “real characters” such as Chinese ideograms, which “have nothing emblematic in them, but are simply surds, no less than the elements of letters themselves; ... there ought to be as many of them as there are radical words” (1.653).

Despite that disadvantage, real characters could and, Bacon thought, did function as an organ of discourse beyond the limits of a single natural language just because they signified “things and notions” without the intervention of words (1.652). Although he was convinced that there were no more convenient organs of discourse than words and letters, Bacon listed the study of the notes of things among his desiderata (1.653). Acting on this suggestion, the Royal Society commissioned some of its members to look into the project of a universal real character, the eventual result being John Wilkins’s *Essay towards a Real Character and a Philosophical Language* (1668), one of many such attempts during this period.

As another part of the inquiry into organs of discourse Bacon proposed a “philosophical grammar,” and this desideratum likewise had an extensive but un-Baconian influence. Some of what he had to say about philosophical grammar was reminiscent of the medieval speculative grammar—for instance, it was to be “a kind of grammar that would carefully inquire not into the analogy of words to one another, but into the analogy between words and things or words and reason” (1.654)—and this is what seems to have caught the imagination of his many successors in the Enlightenment who produced works in philosophical or “universal” grammar. What Bacon really had in mind was probably something more nearly like the comparative philology characteristic of the nineteenth century: “But the noblest kind of grammar would, I think, result if someone well taught in many languages, learned as well as vulgar, would treat of the various properties of *languages*, showing in what respects each excels and in what respects it is deficient” (ibid.; cf. 3.230, 3.401). He did, however, go on to suggest that one might combine all the best properties uncovered in that analysis into “a very finely formed image and remarkable model of speech itself for expressing the mind’s meanings aright” (1.654).

In his sketch of a philosophical grammar Bacon emphatically disapproved of what he believed Plato had been attempting in the *Cratylus*, an inquiry into “the imposition and original etymology of names” (ibid.; cf. 3.531), but his own concern in the doctrine of the “Idols of the Market Place” closely parallels Plato’s real concern in the *Cratylus*, that is, distinguishing between correct and incorrect names. “The idols imposed on the understanding through words are of two kinds. Either they are names of things that are not (for just as there are things that lack a name because they have not been observed, so there are names that lack things, resulting from a fantastic supposition); or they are names of things that are, but confused, ill-defined, and rashly and irregularly abstracted from the things” (1.171). As an example of the first he gave “prime mover”; his example of the second kind was “humid,” which, as his discussion of it shows, is less objectionable on these grounds now than it was in seventeenth-century English.

HOBBS

Thomas Hobbes (1588–1679) conceived of his systematic philosophy as beginning with an investigation into language and produced different versions of the investigation in *Human Nature* (1650), Chapters 5 and 13; *Leviathan* (1651), Chapters 4–7; and *Elementa Philosophiae Sectio Prima: De Corpore* (1655; English 1656), Part I, “Computatio Sive Logica.” (The latest of those versions is also in most respects the fullest and is used as the basis of the following account.)

Philosophy, Hobbes observed, depends on ratiocination, or “computation” (Molesworth edition, 1.3). In reasoning regarding particular things “we add and subtract in our silent thoughts, without the use of words” (ibid.; see 3.32); but in most instances, and certainly in philosophizing, “men owe all their true ratiocination to the right understanding of *speech*” (1.36), such ratiocination being “nothing but reckoning, that is adding and subtracting, of the consequences of *general names*” (3.30). In the second chapter of his *Logic*, devoted specifically to “names,” Hobbes produced a novel combination of several elements in the Aristotelian-Scholastic account of the semantics of names. Ratiocination of every kind depends on memory, and the intelligent use of memory requires what Hobbes called “*marks*, namely, sensible things taken at pleasure, that, by the sense of them, such thoughts may be recalled to our mind as are like those thoughts for which we took them” (1.14).

It is possible, Hobbes thought, for a man to “spend all his time partly in reasoning and partly in inventing

marks for the help of his memory, and advancing himself in learning”—that is, to devise and profitably use a private language—but if science and philosophy are to develop, there must be “certain *signs* by which what one man finds out may be manifested and made known to others” (1.14). Signs that do “signify the cogitations and motions of our mind” are “*words* so and so connected,” or what Hobbes called “*speech*, of which every part is a *name*” (1.15). The use of names as marks, he held, was logically prior to their use as signs, since “names, though standing singly by themselves, are marks ...; but they cannot be signs otherwise than by being disposed and ordered in speech” (1.15). He recognized the syntactic disposition of names in speech as necessary but not sufficient for “declaring our conceptions to others.” Speech cannot “perform that office alone without the help of many circumstances,” such as “time, place, countenance, gesture, the counsel of the speaker” (2.274). We must “consider the drift, and occasion, and contexture of the speech, as well as the words themselves” (4.23).

When names are ordered in speech so as to be signs rather than marks, “it is manifest they are *not* signs of the things themselves” but signs only of our conceptions (1.17). Hobbes seems to have been following Aristotle’s lead here, but more faithfully than most, since he went on to say, “That the sound of this word ‘stone’ should be the sign of a stone, cannot be understood in any sense but this, that he that hears it collects that he that pronounces it thinks of a stone” (1.17). Thus, even though indirectly and only in virtue of signifying that the speaker is thinking of a stone, the name “stone” ordered in speech *is* a sign of a stone. At any event, Hobbes nowhere suggested that “stone” occurring in speech was a *name* of some mental entity. On the contrary, in going on to show that “it is not at all necessary that every name should be a name of some thing,” Hobbes began by pointing out that “‘man,’ ‘tree,’ ‘stone’ are *names* of things themselves” (1.17), though they may be used as *signs* of our conceptions of men, trees, and stones and as *names* of “fictions and phantasms of things,” such as images in dreams. “Moreover, that which neither is, nor has been, nor ever shall, or ever can be, has a name, namely, ‘that which neither is, nor has been,’ &c.; or more briefly this, ‘impossible’” (1.17). For “a name is not taken in philosophy, as in grammar, for one single word, but for any number of words put together to signify one thing” (1.23), Hobbes having decided “to apply the word ‘thing’ to whatsoever we name; as if it were all one whether that thing be truly existent, or be only feigned” (1.18).

Much of Hobbes’s investigation of names was presented in the form of discussions of traditional classifications of names. His treatment of them sometimes presents the half-understood remnants of complex medieval theories—for instance, his treatment of names of first and second intention (1.20–21)—but there are occasional interesting novelties as well. In his discussion of common and proper names he put forward his strict nominalism: “this word ‘universal’ is never the name of any thing existent in nature, nor of any idea or phantasm formed in the mind, but always the name of some word or name” (1.20); at another point he remarked that the univocal-equivocal distinction “belongs not so much to names as to those that use names” (1.23); and he based the distinction between simple and compound names not on appearances but on considerations of analyzability, so that in the context of a discussion of man “body” is a simple name while “man” is a “more compounded name,” being equivalent to “animated rational body” (1.23–24).

Hobbes encountered important difficulties in his discussion of names of “certain and determined” and of “uncertain and undetermined” signification (1.21–23), which is evidently a badly distorted remnant of supposition theory. In the course of that discussion Hobbes was led to claim, for example, that *particular* names—such as “some man”—“are of *uncertain* signification, because the hearer knows not what thing it is the speaker would have him conceive” (1.22), as if the “uncertainty” in, say, “some man will marry my daughter” were the sort that could always be resolved by asking the speaker “*which* man?” Even worse confusion resulted from his attempt to show that such quantifiers as “every” and “some” were unnecessary for purposes of reasoning. Such words, he maintained, “which denote universality and particularity, are not names; so that ‘every man’ and ‘that man which the hearer conceives in his mind’ are all one; and ‘some man’ and ‘that man which the speaker thought of’ signify the same. From whence it is evident, that the use of signs of this kind, is not for a man’s ... getting of knowledge by his own private meditation (for every man has his own thoughts sufficiently determined without such helps as these) but ... for the teaching and signifying our conceptions to others” (1.22).

In his treatment of propositions Hobbes sometimes spoke as if only such propositions as “Cicero is Tully” were true—for instance, “that proposition only is true in which are copulated two names of one and the same thing” (1.57)—but usually his description of a true proposition was more moderately and more accurately expressed along such lines as these: “A *true* proposition is

that, whose predicate contains, or comprehends its subject, or whose predicate is a name of every thing, of which the subject is a name" (1.35; cf. 4.23–24). He produced a detailed analysis of falsity as reducible to combinations of names of different sorts of entities (1.57–62). His truth theory was, however, quite radical in other respects. The "first truths," he claimed, "were arbitrarily made by those that first of all imposed names upon things, or received them from the imposition of others. For it is true [for example] that *man is a living creature*, but it is for this reason, that it pleased men to impose both those names on the same thing" (1.36). This suggests an identification of the proposition with a particular sequence of words, but Hobbes elsewhere gave the impression of having been on the point of drawing a clear distinction between propositions and the vehicles of their expression—for instance, "every proposition may be, and uses to be, pronounced and written in many forms.... And therefore, whensoever they [students of philosophy] meet with any obscure proposition, they ought to reduce it to its most simple and categorical form" (1.39).

Hobbes rejected the analysis of contingent categorical propositions into their corresponding hypothetical forms, pointing out that while this analysis was allowable for *necessary* categoricals, "in contingent propositions, though this be true, 'every crow is black,' yet this, 'if any thing be a crow, the same is black' [i.e., '(x)(Cx ⊃ Bx)'], is false" (ibid.). In several places Hobbes discussed the various uses of speech—for example, *Human Nature*, Chapter 13—and at one point argued against the notion that a promise simply by its form of words creates an obligation (2.18–20).

THE PORT-ROYAL LOGIC

René Descartes (1596–1650) had very little to say about language, but Antoine Arnauld (1612–1694) took an avowedly Cartesian approach to semantic questions in the *Port-Royal Grammar* (*Grammaire générale et raisonnée*, with Claude Lancelot, 1660) and the *Port-Royal Logic* (*Logique ou l'art de penser*, with Nicole, 1662). The latter book had a tremendous influence; it marks, better than any other, the abandonment of the medieval doctrine of an essential connection between logic and semantics. Disdain for medieval theories was emphatically expressed in it—"No one, thank God, is interested in ... second intentions" (*Premier Discours*)—but at several points the theories were still employed (for instance, in 1.2 and 2.10) and elsewhere in the book they were supplanted by innovations that sometimes obscured what had been clear in the *logica moderna*.

In words reminiscent of Hobbes's on this point, Arnauld remarked that if logic considered only an individual's reflections on his ideas, the investigation of language would form no part of it. But we must use "exterior signs" for communication, "and since this custom is so strong that even when we think by ourselves things are presented to our mind only together with the words with which we are accustomed to adorn them in speaking to others, it is necessary in logic to consider the ideas joined to words and the words joined to ideas" (introduction; cf. Descartes, *Principles*, Part I, Principle 74). Arnauld of course argued (1.1) against Hobbes's anti-Cartesian suggestion that reasoning might be "nothing more than the uniting and stringing together of names or designations by the word 'is,'" so that all we could ever conclude is "whether or not there is a convention (arbitrarily made about their meanings) according to which we join these names together" (*Objections to Descartes's Meditations*, 3.4).

Signs and signification were frequently discussed in the *Port-Royal Logic*, sometimes with interesting results; the most fundamental questions were, however, treated with the kind of inattention to detail that came to characterize most of the many semantic theories of the Enlightenment. "The sign," said Arnauld, "comprises two ideas—one of the thing that represents, the other of the thing represented—and its nature consists in exciting the second by means of the first" (1.4). In the case of words, the "thing represented" was identified as a "thought" or an "idea." Even proper names were defined as those "that serve to mark ... the ideas that represent only one single thing," and "general words" were said to be those "that are joined to universal and general ideas" (1.6). The doctrine is so far consistent and recognizably Cartesian, even if crude. But it is complicated, no doubt inadvertently, by many suggestions of a different sort of signification for words. Thus, on a single page Arnauld began by calling words "sounds that are intended to signify *ideas*," went on to speak of "things and modes" as "the *objects* of our thoughts," and ended by defining names as "the words intended to signify both *things and modes*" (2.1); and he nowhere provided an account that might justify this extended use of "signify." He may have been assuming a transitivity of signification—words signifying ideas representing things—but John Locke was the first to attempt to spell out such a theory.

Arnauld warned against the "great equivocation in the word 'arbitrary' when we say that the signification of words is arbitrary," pointing out that while "it is purely arbitrary to join one idea to one sound rather than to

another,” nevertheless the ideas, “at least those that are clear and distinct,” are not arbitrary. The result of correct reasoning is “a solid, effective judgment regarding the nature of things based on the consideration of the ideas of them a man has in mind, which ideas it has pleased men to mark by means of certain names” (1.1). But, on the other hand, one of his reasons for rejecting Aristotle’s categories was that they were “arbitrary names that form no clear and distinct idea in the mind” (1.3).

Arnauld also explicitly rejected Aristotle’s definition of a verb, putting in its place one that not only captured the essence that Aristotle missed but was also much simpler: “a word that signifies affirmation” (2.2). Evidently he did not mean that it signified the idea of affirmation (as would the noun “affirmation”), but he did not work out the definition in a way that tied it to the rest of his signification theory.

Like so many other philosophers of the period, Arnauld believed that “the best means of avoiding the confusion of words to be found in ordinary languages is to make a new language and new words that would be attached only to the ideas we want them to represent.” He differed from most, however, in suggesting that this be accomplished simply by a conscientious, systematic use of precise nominal definitions attached to already extant vocables of ordinary languages (1.12).

One of the more interesting notions in Arnauld’s doctrine of signification was introduced in his observation that “it often happens that besides the principal idea (which is regarded as its *proper* signification) a word excites several other ideas that may be called *accessory*.” Sometimes the accessory ideas are attached to the words “as the result of common usage,” as in “you lied,” the *proper* signification of which is the idea that you knew the contrary of what you said, the ideas of contempt and outrage being *accessory* (1.14). In some respects this is reminiscent of Augustine’s doctrine in *Principia Dialecticae*, especially when Arnauld uses it to argue (against Cicero) that certain words may, in virtue of their accessory ideas, be described as unchaste (1.14). Accessory ideas may also be attached for the purpose of a single use of a word, and on that basis Arnauld attempted an explanation of the varying signification of the demonstrative pronoun “this,” here as elsewhere in the book applying his semantic doctrines to the elucidation of the formula of transubstantiation—“this is my body” (1.15).

Arnauld’s notion of accessory ideas might have been (but was not) used to advantage in his discussion of problems of identity of reference, where he argued that when the mind frames the proposition “that Rome, which was

of brick before the time of Augustus, was of marble when he died, the word ‘Rome,’ which appears as only one subject, nevertheless marks two subjects that are really distinct but reunited under a confused idea of Rome that prevents the mind from perceiving the distinction of subjects” (2.12). The suggestion is that the proposition should be rejected by anyone having a clear and distinct idea of Rome, which is preposterous. Even if the *proper* signification of “Rome” was taken to be only the idea of buildings, surely such *accessory* ideas as location, population, and institutions could have been invoked to warrant the continuing use of the single proper name.

Like Hobbes, Arnauld recognized complex terms expressed in a single word, but instead of Hobbes’s criterion of analyzability Arnauld employed the notion of accessory ideas attaching to the word under certain circumstances. Thus, the term *king*, which is simple “*in expression*,” was “a term complex *in sense*” when uttered in seventeenth-century France, “because in pronouncing the word ‘King’ we not only have in mind the general idea corresponding to that word; we also mentally join to it the idea of Louis XIV, who is now King of France. There is an infinity of terms in ordinary human discourse that are complex in this respect” (1.8).

Arnauld’s analysis of the semantics of sentences clearly illustrates the importance of the loss of supposition theory. In one badly confused but typical passage he claimed that “when one says that men are animals, the word ‘animal’ no longer signifies all animals, but only the animals that are men” (2.17). Not only does this transform predication into identity, it also violates his own doctrine of signification. Again, in discussing “some man is just” Arnauld maintained that “just” there “signifies only the justice that is in some man,” the result being that “some man is identified with some just [thing]” (2.18).

A complete chapter of the *Port-Royal Logic* is devoted to the discussion of propositions such as “this is Alexander” (pointing to his portrait), which he described as “expressions in which one uses the name of the thing to mark the sign,” seldom if ever causing any difficulty in actual use, and propositions such as Joseph’s explanation of Pharaoh’s dream—“the seven full sheaves are seven full years of plenty”—“expressions in which, the sign being marked by its own name or by a pronoun, one affirms of it the signified thing.” One result of this novel approach to metaphor is his formulation of a rule governing the appropriateness of the second sort of proposition: “the mind of those to whom one speaks must already regard the sign as a sign and be concerned to know of what it is a sign” (2.14).

“COMPREHENSION” AND “EXTENSION.” Certainly the most influential semantic doctrine of the *Port-Royal Logic* was Arnauld’s introduction of a distinction between the “comprehension” and the “extension” of a term. (In the nineteenth century Sir William Hamilton renamed the former “intension.”) The principle of such a distinction had been employed in the medieval distinction between simple and personal supposition, and even the distinction itself had occasionally been anticipated in one form or another (for instance, by Cajetan), but Arnauld’s introduction of it seems to have been original and certainly was the first instance of a systematic use of it.

It is difficult, however, to say exactly what Arnauld intended by the distinction, for its exposition is obscured by his generally confused account of signification. He first advanced the distinction as one pertaining to “universal ideas” (or terms). “I call the *comprehension* of the idea the attributes it comprises in itself that cannot be removed from it without destroying it, as the comprehension of the idea of the triangle comprises extension, figure, three lines, three angles, the equality of those three angles to two right angles, etc. I call the *extension* of the idea the subjects with which that idea agrees, ... as the idea of triangle is extended to all the various species of triangle.” And Arnauld went on to say that the idea could be restricted in its extension by “applying it to only some of the subjects with which it agrees, without thereby destroying it,” for example, by attaching to it “an indistinct and indeterminate idea of a part, as when I say ‘some triangle’” (1.6). If, however, the extension consists of species and not of the individuals, which is what Arnauld maintained, then such a device for restricting extension is always to be read as “some (species of) triangle,” which produces an absurdity. Because of his theory of signification there would be theoretical difficulties for Arnauld in simply identifying the term’s extension with the individuals in question, but for the most part he seems to have had that identification in mind rather than the one he laid down.

Individual terms, too, were said to have comprehension and extension. In the phrase “Julius Caesar, the greatest commander the world has ever seen,” the comprehension of that individual term is “explicated” in one of countless possible ways. But the extension of an individual term cannot be restricted, Arnauld maintained, and thus every singular proposition is universal (1.8, 2.3).

LOCKE

In the third book of his *Essay Human Understanding* (1690) John Locke (1632–1704) produced the first mod-

ern treatise devoted specifically to philosophy of language. No work had a greater influence over the development of semantics during the Enlightenment than did Book III of this work, “Of Words”; yet its semantic theories were neither novel in principle nor clearly and thoroughly developed. To go no further back, many of its principles had been anticipated in Kenelm Digby’s *Two Treatises* (1664), in Richard Burthogge’s *Organum Vetus et Novum* (1678), and in Hobbes’s works. Of course Locke’s “Of Words” acquired importance simply by being a part of the enormously influential *Essay*, but the source of its special influence lay in the fact that Locke had expressly connected semantic inquiry with theory of knowledge. He had set out to investigate “our knowledge,” and along the way he found himself unexpectedly compelled to investigate “the force and manner of signification” of words (3.9.21), having discovered that “there is so close a connexion between ideas and words ... that it is impossible to speak clearly and distinctly of our knowledge, which all consists in propositions, without considering, first, the nature, use, and signification of Language” (2.33.19). The new epistemological orientation of semantic inquiries, apparent even in the logic books of the period, was first explicitly established in Locke’s *Essay*.

Locke evidently thought of the material of Book III as serving two purposes in his philosophy. On the one hand, he characterized his new “way of ideas” as nothing more than “the old way of speaking intelligibly” (third letter to Stillingfleet), which he reduced to a few commonsensical maxims for the avoidance of “jargon,” very much in the spirit of Bacon’s treatment of the “Idols of the Market Place.” The semantic theory in Book III was developed in part as a support for these “remedies of the ... imperfections and abuses of words” (3.11), and Locke’s preoccupation with that practical aim may help to explain some of the imprecision and inconsistency in his theoretical statements. He did, however, clearly recognize a more strictly theoretical purpose in the semantic inquiries of Book III, one which he summarized in his description of the third branch of science—“*Σημειωτική, or the doctrine of signs*” (4.21.4), the consideration of ideas as the signs of things and of words as the signs of ideas.

Locke’s account of words as the signs of ideas shows little of the sensitivity to the complexities of language that had characterized the work of many of his predecessors, including Hobbes. Except for one very short, cryptic chapter on “particles” (by which he evidently meant syntagorematic words but perhaps also verbs), the seman-

tics of words in Book III is exclusively a semantics of “names”—names of “simple ideas,” of “mixed modes,” and of “natural substances”—with no suggestion that anything has been left out of consideration (3.4.1).

The development of his fundamental thesis regarding the signification of these names begins with his observing that “words being voluntary signs, they cannot be voluntary signs imposed by [a man] ... on things he knows not.” Now what a man knows is in his mind, but all that is in a man’s mind is his own ideas. Therefore, “words, in their primary or immediate signification, stand for nothing but *the ideas in the mind of him that uses them*” (3.2.2). This is not markedly different from the starting point of many earlier semantic theories, but Locke’s initially uncompromising development of it led to some extreme consequences. Men, he observed, “suppose their words to be marks of the ideas also of other men” or “to stand also for the reality of things.” Faithful to his fundamental thesis, Locke nevertheless insisted that “it is a perverting the use of words, and brings unavoidable obscurity and confusion into their signification, whenever we make them stand for anything but those ideas we have in our own minds” (3.2.4–5).

Thus, the basic semantic relation in Locke’s account of language is that of a word used by some speaker as a proper name for some idea in that speaker’s mind. It seems to follow from this doctrine that as long as one does use words in this (the only approved) way, one cannot misuse them; and Locke does sometimes suggest that in the early chapters of Book III (see, for instance, 3.2.3). Those chapters indeed present a classic formulation of what Wittgenstein was later to criticize as the notion of a “private language.”

Establishing words as proper names of ideas in the speaker’s mind fulfills the first of Locke’s two principal conditions “for the perfection of language” (3.1.3). The second was the devising of “general words,” which he thought men accomplished by using words “for signs of general ideas.” It was evident, Locke observed, that general words “do not signify barely one particular thing; for then they would not be general terms but proper names.” His account of the signification of general words is, however, severely damaged by the inclusion in those same passages of his declaration of a thoroughgoing nominalism: “things themselves ... are all of them particular in their existence, even those words and ideas which in their signification are general” (3.3.11–12).

Although many of his most careful theoretical statements ruled out any extension of the signification of a word beyond an idea in the speaker’s mind, Locke here

(and frequently in the later chapters of Book III) was apparently assuming that by virtue of signifying an idea, a word also (secondarily and indirectly, perhaps) signified whatever the idea signified. However, he never examined that assumption or even recognized it to be one. When he came to apply his theory to the discussion of various sorts of names, he often relaxed or ignored the strictures laid down in the general theory developed in the first three chapters. Thus, in his chapter on the “names of our ideas of substances” he found it convenient to say “By the word *gold* here, I must be understood to design [that is, designate] a particular piece of matter; v.g., the last guinea that was coined. For if it should stand here in its ordinary signification, for that complex idea which I or anyone else calls gold, i.e. for the nominal essence of gold, it would be jargon” (3.6.19).

When, on the other hand, Locke did apply his semantic theory strictly, he was likely to produce such surprising results as his doctrine that every generalization about a substance, such as “all gold is fixed,” means either “that fixedness is a part of the definition, i.e., part of the nominal essence the word gold stands for; and so this affirmation ‘all gold is fixed,’ contains nothing but the signification of the term gold. Or else it means, that fixedness, not being a part of the definition of the gold, is a property of the substance itself, in which case it is plain that the word gold stands in the place of a substance.... In which way of substitution it has so confused and uncertain a signification that, though this proposition—‘gold is fixed’—be in that sense an affirmation of something real, yet it is a truth will always fail us in its particular application [since we know only our idea of gold and not ‘the real essence’ of gold], and so is of no real use or certainty” (3.6.50; compare his interesting treatment of “trifling propositions” in 4.8).

Locke’s strictly subjectivist, nominalist theory of signification in the opening chapters of Book III, which gave him so much trouble in its application, may represent nothing more than his overzealous attempt to state precisely such characteristically commonsensical observations as can be found in his *Conduct of the Understanding*, Section 29, where he advised “those who would conduct their understanding right, not to take any term ... to stand for anything, till they have an *idea* of it. A word may be ... used as if it stood for some real being; but yet if he that reads cannot frame any distinct idea of that being, it is certain to him a mere empty sound without a meaning.”

(Locke’s influence is frequently discussed in the remainder of this entry. See, for instance, the sections on

Gottfried Wilhelm Leibniz, George Berkeley, and Étienne Bonnot de Condillac and on universal grammar.)

LEIBNIZ

Gottfried Wilhelm Leibniz (1646–1716) developed some of his views on language specifically as criticisms of Locke in his *Nouveaux Essais sur l'entendement* (finished after 1709; first published 1765). One example of this *ad hoc* development is his rejection of Locke's account of "general words" as no more than devices for avoiding the proliferation of proper names. Leibniz argued that they were necessary ingredients in the "essential constitution" of languages and went so far as to claim, in an exact reversal of Locke's position, that "it is certain that all *proper* or individual names were originally *appellative* or general" (3.1.3; see 3.3.5). Even in the *Nouveaux Essais*, however, most of Leibniz's views on language can be traced to considerations that lie at the center of his own philosophy.

UNIVERSAL CHARACTERISTIC. Perhaps the most important of the central considerations of Leibniz's philosophy is his lifelong preoccupation with the idea of a "universal characteristic," which cannot be examined here except as it bears directly on his philosophy of language. Leibniz's earlier doctrine of the characteristic (c. 1679) was "that a kind of alphabet of human thoughts can be worked out and that *everything can be discovered and judged by a comparison of the letters of this alphabet and an analysis of the words made from them*" (Gerhardt edition 7.185). Descartes, by contrast, had maintained that such a language (he never knew of Leibniz's scheme, of course) depended on the prior establishment of "the true philosophy" (letter to Marin Mersenne [1629], in Adam and Tannery edition 1.76).

Leibniz's initial response was that while the establishment of the characteristic "does depend on the true philosophy, it does not depend on its completion"; for as long as we have the true "alphabet of human thought" to begin with, we can complete the true philosophy simply by correctly manipulating the characteristic (Couturat edition, pp. 27–28). (The many artificial languages projected during the Enlightenment may be classified as "Cartesian" or "Leibnizian," depending on whether they were put forward solely as devices for recording and communicating knowledge or also as heuristic devices. It is the Leibnizian rather than the Cartesian projects that bear a significant resemblance in principle to the formalized languages for logic developed after the middle of the nineteenth century.) Writing some years later (1697) and in a context where the issue between his own and

Descartes's views was not explicit, Leibniz did nevertheless acknowledge that "genuinely real, philosophic characters must correspond to the analysis of thoughts. It is true that such characters would presuppose the true philosophy, and it is only now [when he believed himself to have discovered the principles of the true philosophy] that I should dare to undertake the construction of them" (Gerhardt edition 3.216).

By a "real" characteristic Leibniz meant a symbolism that was in some important respect naturally (rather than conventionally) associated with what it symbolized. Although a thoroughly real characteristic could be developed only in an artificial language, Leibniz observed that natural languages were in certain respects real characteristics. It was on the basis of that observation that he became the first major philosopher after Epicurus to suggest an appeal to ordinary language as a philosophical technique. His general attitude is expressed in the *Nouveaux Essais*: "I truly think that languages are the best mirror of the human mind and that an exact analysis of the signification of words would make known the operations of the understanding better than would anything else" (3.7.6). Part of what he meant by "exact analysis" closely resembled Plato's use of etymology in the *Cratylus*.

In his preface to a 1670 edition of Nizolius (in which he has a great deal to say about language) Leibniz argued that "the good grammarian and the philosopher too can, so to speak, deduce the use of a word from its origin by means of an unbroken sorites of metaphors" (Gerhardt edition 4.140). But he also viewed ordinary language in its unanalyzed state as having a special philosophic value: "Whatever cannot be explicated by means of popular terms (unless like many kinds of colors, odors, and tastes, it consists in immediate sensation) is nothing, and should be kept away from philosophy as if by a kind of purifying incantation" (4.143). Not every ordinary language was equally valuable as a touchstone for philosophy: "No language in Europe is better suited than German for this certifying trial and examination of philosophical doctrines by means of a living language, for German is richest and most nearly complete in real characters [*in realibus*], to the envy of all other languages.... On the other hand, the German language is easily the least well suited for expressing fabrications [*commentitia*]" (4.144; cf. Duclos edition 6.2.10 ff.). Leibniz's praise of German for its high proportion of real characters was very likely based simply on the fact that it contains words of Germanic origin where English and the Romance languages are likely to have words of Greek and Roman origin—for instance,

Unabhängigkeit and “independence”—a feature of the German language which no doubt does provide its native speakers with comparatively easy access to many abstract notions.

Leibniz also recognized a more pervasive kind of “realness” in natural languages that might be called *syntactic*, in contrast with the historically more familiar kind just discussed. It constituted the essential ingredient in his doctrine of “expression” and thus formed part of his metaphysics (monads *express* the universe) as well as of his philosophy of language. In *What Is an Idea?* (1678) he offered this account:

That is said to *express* a given thing in which there are relations [*habitudines*] that correspond to the relations belonging to the thing expressed. But these expressions are of different kinds—e.g., the model of a machine expresses the machine itself; the projective delineation of a thing in a plane expresses the solid; discourse expresses thoughts and truths; characters express numbers; an algebraic equation expresses the circle (or some other figure)—and what is common to these expressions is the fact that we can pass from the mere consideration of the expressed relations to a knowledge of the corresponding properties of the thing being expressed.

Leibniz drew the conclusion that “it is clearly not necessary that that which expresses be similar to that which is expressed as long as a certain analogy of [internal] relations is preserved” (Gerhardt edition 7.263–264). What he was proposing, however, was clearly a novel approach to resemblance as a basis for semantic relations, suggesting for the first time that in complex signs the “realness” of the symbolism may consist in the resemblance between the *schemata* of the expression and of what is expressed rather than in a resemblance between the *elements* of those two schemata. This was brought out most clearly in his *Dialogue* (1677)—for example, in the observation that “even if the *characters* are arbitrary, still *the use and interconnection* of them has something that is not arbitrary—viz. a certain proportion between the characters and the things, and the relations among different characters expressing the same things. This proportion or relation is the foundation of truth” (7.192).

In describing this schematic resemblance as the foundation of truth, Leibniz stated the principal thesis in his novel doctrine of propositions as extralinguistic, extramental schemata. Although such a notion of propositions had been hinted at by Hobbes, Leibniz was evi-

dently the first to make it explicit; and, as it happened, he developed his doctrine in conscious opposition to Hobbes’s view of truth as dependent on words and hence arbitrary. It had been standard philosophical usage from the beginning of the Middle Ages to use the word *proposition* for whatever was either true or false, and the principal refinement of this usage before Leibniz had been the medieval distinction of “mental” propositions from propositions spoken or written. Leibniz’s first objection against what he called Hobbes’s “super-nominalism” might be interpreted as going no further than that, as in his observation that “truths remain the same even if the notations vary” (*Preface to Nizolius* [1670], in Gerhardt edition 4.158). He subsequently recognized, however, that those “truths” could not be identified with true propositions that had been, were, or would be actually in someone’s mind—for instance, in the *Dialogue* of 1677: “A. ... Do you think that all propositions are thought? / B. I do not. / A. You see, therefore, that truth does belong to propositions or thoughts, but to *possible* [propositions or thoughts], so that this at least is certain, viz. that *if* anyone should think in this [or a contrary] way, his thought would be true [or false]” (7.190).

Once Leibniz had distinguished propositions from actual thoughts and from combinations of words, he was in a position to reject the traditional account of truth as “the conjunction or separation of signs according as the things themselves agree or disagree among themselves,” in which account “by ‘the conjunction or separation of signs’ one must understand what is otherwise called a proposition.” Leibniz’s attack on this tradition contrasted its technical terminology with ordinary usage in order to show that it concealed rather than resolved problems:

An epithet—e.g., “the wise man”—does not make a proposition, and yet it is a *conjunction* of two terms. Negation, moreover, is something different from *separation*, for saying “the man” and after an interval pronouncing “wise” is not to deny. Finally, *agreement* [or *disagreement*] is not, strictly speaking, what one expresses by means of a proposition; two eggs have agreement and two enemies have disagreement. The manner of agreeing [or disagreeing] at issue here is quite extraordinary [*toute particulière*]. Thus I think this definition completely fails to explicate the point at issue. (*Nouveaux Essais* 4.5.2)

And Leibniz went on from this criticism of the traditional doctrine of propositions to present once again his own

view of them as entities distinguishable both from words and from actual ideas (*Nouveaux Essais* 4.5.2).

“LEIBNIZ’S LAW.” Leibniz’s famous principle of substitutivity, known in recent literature as Leibniz’s Law, was frequently used as a starting point by twentieth-century writers on semantics. Leibniz employed the principle as part of the primitive basis of his logical calculus and put forward several versions of it in papers written from 1679 through the early 1690s. The various versions may be accurately synthesized as follows: Those entities are the same, one of which may be everywhere substituted for the other, preserving the truth(-value) (see 7.219; 7.228; 7.236).

Although Leibniz did not identify the entities in question and sometimes discussed the principle as if it applied, for example, to geometrical figures, the context generally makes it plain that its principal intended application was to terms in propositions actually expressed in some notation. His discussion of the principle in the papers in which he applied it took no account of contexts in which the principle does not apply, but at least one passage in his later writings shows that he had by then recognized that cases of what the medievals had called material supposition did not fall under the principle. “Indeed, one sometimes speaks of words *materially* without being able in that context [*cet endroit-là*] to substitute in place of a word its signification, or its relation to ideas or to things. This occurs not only when one speaks as a grammarian but also when one speaks as a lexicographer, in giving the explication of a name” (*Nouveaux Essais* 3.2.6). Recent criticism of Leibniz’s Law has often begun with the complaint that he failed to notice just such exceptions.

Berkeley. Locke had argued that a word was significant solely in virtue of standing for an idea in the mind of the user of the word. When George Berkeley (1685–1753) began philosophizing, he accepted that doctrine as axiomatic. In several early entries in his private *Philosophical Commentaries* (1707–1708) he presented it as part of the basis of his otherwise anti-Lockean position—for instance, “All significant words stand for Ideas” (Luce and Jessop edition 1.45; see 1.39, 1.43, 1.53). Even before ending the *Commentaries*, however, Berkeley had rejected Locke’s semantics too and had begun to replace it with a doctrine of great importance in the development of his own philosophy and in the history of semantics.

The actual turning point was apparently reached in his discovery that some words that should have been paradigm cases for Locke’s semantics had no precisely corre-

spondent ideas. “Qu: How can all words be said to stand for ideas? The word Blue stands for a Colour without any extension, or abstract from extension. But we have not an idea of Colour without extension; we cannot imagine Colour without extension” (1.62). In this passage Berkeley questioned for the first time not only Locke’s semantics but also (indirectly) his doctrine of abstract ideas. He very soon saw that the connection between the two was essential. Given Locke’s semantics, together with the facts that a general word was significant and that no concrete particular idea corresponded to it, one was forced to introduce a Lockean abstract idea simply in order to give a general word something to stand for. (As Berkeley pointed out [2.36], Locke had virtually admitted as much in the *Essay* [3.6.39].) Berkeley’s alternative account in the Introduction to *The Principles of Human Knowledge* (1710), Section 11, was that “a word becomes general by being made the sign, not of an abstract general idea but, of several particular ideas, any one of which it indifferently suggests to the mind” (2.31; see 2.127). Berkeley’s account thus involved abandoning Locke’s semantic principle that there be a single idea to serve as the name-bearer for each significant word.

In the history of semantics, however, as in the history of philosophy in general, Berkeley’s rejection of abstract ideas is more important than his alternative account of the signification of general words. The rejection was based not only on the well-known exposition of the internal inconsistency—as in *Principles*, Introduction, Section 13 (2.32–33)—but also on his many and varied attacks on their semantic foundation. Since Locke’s commitment to the view that each word had to stand for one idea in order to be significant was what had compelled him to introduce abstract ideas, Berkeley set out to show, by means of various sorts of counterinstances, “that words may be significant, although they do not stand for ideas. The contrary whereof having been presumed seems to have produced the doctrine of abstract ideas” (3.292–293; see 1.70).

He seems to have found at least four sorts of counterinstances, the first and most obvious consisting of words that stand for something other than ideas. Words such as “volition,” “I,” “person,” and the “particles” (or syncategorematic words) are significant in virtue of standing for “spirits” or their activities (the particles standing for “the operations of the mind”) (1.65, 1.80, 1.81; see 3.292). But in Berkeley’s immaterialism there were no entities other than spirits and ideas for which words could stand, and so there could be no other counterinstances consisting simply of words that stood for

nonideas. He was thus led to investigate the relation “stands for” more closely than its relation. In a move reminiscent of supposition theory he attacked Locke’s account of “understanding propositions by perceiving the agreement or disagreement of the ideas marked by their terms,” claiming that when he asserted of a particular dog “Melampus is an animal” he had not two ideas but “only one naked and bare idea, viz. that particular one to which I gave the name Melampus.” Nor does “animal” in that proposition “stand for any idea at all. All that I intend to signify being only this, that the particular thing I call Melampus has a right to be called by the name animal.” But it would not do, he pointed out, to say that “animal” here stood for the same idea as did “Melampus,” since that would make the proposition a tautology (2.136–137; cf. 1.69, 8).

The principal effect of this second sort of counterinstance was to raise some serious doubt regarding the nature of the relation “stands for,” and Berkeley’s remaining counterinstances took the almost unprecedented step of suggesting that that relation was not always an essential ingredient in significance. Words that might in certain occurrences be said to stand for ideas are very often used in reasoning and in ordinary conversation as uninterpreted (but interpretable) “counters.” A word used in that way does *not* in each of its occurrences stand for an idea in the mind of the user or, for that matter, raise a corresponding idea in the mind of the hearer or reader (2.37, 3.291–292, 8.25, 8.27).

Finally, a word sometimes occurs in a context such that one would miss rather than grasp its significance by taking it to stand for the idea to which it is customarily attached. “For example, when a Schoolman tells me *Aristotle hath said it*, all I conceive he means by it, is to dispose me to embrace his opinion with the deference and submission which custom has annexed to that name” (2.38). What is more, a word may occur in a context that precludes the possibility of taking it to stand for an idea without thereby being rendered insignificant—for example, the subject term in “the good things which God hath prepared for them that love him are such as eye hath not seen nor ear heard nor hath it entered into the heart of man to conceive.”

It was Berkeley’s view that the significance of propositions such as these last two was to be found not in the ideas the words might otherwise be said to stand for but in the purpose, or “design,” of the proposition. The design of this last example cannot be “to raise in the minds of men the abstract ideas of thing or good nor yet the particular ideas of the joys of the blessed. *The design is to*

make them more cheerful and fervent in their duty” (2.137 [italics added]; see 2.293, 3.292). Words, he held, “have other uses besides barely standing for and exhibiting ideas, such as raising proper emotions, producing certain dispositions or habits of mind, and directing our actions” (3.307). Thus, in his attacks on the semantic foundation of Locke’s doctrine of abstract ideas Berkeley came nearer than anyone since the Stoics to abandoning, or at least supplementing, the attempt to account for all linguistic meaning in terms of the relation between names and their bearers.

As for Locke’s semantics, Berkeley had reduced it to the unexceptionable principle of common sense that had no doubt prompted Locke’s theoretical claims, namely, we ought not to use words without knowing their meaning (1.78; 2.76). But he took Locke’s call for a new “doctrine of signs” quite seriously, summarizing his own (mostly anti-Lockean) semantic theory under that heading in *Alciphron* (1732), Dialogue VII, Section 14 (3.307). Like Bacon, Hobbes, and Locke before him, Berkeley thought of himself as providing philosophical remedies for the abuse of words, but he differed from them in making this the core of his philosophy, announcing that “the chief thing I do or pretend to do is only to remove the mist or veil of Words” (1.78; see 2.40). He set out explicitly to do just that at many points throughout his writings, but nowhere in a more concentrated form than in the introduction to the *Principles*.

In keeping with that aim Berkeley frequently urged his readers to contemplate ideas apart from words, maintaining that “if men would lay aside words in thinking ’tis impossible they should ever mistake save only in Matters of Fact” (1.84; see 2.40). He felt, therefore, that it was “absurd to use words for the recording our thoughts to ourselves: or in our private meditations” (1.62) and introduced his “Solitary Man” for the purpose of examining that pristine state of mind in a concrete example, “to see how after long experience he would know without words” (1.71; see 2.141–142). Such passages taken together suggest an anticipation of Wittgenstein’s attack on the notion of a private language, but Berkeley had second thoughts about the absurdity of the private use of words and seems to have concluded that “the Solitary Man would ... find it necessary to make use of words to record his Ideas if not in memory or meditation yet, at least, in writing without which he could scarce retain his knowledge” (1.75).

Berkeley’s ingenious linguistic analogy in his account of sense experience, the “Universal Language of Nature,” was first put forward in his *New Theory of Vision* (1709) and developed in several later works. Speaking strictly, it

belongs to his theory of knowledge rather than to his philosophy of language, but in the course of developing the analogy he often made interesting observations about language conceived in the ordinary sense (see, for instance, 1.228–233, 1.264–265).

MAUPERTUIS AND HIS CRITICS

In the latter half of the eighteenth century philosophical interest in language was concentrated among French philosophers. Under the influence of Condillac and the British empiricists they eventually came to consider the analysis of signification their most important task. Among the earliest figures in this development was Pierre-Louis Moreau de Maupertuis (1698–1759), who first published his brief *Réflexions philosophiques sur l'origine des langues et la signification des mots* in 1748. To some extent his position resembled those taken by Berkeley and by Condillac in his first book, *Essai sur l'origine des connaissances humaines* (1746); but Maupertuis seems to have written his *Réflexions* before he knew their work. Partly because of the author's fame as a scientist, the *Réflexions* attracted considerable attention and was commented on by Baron de L'Aulne Turgot (1750), Condillac (1752), Denis Diderot (1753), Voltaire (1753), and Maine de Biran (1815), among others.

Maupertuis conceived of the question of the origin of language very much as philosophers since Descartes had been conceiving of the question of the origin of knowledge. It was intended to give rise not to speculations about prehistoric man but rather to an analysis of the hypothetical circumstances of a man with fully developed faculties who has suddenly been deprived of all his memories and of all human society. Would such an individual frame a language at all? If he did so, what would be the stages of its development? By asking and answering such questions as these within the framework of his “metaphysical experiment,” Maupertuis expected to gain insight into the nature of language and its relation to the acquisition of knowledge. He began by imagining himself in the condition of the adult newborn. As soon as he had had two perceptions,

I should see that the one was not the other, and I should try to distinguish between them. And since I should have no ready-made language, I should distinguish between them by means of any marks whatever and might be satisfied with the expressions “A” and “B” as standing for the same things I now mean when I say “I see a tree,” “I see a horse.” Receiving new perceptions after-

wards, I could designate them all in that way.
(*Réflexions*, Sec. 7)

It is not clear whether his saying “A” to himself in this protolinguistic context is really separable from his act of individuating the perceptual event of his seeing a tree, but Maupertuis did consider “A” and “B” as signs of his perceptions and thus presented a nearly classic case of what Wittgenstein later described as a “private language.” The first development beyond those initial “signs” was recognized by Maupertuis as sufficiently radical to be described as “another language.” In Section 8 he wrote:

For example, in the preceding perceptions I should recognize that each of the first two had certain characteristics that were the same in both and that I could designate those by a single sign. Thus I should change my first simple expressions “A” and “B” into these: “CD” and “CE,” which would differ from the first only in that new convention, and which would correspond to the perceptions I now have when I say “I see a tree,” “I see a horse.”

Maupertuis's analysis proceeded in this way until he had introduced devices for discriminating kinds of perception, numbers of objects perceived, remembered and anticipated perceptions, and so on. His purpose in doing so, however, was to provide the background for a new philosophic method, which he applied most notably in his analysis of “the force of the proposition ‘there is ...’” Although in saying “there is a tree” I may seem to be making a claim that goes beyond the evidence of my perceptions, once language has been reconstructed on the basis of my perceptions alone, I am in a position to see that “there is a tree” is no more than an abbreviation for “I shall see a tree every time I go to that place.” This latter proposition in turn is reducible to the sequence “I was in a certain place,” “I saw a tree,” “I returned to that place,” “I saw that same tree again,” and so on (Secs. 24–28).

Eight years after writing the *Réflexions* and having meanwhile read the French translation of Berkeley's *Dialogues* (1750), Maupertuis readily admitted the similarity of his metaphysics to Berkeley's and rested his claims of independent importance on having introduced an analysis of language as the means to that end. “The point is that this philosopher [Berkeley] attacks the system of our errors only by parts. He demolishes the structure at the top, and we undermine its foundations. This is a structure quite different from that famous tower the erection of which on the Plains of Shinar was prevented by the confusion of tongues; this one is not erected *except by abusing or forgetting the meaning of words*” (*Reply to*

Boindin, Sec. II, in *Oeuvres*, 1756 ed.). Berkeley's own attitude was, of course, much the same; but the *Dialogues* alone among his major works fails to bring that out.

Several of Maupertuis's critics, most notably Turgot, attacked the hypothesis on which he rested his inquiry: "A solitary man such as Maupertuis imagines ... would not try to find marks with which to designate his perceptions. It is only when confronted with other people that one looks for such marks. From this there follows what is obvious in any case, that the first purpose and first step of language are to express objects and not perceptions" (*Remarques critiques*, Sec. 7). Only Maine de Biran among Maupertuis's critics defended his use of the private-language hypothesis (*Note sur les Réflexions*, Sec. V).

CONDILLAC

Étienne Bonnot de Condillac (1715–1780) wrote his first book, *Essai sur l'origine des connaissances humaines* (1746), in an effort to do what he felt Locke might have done if he had not "realized too late" the importance for epistemology of the material in Book III of his *Essay*, "Of Words" (Locke's *Essay* 3.9.21). Locke had "treated only in his third Book what should have been the subject matter of the second" (*Essai*, edited by G. Le Roy, 1.5a). Condillac acknowledged its historical value: Locke seemed to him to have been "the first to have written on this material as a genuine philosopher. I felt, nevertheless, that it had to form a considerable portion of my own work, both because it can be viewed in a novel, more extended way and because *I am convinced that the use of signs is the principle that discloses the source [développe le germe] of all our ideas*" (1.5b; italics added). Condillac thus became the first modern philosopher to found his theory of knowledge, and consequently his entire philosophy, on considerations of signification and language, considerations that occupied him throughout his career and that shaped French philosophy for at least fifty years afterward.

Like Locke, Condillac denied that the ideas produced in sensation alone constitute a kind of knowledge, but he began his divergence from Locke in his account of the acquisition of knowledge on the basis of such ideas. "The *sole* means of acquiring knowledge is to trace our ideas back to their origin, to observe their generation, and to compare them under all possible relations. This is what I call *analysis*" (1.27a). Analysis consists in discriminating and ordering elements that are presented confusedly and simultaneously and thus requires the introduction of interrelatable signs for those elements. On these observations Condillac based his leading principle that "every

language is an analytic method and every analytic method is a language" (2.419a).

This has the look of a vicious circle. Analysis is said to be a necessary condition of knowledge, and language to be necessary for analysis; but surely knowledge is also necessary for the formation of a language. Condillac attempted to break this circle by introducing the notion of an innate language, which he called the language of action. "The elements of the language of action are born with man, and those elements are the organs given us by the author of our nature. Thus there is an innate language although there are no innate ideas. Indeed, it was necessary that the elements of some sort of language, prepared in advance, should precede our ideas, since without signs of some kind it would be impossible to analyze our thoughts" (2.396b).

In its most rudimentary form this "language" consists simply in overt reactions: "our external conformation is set to represent everything that takes place in our soul" (ibid.). Involuntary expressions of fear, pain, desire, and so on are not elements of analysis for the individual producing them, but observers of his responses can, as a result of observing the order of events making up his responses, see analyzed for them what is simply gross experience for the respondent. "Men begin to 'speak' the language of actions as soon as they feel anything, and they speak it then without having any plan of communicating their thoughts. They form the plan of speaking it in order to make themselves understood only when they notice that they have been understood" (2.397a). The usefulness of results gained by this means stimulates a natural feedback process of development on "the principle of analogy," and the language of action is made more effective by the gradual transformation of "natural" and "accidental" signs into "signs of institution," the most convenient of which are articulate sounds (1.60b–62a). The origin of language, discussed as an independent topic by many of his contemporaries and successors, is thus an essential consideration in Condillac's epistemology.

Signs of institution, including, of course, words, are themselves natural in the sense that as a language develops, they are framed on analogy with more primitive elements in that same language (and ultimately with elements of the language of action). The principle of analogy is in fact a necessary ingredient in any usable language (compare Bacon's doctrine of "emblems"). "Imagine an absolutely arbitrary language, such that analogy had determined neither the choice of words nor their various senses. That language would be an ununderstandable gibberish" (2.471a). If the principle of analogy

remained unimpaired in ordinary languages, “we would reason as nature teaches us to reason, moving effortlessly from discovery to discovery.” But every ordinary language has been impaired to some extent by the intrusion of words that have the roots of their analogy in other languages. (A similar line of reasoning had led Leibniz to praise the German language as a natural “philosophical characteristic.”) Perhaps, then, the principle of analogy can be retained in a perfectly unadulterated form only in a highly artificial language, such as algebra, which Condillac describes as “the language of mathematics.”

Since language of some sort is a necessary condition of knowledge, it is a mistake to maintain, as Locke had done, that the primary purpose of language is to communicate knowledge. “The primary purpose of language is to analyze thought. In fact we cannot exhibit the ideas that coexist in our mind successively to others except in so far as we know how to exhibit them successively to ourselves. That is to say, we know how to speak to others only in so far as we know how to speak to ourselves” (1.442a). It is a consequence of this view that the art of thinking, or logic, reduces to the art of speaking.

Although a thought is not a succession in the mind, it has a succession in discourse, where it is decomposed into as many parts as there are ideas making it up. Then we can observe what it is we do when we think, we can give an account of it, we can, consequently, learn how to conduct our reflective thought. In this way thinking becomes an art, and that art is the art of speaking. (1.403b)

Condillac’s view of the connection of thought and language was reinforced by his observations on “abstract general ideas.” “When, for example, I think about *man*, I cannot consider anything in that word except a common denomination, in which case it is perfectly plain that my idea is in some way circumscribed in that name, that it extends to nothing beyond the name, and that, consequently, it is only that name itself” (2.401b). Thus the clarity and precision of abstract ideas “depends entirely on the order in which we have produced the denominations of classes. Therefore, there is only one means of determining ideas of this sort, and that is to produce a well-made language” (ibid.). Abstract general ideas, however, are the principal ingredients of reasoning, and Condillac was even ready to say that “to speak, to reason, to produce abstract or general ideas for oneself, are at bottom one and the same thing” (2.402a). His consideration of abstract ideas, then, was one more “proof that we

reason well or badly only because our language is well or badly made” (ibid.).

All intellectual progress, on Condillac’s view, depended on and in part consisted in establishing a “well-made language,” and “a science, properly treated, is nothing other than a well-made language” (1.216a). The one perfectly well-made language so far established, he thought, was mathematics, which he examined from this point of view in his last book, *La langue des calculs* (1798). One reason why Condillac was prepared to identify a science with a well-made language is to be found in his doctrine of propositions. All that remains to be done in a science once the appropriate language has been established is the mechanical exposition of the truths proper to that science. The exposition is mechanical because “a proposition is only the unfolding of a complex idea in whole or in part,” and since a proposition “in which one and the same idea is affirmed of itself” is an identical proposition, “every truth is an identical proposition” (2.748a). An identical proposition may, however, be instructive for some persons, namely, those who observe “for the first time the relation of the terms out of which it is formed.... Thus a proposition may be identical for you and instructive for me” (2.748b). Nevertheless, “if in all the sciences we could equally trace the generation of the ideas and everywhere apprehend the true system of the things, we should see one truth give birth to all the rest, and we should find the abridged expression of all we know in this identical proposition: *the same is the same*” (2.749b).

Condillac’s influence extended not only to philosophers but also to the great chemist Antoine Lavoisier (1743–1794), who in his *Méthode de nomenclature chimique* (with Louis-Bernard Guyton de Morveau, 1787) and *Traité élémentaire de chimie* (1789) wholeheartedly adopted Condillac’s notion of a science as a well-made language. Operating under this notion, Lavoisier introduced such technical terms as “phosphoric acid” and “sulphuric acid” in a successful attempt to initiate the development of the language of modern chemistry on Condillac’s principle of analogy.

LAMBERT, HAMANN, AND HERDER

In the century between Leibniz and Wilhelm von Humboldt, philosophy of language in Germany was concentrated in the writings of three men: Johann Heinrich Lambert (1728–1777), Johann Georg Hamann (1730–1788), and Johann Gottfried Herder (1744–1803).

Lambert was a distinguished mathematician and the first man to follow Leibniz’s lead in his contributions to

logic, the most important of which was the earliest attempt at a calculus of relations. His work in the philosophy of language appeared in his *Neues Organon* (1764), especially Part III, “Semiotik, oder die Lehre von der Bezeichnung der Gedanken und Dinge.”

In philosophy of language, as in logic, the principal influence on Lambert was that of Leibniz, as may be seen in his preoccupation with the effect of language on thought and knowledge and with the possibility of controlling and improving that effect. Various natural languages impose various structures on our knowledge, but every natural language is fundamentally the product of prephilosophical, prescientific humankind. When we attempt to use such a language in advanced intellectual activities, we must submit our thought to the tyranny of usage (III, 1). We are thus led to seek an artificial language that from its inception could be entirely subjected to the needs of the intellect.

Lambert’s attitude toward such artificial languages differed, however, from Leibniz’s and constitutes a significant development in this line of thought. Great men, he observed, have worked at the project of a simple, perfectly regular and precise rational language, but without notable success. In any case, the adoption of such a language would be practically impossible (III, 2, 330). If we then revert to natural languages, however, we find that, strictly speaking, we cannot adopt any single one of them as a foundation for knowledge. There are, in the first place, conflicting usages even within a single natural language, some of which would have to be more or less arbitrarily ruled out; and, in the second place, any set of usages finally adopted would inevitably continue to undergo changes within the natural language of which they were a part.

Once we recognize that we do thus necessarily deviate to some extent from any given language in adapting it to intellectual purposes, it is apparent that we ought to do so consciously and under the guidance of preexamined criteria. The criteria developed and employed by Lambert were, he observed, the sort that might have served as the operative rules of a philosopher’s artificial language. In fact, he seems to have elevated Leibniz’s projected “universal characteristic” to the status of an ideal language, the principles of which are approximable to varying degrees but never fully realizable. He described his detailed examination of language as one that made a point of not distinguishing sharply between “actual and possible languages,” meaning thereby that his approach to natural language was a mixture of description and prescription in which he attempted to point out those

aspects of the actual language which were already accommodated to certain requirements of the ideal and to suggest ways in which those aspects might be enhanced and extended without introducing radical reforms that had little chance of acceptance.

The fundamental criterion employed by Lambert in his evaluation of sign systems in general and of natural languages in particular was the interchangeability of “the theory of the signs” and “the theory of the objects” signified, the degree of interchangeability marking the extent to which the signs approximated the fundamental ideal of being “scientific” (III, 23–24)—he cited musical notation as an example of a particularly close approximation. It seems evident that this fundamental criterion, which with its many corollaries pervades Lambert’s philosophy of language, constituted his adaptation of Leibniz’s doctrine of “expression.” Besides systematic general chapters on various aspects of language, Lambert’s “Semiotik” includes specific examinations of the character and function of various parts of speech and of the philosophical significance of etymological and syntactic interrelations among words.

Lambert and Hamann shared the conviction that the character of language was a topic of the greatest importance for philosophy, but they differed in almost every other important respect. Hamann’s writings are undisciplined, obscure, and strongly colored by religious mysticism. Philosophically he was a forerunner of romanticism and existentialism, consciously rejecting most of the attitudes of the Enlightenment.

To the extent to which Hamann’s philosophy exhibits a structure, it centers on his views on language, so much so that he himself called it verbalism (*Schriften*, edited by C. H. Gildemeister, 5.493–495). In almost everything he had to say about language, however, he opposed his contemporaries—Lambert (and the Leibnizian tradition) implicitly, Herder explicitly. The fundamental thesis of Hamann’s verbalism is that ordinary natural language does and should take philosophical precedence over all technical or abstract language. Occasionally he wrote as if his basis for this claim was that God had employed such language as the instrument of revelation (*Schriften*, edited by F. Roth and G. A. Wiener, 1.85–86, 1.99), but he seems to have had more generally evaluable reasons for it as well. He evidently felt that the opposition between the rationalists and the empiricists of the Enlightenment was irresolvable largely because of the reliance of both parties on introspection. The special importance of ordinary language in this connection was that it constituted a medium in which the operations of reason and experi-

ence were united and made publicly accessible. The operations of reason, indeed, consisted entirely in linguistic operations (Roth and Wiener, 6.15 and 6.25; Gildemeister, 5.515, 7.9). Philosophy, however, had traditionally adulterated what should have served as its principal source and instrument. Hamann brought this out in a characteristic attack on Immanuel Kant's abstract, technical language in the first *Critique*:

While geometry fixes and fictionalizes the ideality of its concepts of points without parts, of lines and planes conforming to ideally divided dimensions, by means of empirical signs and figures, metaphysics misuses all the word-signs and figures of speech of our empirical knowledge as mere hieroglyphs and types of ideal relations and as a result of this learned mischief transforms the straightforwardness [*Biederkeit*] of language into such a senseless, whirling, unsteady, indeterminable something (= *x*), that nothing remains but a windy murmuring, a magical shadow-play, at best ... the talisman and rosary of a transcendental superstition regarding *entia rationis*, their empty sacks and slogan. (Roth and Wiener, 7.8)

It was not only Kant's misuse of language that attracted Hamann's criticism but more especially his utter neglect of language as a topic for inquiry, which from Hamann's point of view vitiated Kant's claim to have provided a critique of reason. To point up the folly of such neglect, he tried to show that at various crucial junctures in his argument (as in the deduction of the categories) Kant had uncritically relied on certain linguistic conventions and that what he had called paralogisms and antinomies of reason really had their roots in the misuse of language.

Hamann based his doctrine of the preeminence of ordinary language not only on its value as a subject for philosophical inquiry but also on the fact that it alone among types of language was "objectively given." As such it served as the "womb" of reason and of all specialized, abstract languages designed to aid the operations of reason. Moreover, since ordinary language thus constituted the ultimate link between language and reality, all such abstract languages must be held finally accountable to it, that is, translatable into it.

As a philosopher of language, Herder is best known for his prize essay on the origin of language (1771), a topic with which this entry is generally not concerned. Herder's essay, however, occupies a position of special importance among hundreds of similar productions by

eighteenth-century philosophers, for it began the trend away from the speculative problem of origin and toward the scientifically more accessible problems of the development of language. (It was praised for that reason by several of the great linguists of the nineteenth and twentieth centuries, such as Grimm, Theodor Benfey, Edward Sapir, and Otto Jespersen.)

Ostensibly Herder was adjudicating between two rival accounts of the origin of language, but his real purpose was to dismiss the problem as senseless. The two theories at issue were those of special divine creation and of deliberate human invention of language, the former as represented in J. P. Süssmilch's work and the latter associated primarily with Jean-Jacques Rousseau's second *Discours*. Herder took reason to be the defining characteristic of man and argued in support of Hamann's position that the operation of reason and the use of language were inseparable. He then drew the obvious conclusion that if God had created what was genuinely man, He had created a language-using animal and no special divine creation of human language was conceivable. By the same token, animals correctly describable as men could not conceivably have invented language. Thus the question of how and when humans came to use language was misconceived, although the question of how primitive human languages developed was well worth considering. Hamann ridiculed Herder's argument, with justification. It seems probable, however, that the argument was intended as irony, to deflate the pretensions of the theorists rather than to refute the theories.

THE "IDÉOLOGUES."

Antoine Louis Claude Destutt de Tracy (1754–1836) devised the name *idéologie* for the new "science of the analysis of sensations and ideas." One section of the Second Class of the Institut National (founded in 1795) was devoted to that science in lieu of the prescientific inquiry known as metaphysics, and Destutt de Tracy and other philosophers associated with the work of that section became known as *idéologues*. For about eight years, until Napoleon Bonaparte abolished the Second Class of the Institut in the reactionary atmosphere of the First Empire, the *idéologues* were the dominant philosophical group in France. They thought of themselves as working in a field that had been opened by Locke and first thoroughly explored by Condillac, whose most original contribution was considered to be his discovery that language was as essential to the more fundamental processes of thought and analysis as it was to communication. Although part of at least Destutt de Tracy's interest in lan-

guage was directed specifically to *grammaire générale* (see below), the *idéologues* followed Condillac in considering language a topic of importance in every area of philosophical inquiry.

The *idéologues* resented being thought of as disciples of Condillac, however, and while they did, professedly, share some of his broad philosophical convictions, much of what they had to say about language (as about other topics) involved substantial revision or outright rejection of Condillac's specific doctrines. There seems to have been some tendency for the revisions to take the form of a generalization of Condillac's doctrines, notably from a concern with language to a concern with signs of all sorts. Thus, in a representative passage of his *Rapports du physique et du moral* (delivered in 1796), Pierre-Jean-Georges Cabanis (1757–1808) purported to be defending and explicating Condillac's central claim that every language was an analytic method by arguing that "one distinguishes among sensations only by attaching to them signs that represent and characterize them; one compares them only in so far as one represents by signs either their resemblances or their differences." Of course, Cabanis pointed out, taking this account as explicative of Condillac's claim required taking "language" in "the broadest sense," as meaning "the methodological system by means of which one pins down [*fixe*] one's own sensations" (*Oeuvres*, edited by Claude Lehec and Jean Cazeneuve, p. 157).

The question of the nature and epistemological function of signs (including linguistic signs) took on critical importance for the *idéologues* as a result of Destutt de Tracy's *Mémoire sur la faculté de pensée* (delivered in 1796), prompting them to set "the influence of signs on the faculty of thought" as the subject for the first essay competition sponsored by the section on the analysis of sensations and ideas. The best entries were *Des Signes envisagés relativement à leur influence sur la formation des idées* by Pierre Prévost, *Introduction à l'analyse des sciences, ou de la génération, des fondements, et des instruments de nos connaissances* by P.-F. Lancelin, and *Des Signes et de l'art de penser, considérés dans leurs rapports mutuels* by Marie-Joseph Degérando (1772–1842). Degérando's essay won the prize and was published in an expanded four-volume version in 1800. In it some of the principal issues in the philosophy of language of the seventeenth and eighteenth centuries were subjected to a final scrutiny, partly as a result of the historically apt questions provided by the *idéologues* as a guide for the essayists:

(1) Is it really the case that sensations can be transformed into ideas only by means of signs? Or, what comes to the same thing, do our first ideas depend essentially on signs? (2) Would the art of thinking be perfect if the art of signs were perfected? (3) In those sciences in which there is general agreement as to the truth, is this because of the perfection of the signs employed in them? (4) In those branches of knowledge that provide inexhaustible fuel for dispute, is the division of opinion a necessary effect of the inexactitude of the signs employed in them? (5) Is there any means of correcting badly made signs and of rendering all sciences equally susceptible of demonstration? (*Mémoires de l'Institut National des Sciences et Arts. Sciences morales et politiques*, 1.i–ii)

Question (1) was on a thesis of *idéologie* itself, as may be seen in the passage from Cabanis quoted above. Degérando's answer was complex, but it was sufficiently affirmative to mark him an *idéologue*. On the one hand he felt that the mind needed no signs but merely an act of attention in order to pin down its sensations. On the other hand, "I shall give the name ['sign'] to every sensation that excites an idea in us in virtue of the association obtaining between them. Note carefully that it is not the sensation as such to which the name is given; it gets the name only in respect of the function it performs. Thus I shall say, for example, that the smell of a rose is the sign [not of the rose but] of the ideas of color and of form that the smell excites" (1.62–63). He distinguished between such prelinguistic signs and linguistic signs by pointing out that while the former "excite" ideas in us but attract attention to themselves, the latter lead our attention away from themselves to the ideas they have been made to signify, a formulation that constituted a refinement of the traditional distinction between natural and conventional signs.

In his detailed answers to questions (2) and (5) Degérando carefully criticized the many attempts at universal characteristics, calculi of reason, and philosophical languages that had been made by philosophers of the Renaissance and the Enlightenment. He laid down five criteria for such systems: (a) unambiguous relations between signs and signified ideas; (b) relations among signs exactly analogous to relations among signified ideas; (c) simplicity, that is, minimum number of primitives (*conditions premières*), each sign as abbreviated as possible, perspicuity of the sign system as a whole; (d) distinctness among signs of different sorts and among

syntactic relations of different sorts; (e) as many distinct sorts of signs as distinct sorts of ideas to be signified (4.353–355). The only hopes of satisfying such criteria, he maintained, lay along four different lines, or “systems for philosophical language.” Having examined each in detail, he concluded that all were in some respects unacceptable. Like Lambert, however, he suggested that a judicious application of the principles of such systems might produce some improvement in natural languages for philosophical purposes (4.355–415).

Perhaps even more important historically than his arguments against the feasibility of such artificial languages was his attack on the attitudes underlying them. It had usually been assumed that such a language would be international, and, indeed, if it were not, it would fail to achieve a good part of its purpose. But, Degérando maintained, there was no feasible means by which to establish it internationally, and even if it were established, it would soon be modified into separate dialects in various localities (3.557). Worst of all, the notion is pernicious, for such a language could at best be the instrument of communication exclusively among the learned and would thereby tend to separate them further from those they ought to instruct (3.572).

The fundamental mistake giving rise to all such schemes, according to Degérando, is the confusion of “the *method of reasoning* employed by the mathematicians with the *mechanical processes* of their calculations. Their method, as I have shown ..., they do have in common with the metaphysicians,” but the mechanical processes of their perfectly satisfactory artificial languages are the result of “the relative simplicity of the ideas on which they operate” (4.447–451). Other *idéologues*, particularly Destutt de Tracy, joined in this thoroughgoing repudiation of artificial languages for philosophy (see, for instance, *Mémoires de l’Institut*, Vol. III).

Questions (3) and (4) together called for an examination of Condillac’s contention that a science was to be identified with a well-made language. Cabanis, himself a scientist, and Destutt de Tracy had frequently made significant use of this doctrine, but Degérando rejected it in a way that seems symptomatic of the end of the Enlightenment conception of a science. Some of the basis for his answers to these questions is evident in his answers to questions (2) and (5). “A well-made language,” he maintained, “proclaims and presupposes a science that is already well advanced,” thus adopting the Cartesian position on this issue rather than the Leibnizian. “We shall say that the great art of perfecting a science consists above all in making better observations and only *then* adopting a

better language—i.e., one that is better suited to the observations that have been assimilated” (3.150–151). “The nomenclature of a science is related to the science itself as monuments are related to history: it preserves what is, but it can neither predict what is not yet nor unfold the future” (3.199).

Degérando resembled other *idéologues* more closely, however, in his view that improvements in philosophy—that is, in the analysis of sensations and ideas—did depend on a thorough examination of the natural language in which it was carried out. His own rather novel, never-realized scheme for accomplishing this was the construction of a philosophical dictionary.

It has been recognized that we can have clear ideas only in possessing a well-made language, and that a language can be well-made only in so far as we have reformed the most familiar operations of the mind from the very outset, only in so far as we have grasped the relation that interconnects them all. That being the case, we have felt the need of remaking the language in its entirety and, in some sense, recommencing the education of the human mind. The surest and perhaps the most truly efficacious means of accomplishing this great project would be, I think, the formation of a philosophical dictionary truly worthy of the name—one, that is to say, that would in some sense be a genealogical tree of our ideas and of the signs we use. Such a dictionary would be a sequence of definitions strictly bound to one another. Each notion would be defined in it by showing how it was acquired, or at least how it should have been acquired. The mind would find itself naturally led to *create* the words rather than seeking merely to *explain* them to itself.... The dictionary I propose would have an aim altogether different [from that of ordinary dictionaries]. In it one would seek to explain not so much how we speak as how we think; the conventions of the language would be presented in it as *results*, not as *principles*. ... [This dictionary would not be arranged in alphabetical order but] it would be a book, a history. The order of facts would be the only order observed in it. It would not ... be designed to be consulted occasionally, but it would have to be the object of a connected reading.... A definition would never be offered in it except in accordance with one general rule—that of determining an idea by means of tracing

it back to the ideas that must have preceded it in the age when language was instituted among men.... The dictionary would thus in some sense embrace the history of mankind and would serve as a natural introduction to all the sciences. The study of it would be necessary for all who wished to think well, and its formation would be one of the noblest undertakings of philosophy. (4.80ff.)

What little influence the *idéologues* had is somewhat more noticeable in British than in Continental philosophy of the nineteenth century, partly because of the interest of some of the Scottish commonsense philosophers in their work.

UNIVERSAL GRAMMAR

Among the most important and distinctive influences on the philosophy of language of the Enlightenment was the development of universal grammar. In the broadest sense of the term it was, as defined by James Harris (1709–1780), “that grammar which without regarding the several idioms of particular languages only respects those principles that are essential to them all” (*Hermes, or a Philosophical Inquiry concerning Language and Universal Grammar*, 1751, Book I, Ch. 2). Although it resembles the speculative grammar of the Middle Ages in some of its basic assumptions, universal grammar seems to have had an independent origin that may with reasonable accuracy be dated 1660, the year in which Arnauld and Claude Lancelot published the *Port-Royal Grammar—Grammaire générale et raisonnée*.

Lancelot was a grammarian in the scholastic (rather than humanist) tradition who provided the subject matter that Arnauld presented in accordance with Descartes’s method, believing that he was thereby “developing in grammar a branch of Cartesianism” (p. 137). In grammar, as in every subject, the method consisted fundamentally in “beginning with the most general and simplest matters in order to proceed to the least general and most complex,” and in the study of language one therefore had to begin with principles and elements common to all languages in order to proceed to the study of one’s own and other particular languages. Thus, universal grammar, as Arnauld (and many of his successors) conceived of it, was an investigation of language (*langage*) designed as a propaedeutic to the study of languages (*langues*). In practice, however, the elements and principles of universal grammar tended to be those of traditional Latin grammar, and thus many of the so-called universal grammars,

at least before Condillac, are of little value either to linguists or to philosophers.

More important than the content of the early treatises on universal grammar, however, is the connection they established between grammar and philosophy, especially in France, where universal grammar dominated linguistic studies for 150 years following the *Port-Royal Grammar*. César Chesneau Dumarsais (1676–1756), the foremost of the universal grammarians between Arnauld and Condillac, maintained that “grammarians who are not philosophers are not even grammarians” (*Véritables Principes de la grammaire*, 1729, 1.201), and men engaged in the inquiry at that time styled themselves *grammairiens-philosophes*. Dumarsais seems often to have thought of “philosophy” in connection with grammar as no more than a certain scientific attitude (see, for instance, his article “Grammairien” in the *Encyclopédie*), but he also held some of the views that were to serve as the basis for a more strictly philosophical grammar, as can be seen in his explanation that “grammar has a necessary connection with the science of ideas and reasoning because grammar treats of words and their uses and words are nothing but the signs of our ideas and our judgments” (1.201).

The *grammairiens-philosophes* began to be more markedly philosophers than grammarians beginning with the articles on grammatical topics in the *Encyclopédie*. Although Dumarsais was in general charge of them, several were written by philosophers such as Voltaire, Diderot, and Turgot; and the articles as a group contain less information on the announced topics than they do discussions of philosophical questions more or less vaguely associated with those topics. Nicolas Beauzée (1717–1789), one of the authors of those articles, defended the new approach to grammar in his *Grammaire générale* (1767): “Why should one think metaphysics out of place in a book on universal grammar? Grammar ought to expose the foundations—the general resources and the common rules—of language, and language is the exposition of the analysis of thought by means of speech. No aim is more metaphysical or abstract than that” (*Préface*, p. xvii).

In the works of Condillac, the emphasis was no longer on the propriety of taking a philosophical approach to grammar but rather on the fundamental importance of universal grammar as an inquiry serving the purposes of philosophy itself. In the “Motif des études” introducing his course of studies for the prince of Parma, Condillac described grammar as “a system of words that represents the system of ideas in the mind

when we wish to communicate them *in the order and with the interrelations we apperceive.*” Consequently, as he remarked in the “Objet de cet ouvrage” preceding his *Grammaire* (1775), he regarded grammar “as the primary division of the art of thinking. In order to discern the principles of language we must observe how we think; we must seek those principles in the analysis of thought. But *the analysis of thought is quite complete in discourse*, with more or less precision depending on the greater or less perfection of languages and the greater or less exactness of mind on the part of those who speak them. This is what makes me think of languages as so many analytic methods.”

Condillac’s elevation of universal grammar to the status of a fundamental philosophical inquiry marked the beginning of a new phase in the development of universal grammar, but his view of it was no more than a natural consequence of the then well-established belief that the construction of an absolutely universal grammar for all languages was a feasible undertaking. If language depicted thought and all languages shared a set of elements and principles, then the study of those common elements and principles would provide a science of human thought.

For Condillac’s successors, the *idéologues*, who took the analysis of sensations and ideas to be the whole of philosophy, universal grammar became *the* philosophical method. As Destutt de Tracy put it, “this science may be called *idéologie* if one attends only to the subject-matter, *universal grammar* if one has reference only to the method, or *logic* if one considers only the goal” (*Éléments d’idéologie*, 1801, 1.5). It was in accordance with this conception of philosophy that the traditional chairs of logic and metaphysics in the *écoles centrales* of France were replaced in 1795 with chairs of universal grammar, which “by offering instruction in the philosophy of language would serve as an introduction to the course in private and public morality” (*Éléments, Préface*, p. xxiii).

Destutt de Tracy devoted the second part of his *Éléments d’idéologie*, some 450 pages, to a presentation of universal grammar suited to the purposes of the new course. Although he did occasionally cite parallel examples in other European languages and stress the value of knowing several languages, his principal interest was in what might fairly be described as the analysis of ordinary French. As an *idéologue* he was committed to provide analyses that would in every case disclose the signified idea (or sensation). His first step in establishing the conditions for such an analysis was to insist that the unit of signification was not the word or phrase, no matter how

complex, but only the proposition, the linguistic device expressive of a judgment. If one simply utters the words “Peter,” “to be not tall,” we say that it means nothing, it makes no sense, although if one merely changes the form of the verb so that one says “Peter is not tall,” thereby expressing a judgment, we can discern in what he says signs of his having an idea of Peter and an idea of his height (2.29–33).

Thus Destutt de Tracy committed himself to providing ideological analyses only if the linguistic entity to be analyzed occurs within a proposition. Even so, locating the signified idea sometimes required considerable ingenuity, as in his attempt to analyze all “conjunctions” in such a way as to show not only two propositions related by each conjunction but also the idea signified by each.

One can say as much regarding the conjunctions we use in asking questions, even though they might at first seem not to connect two propositions, because the first is suppressed. Thus when I say “how did you get in again?,” “why did you leave?,” I am really expressing these ideas: “I want to know [*Je demande*] *how* you got in again,” “I want to know *why* you left.” And when we unfold the sense of those conjunctions the result is: “I want to know *a thing that is the manner in which* you got in again,” “I want to know *a thing that is the reason for which* you left.” (2.136)

In Destutt de Tracy considerations of grammar were entirely subject to the demands of ideological analysis, as is plain not only in the structure of his final analyses above but also in his readiness, quite unusual even among *grammairiens-philosophes*, to revise the classifications of traditional grammar (treating the “adverbs” *comment* and *pourquoi* as “conjunctions”) when philosophical considerations seemed to call for their revision. When his volume devoted to universal grammar appeared in 1803, the experimental substitution of universal grammar for logic and metaphysics in the schools had already been abandoned, along with the *idéologues’* highest hopes for revolutionizing philosophy.

In Germany, Christian Wolff and Lambert had taken notice of universal grammar, but the movement had no appreciable impact on philosophy. In England it affected mainly the work of Harris, of James Beattie (1735–1803), and of John Home Tooke (1736–1812), all of whom developed universal grammar far less as a philosophical than as a philological inquiry. By the beginning of the nineteenth century, universal grammar was rapidly going out of fashion as a branch of philosophy, even in France, despite the last efforts of the *idéologues*.

THE NINETEENTH AND TWENTIETH CENTURIES

BENTHAM

Jeremy Bentham (1748–1832) did almost all his work in philosophy of language during the last twenty years of his life, primarily under the influence of Locke, the *idéologues*, and the universal grammarians. In a passage distinctly reminiscent of Locke's call for the development of "the doctrine of signs," Bentham expressed his own conviction that "a demand exists for an entirely new system of *Logic*, in which shall be comprehended a *theory of language*, considered in the most general point of view" (*Works*, edited by John Bowring, 8.119–120). His belief in the importance of a theory of language within a system of logic seems to have made an impression on J. S. Mill and may mark the beginning of the return to a view of the interrelations of logic and language more like that prevailing in the later Middle Ages than like that of the eighteenth century.

Universal grammar constituted a part of Bentham's plan for fulfilling the demand he had recognized, and his account of its subject matter is modeled explicitly on what he considered the "pioneering" work of Tooke (see, for instance, 8.187–188). Unlike Tooke, however, Bentham was inclined to consider it a branch of philosophical rather than philological inquiry and echoed the *idéologues* in his claim that within "the field of universal grammar it is not enough for a man to look into the books that are extant on the subject of grammar, whether particular or universal—he must look into his own mind" (10.193). He also followed the *idéologues*, Degérando in particular, in rejecting Condillac's view that languages and analytic methods were identifiable. On the one hand, he held, the analysis of experience on the most primitive level was dependent on the prelinguistic faculty of attention; on the other hand, "every name, which is not, in the grammatical sense, a *proper* name, is the sign and result" of an act of *synthesis* rather than of analysis (8.75; 8.121–126). Bentham did, however, cite Lavoisier's Condillac-inspired reform of the language of chemistry as a prime example of the practical value of the philosophy of language (3.273).

On more strictly semantic questions Bentham occasionally wrote as if he had simply absorbed and to some extent clarified the doctrines of Locke's Book III, but when his most distinctive refinements of Locke are brought together, they mark a genuine advance in the history of semantics. He was in general agreement with Locke that "language is the sign of thought, an instru-

ment for the communication of thought from ... the mind of him by whom the discourse is uttered [to another mind].... The immediate subject of a communication made by language is always the state of the speaker's mind." The crucial doctrine of immediate signification, which in Locke had been obscured by his vacillating treatment of it, was explicated by Bentham as follows:

In both these cases ["I am hungry," "That apple is ripe"], an object other than the state of my own mind is the subject of the discourse held by me, but in neither of them is it the *immediate* subject. In both of them the *immediate* subject is no other than the state of my own mind—an *opinion entertained by me in relation to the ulterior object or subject*. ... [Language] may be the sign of ... other objects in infinite variety, but of this object [the utterer's state of mind] it is always a sign, and it is only through this that it becomes the sign of any other object. (8.329–331)

Since, however, "communication may convey information purely, or information for the purpose of excitation" (8.301), the immediately signified state of the speaker's mind may be either "the state of the *passive* or *receptive* part of it, or the state of the *active* or *concupiscible* part" (8.329). Bentham described the use of language as a medium of communication as its "transitive" use. "By its *transitive* use, the collection of these signs is only the vehicle of thought; by its *intransitive* use, it is an instrument employed in the creation and fixation of thought itself." Consequently the transitive use of language "is indebted for its existence" to the intransitive use (8.228–229, 8.301).

Partly because he had begun with "thoughts" rather than Lockean ideas as the immediate significata of linguistic signs, and perhaps also because of the similar position taken in Destutt de Tracy's universal grammar, Bentham recognized not words but propositions as the elements of significance.

If nothing less than the import of an entire proposition be sufficient for the giving full expression to any [but] the most simple thought, it follows that, no word being anywhere more than a fragment of a proposition, *no word is of itself the complete sign of any thought*. It was in the form of entire propositions that when first uttered, discourse was uttered.... *Words may be considered as the result of a sort of analysis—a chemicological process for which, till of a*

comparatively much later period than that which gave birth to propositions, the powers of the mind were not ripe. (8.320–323; italics added)

“In language, therefore, the *integer* to be looked for is an entire proposition” (8.188).

Many of Bentham’s predecessors, but especially Locke, had inveighed against the philosophers’ tendency to “take words for things.” Bentham’s refinement and extension of this notion into a doctrine of “linguistic fictions” is his most distinctive contribution to philosophy of language. He began by taking the evidently unprecedented step of defining extralinguistic elements in terms of the functions of certain elements of language.

An *entity* is a denomination in the import of which every subject matter of discourse, for the designation of which the grammatical part of speech called a noun-substantive is employed, may be comprised.... A *real* entity is an entity to which, on the occasion and for the purpose of discourse, existence is really meant to be ascribed.... A *fictitious* entity is an entity to which, though by the grammatical form of the discourse employed in speaking of it, existence be ascribed, yet in truth and reality existence is not meant to be ascribed.

Thus the noun-substantive “motion” in “that body is in motion” is the name of a fictitious entity, since “this, taken in the literal sense, is as much as to say—Here is a larger body, called a motion; in this larger body, the other body, namely, the really existing body, is contained.” While he insisted that linguistic fictions stood in need of what he called exposition, he also maintained that they were contrivances “but for which language ... could not have existence” (8.195–199).

The mode of exposition to which linguistic fictions were to be subjected was called paraphrasis, which “consists in taking the word that requires to be expounded—viz the name of a *fictitious* entity—and, after making it up into a *phrase*, applying to it another phrase, which, being of the same import, shall have for its principal and characteristic word the name of the corresponding *real* entity” (8.126–127). Since all words designative of nonphysical entities involved linguistic fictions, most of the work of philosophy, Bentham thought, would consist in such exposition of language.

In his *Principles of Morals and Legislation*, Chapter X, Bentham recommended a method of starting philosophical inquiry that was later to be employed and advocated

by J. L. Austin. “I cannot pretend,” Bentham said of his catalogue of motives in that chapter, “to warrant it complete. To *make sure* of rendering it so, the *only* way would be to turn over the dictionary from beginning to end; an operation which, in a view to perfection, would be necessary for more purposes than this” (italics added).

HUMBOLDT

The special historical importance of the work of Wilhelm von Humboldt (1767–1835) lies in the fact that it incorporates the transition from the eighteenth-century philosophy of language to the nineteenth-century science of linguistics. It does so not only in respect of the philosophical doctrines presented in it but also because Humboldt coupled those doctrines with empirical investigations of the sort he considered to be demanded by his philosophy of language.

His most important work—*Ueber die Kawi-Sprache auf der Insel Jawa* (published 1836–1839)—begins with the lengthy philosophical essay “Ueber die Verschiedenheit des menschlichen Sprachbaues und ihren Einfluss auf die geistige Entwicklung des Menschengeschlechts.” In it he developed his single most influential and original notion—that language is to be viewed not as a finished product but as a continuous process (*Sie selbst ist kein Werk, ergon, sondern eine Tätigkeit, energie*), as the totality of instances of speech (or of the understanding of speech). Written words constitute language only when they are read and to the extent to which they are understood (*Gesammelte Schriften*, edited by A. Leitzmann, 7[No. 1].46 ff.). The rules of syntax and the individual words of a language are, then, the products of analysis, having real existence only insofar as they are embodied in instances of actual speech. Thus, as Destutt de Tracy and Bentham had observed from other points of view, “we cannot possibly conceive of language as beginning with the designation of objects by words and thence proceeding to their organization. In reality, discourse is not composed from words that preceded it. On the contrary, the words issued from the totality of discourse” (7[No. 1].72 ff.; cf. 7[No. 1].143).

The essential role played by language in fixing and organizing thoughts had been recognized long before Humboldt, but he extended that recognition into the bold new doctrine that language activity was the medium of contact between the mind and reality. “Man lives with the world about him principally, indeed ... exclusively, as language presents it to him.” Humboldt felt that this conception of language held the solution to the post-Kantian problems regarding subjectivity and objectivity.

In speech the energy of the mind breaks a path through the lips, but its product returns through our own ears. The idea is [thus] translated into true objectivity without being withdrawn from subjectivity. Only language can do this.... [Moreover,] just as the particular sound mediates between the object and the man, so the whole language mediates between him and the nature that works upon him from within and without. He surrounds himself with a world of sounds in order to assimilate the world of objects. (7[No. 1]. 55ff.)

Somewhat as Hamann had done, Humboldt thus believed that philosophy reduced to the philosophy of language, and that he had “discovered the art of using language as a vehicle by which to explore the heights, the depths, and the diversity of the whole world” (letter to Wolfe, 1805).

The differences among natural languages were philosophically as well as scientifically important in Humboldt’s view, and he was opposed to the prevailing eighteenth-century type of universal grammar, which achieved its universality at the expense of linguistic differences that happened not to fit the grammatical schema adopted by the grammarian-philosopher. He proposed instead, and provided examples of, a genuinely comparative grammar, insisting that the comparative grammarian avoid adopting the grammar of Latin or of his native language as the schema within which to organize the forms of other languages (“Ueber das Entstehen der grammatischen Formen und ihren Einfluss auf die Ideenentwicklung,” in *Gesammelte Schriften* 4.285 ff.). Each natural language, he believed, was characterized by its own “inner form,” expressive of the psyche of the nation within which it had developed and which it bound together. The distinctive inner form manifested itself in the root words as well as in the patterns of word combinations peculiar to the language. This doctrine, which powerfully influenced the development of linguistics, was in Humboldt’s presentation of it little more than a consequence of the traditional semantic doctrine that speech reflected not objects but man’s view of objects, coupled with the novel romanticist conviction that the reactions of men to the world around them were not everywhere the same. Not only were the grammatical differences among languages to be respected and studied in their own right, but the separate vocabularies were also to be reexamined with a view to discovering not interlinguistic synonymy (which, strictly speaking, was illusory) but the nuances of mean-

ing that gave expression to different world views (7[No. 1].59 ff.; 89ff.; 190ff.).

Humboldt’s immediate influence was not on philosophers but on other founders of the science of linguistics, particularly on Franz Bopp (1791–1867). What influence his work eventually had on philosophy of language, at any rate outside Germany, seems to have been transmitted indirectly through the work of nineteenth- and twentieth-century linguists.

JOHNSON

Alexander Bryan Johnson (1786–1867), the earliest American philosopher of language, was an isolated figure in the history of semantics. Locke and the Scottish common-sense philosophers strongly influenced his work, and he had learned something of the *idéologues* through Dugald Stewart’s account of them. He seems, however, to have had little or no knowledge of his other predecessors and contemporaries. Johnson’s work on language, published in three successive versions and under various titles in 1828, 1836, and 1854, went unnoticed for a hundred years and has had no appreciable influence since its republication during the 1940s. As the circumstances of his work would lead one to expect, it was unusual for its time both in its insights and in its mistakes.

The mistake that led to most of the others and to some of his principal insights as well occurred in his account of the semantics of words, in which he identified the signification(s) of a word with the thing(s) to which the word is applied. “Every word,” he argued, “is a sound, which had no signification before it was employed to name some phenomenon.” Consequently, “words have no inherent signification, but as many meanings as they possess applications to different phenomena. *The phenomenon to which a word refers, constitutes in every case, the signification of the word*” (*Treatise on Language*, Lectures VI and V; italics added).

The phenomena available as referents (or meanings) were exhaustively divided by Johnson into “sights, sounds, tastes, feels, smells, internal feelings, thoughts, and words” (Lecture XI). The word *table*, for example, signifies both a sight and a feel, “two distinct existences” bearing a single name. In this way “language implies a oneness to which nature conforms not in all cases,” and men are prone to “make language the expositor of nature, instead of making nature the expositor of language” (Lecture III). Johnson made this common human failing his constant theme and provided several examples of philosophical and scientific difficulties that he felt were obviated by exposing a confusion of this sort as their source.

Philosophers, he suggested, might append to every “nominal unit that aggregates objects generically different” a capital letter—for instance, *S*, sight; *F*, feel—indicative of the phenomenon signified on each occasion. By that means David Hume, for example, might be seen to be announcing an “unconscious quibble,” when he says, “The table (*S*) which we see, seems to diminish (*S*) as we recede from it, but the real table (*F*) suffers no diminution (*F*).” The whole zest of the proposition consists in the sensible duality of each of the nominal units table and diminution.... We play bo-peep with words, by neglecting to discriminate the intellectually conceived oneness of diminution, and its physical duality” (*The Meaning of Words*, pp. 89–92).

In his account of the semantics of propositions Johnson remained faithful to the identification of meaning and referent with disastrous results, the most obvious of which was the confusion of meaningfulness (or meaninglessness) with truth (or falsity). “No proposition,” he held, “can signify more than the particulars to which it refers” (Lecture VIII). He saw that one difficulty with this doctrine was that under it “the proposition that all men must die seems equivalent only to the proposition that all men have died.” In his attempt to preserve the “universal application” of such general propositions, he adopted the indirect criterion of the failure of their negations to refer to any sensible particular. Thus “the proposition that all men will die, possesses a universal application for the reason that to say, some men will not die, *refers to no sensible particulars, and hence is insignificant*” (Lecture IX; italics added).

It was, however, this same approach to the semantics of propositions that led Johnson to develop and make critical use of a verifiability criterion of meaningfulness. Chemists, he remarked, had an indisputable right to “say simply that they can produce hydrogen gas, and oxygen, from water, and vice versa,” but what they say instead is “that water is nothing but a combination of these gases. The assertion is true, *so long as it means [merely] the phenomena to which it refers*; but it produces wonder, because we suppose it has a meaning beyond the phenomena” (Lecture VII; italics added). Similarly, “if you inquire of an astronomer whether the earth is a sphere, he will desire you to notice what he terms the earth’s shadow in an eclipse of the moon, the gradual disappearance of a ship as it recedes from the shore, &c. After hearing all that he can adduce in proof of the earth’s sphericity, *consider the proposition [‘the earth is a sphere’] significant of these proofs. If you deem it significant beyond them, you are deceived by the forms of language*” (Lecture VIII; italics

added). In his verifiability criterion of meaningfulness and in his related discrimination of significant and insignificant questions (Lectures XIX ff.), Johnson anticipated some of the fundamental semantic principles of the pragmatists and positivists.

MILL

Many of the remarkable developments in semantics in the late nineteenth and early twentieth centuries took place under the influence of or in reaction against the doctrines of John Stuart Mill (1806–1873). He presented his “philosophy of language” (a designation he seems to have made current) in Book I and Chapters III–VI of Book IV of *A System of Logic* (1843), acknowledging the influence of the medieval logicians and Hobbes in particular, but also of Locke, Dugald Stewart, and others in the tradition of British empiricism. Like most of his empiricist predecessors in France and England, Mill believed that a philosophical inquiry into language had a high therapeutic value for philosophy itself, viewing metaphysics as “that fertile field of delusion propagated by language” (1.7.5).

By way of explaining his return to the practice of associating semantical inquiries with logic, Mill argued that since “language is an instrument of thought,” not only in the reasoning process proper but in the antecedent operations of classification and definition, “logic ... includes, therefore, the operation of Naming” (introduction, Sec. 7). It is not clear whether Mill intended to *identify* the ratiocinative use of language with naming or to claim that all language *stems from* the operation of naming, but he did revert to the tradition of considering “names” as the elements of his semantic theory. And since he took it to be obvious that “a proposition ... is formed by putting together two names” (1.1.2), it seemed equally obvious that “the import of words [or names] should be the earliest subject of the logician’s consideration: because without it he cannot examine into the import of propositions” (1.1.1).

NAMES. In his account of the import of names, Mill began by taking the unusual tack of defending “the common usage” against the view of “some metaphysicians,” arguing that words are “names of things themselves, and not merely of our ideas of things.” (Although there are passages in Hobbes and Locke, for example, that can be interpreted as expressions of that view, neither they nor, it seems likely, anyone else held quite the view Mill was criticizing.) “It seems proper,” Mill claimed, “to consider a word as the *name* of that ... concerning which, when we

employ the word, we intend to give information.” When, however, “I use a name for the purpose of expressing a belief, it is a belief concerning the thing itself, not concerning my idea of it,” even when the belief in question is one concerning some idea of mine (1.2.1).

A name, in Mill’s adaptation of scholastic terminology, was said to *denote*, individually and collectively, the things of which it was the name, “the things of which it can be predicated.” But, as Mill observed, “by learning what things it is a name of, we do not learn the *meaning* of the name” (1.2.5). A name happens “to fit” a given thing “because of a certain *fact*. ... If we want to know what the fact is, we shall find the clue to it in the *connotation*” of the name (1.5.2). The connotation of the name is the “attribute” or set of attributes possession of which by a given thing is the fact in virtue of which the name fits the thing, and “the *meaning* of all names, except proper names [which have no meaning] and that portion of the class of abstract names which are not connotative [such as ‘squareness,’ which *denotes* a single attribute], resides in the connotation” (1.5.2). Mill recognized the connection of this distinction with the doctrine of denominatives (see the discussion of Anselm above), and in a note to 1.5.4 he indicated its relations to Hamilton’s intension-extension distinction (see below).

CONNOTATION AND DENOTATION. Mill believed that the connotation-denotation distinction was “one of those which go deepest into the nature of language” (1.2.5). He made considerable use of it himself, and it played an important part in philosophical discussions for at least seventy-five years afterward. It is, however, a notoriously unclear distinction, especially in Mill’s own treatment of it. With regard to denotation, for example, he claimed that a “concrete general name” such as “man” denotes Socrates—that is, is a name of, is predicable of that individual—but he claimed also that it denotes *the class of which that individual is a member, which (at best) introduces a crucial ambiguity into the notion of denotation.* With regard to connotation, the most serious difficulty centers on the notion of “attributes,” which Mill suggested at one point was to be identified with what medieval logicians meant by “forms” (1.2.5n). In an evidently more careful account he declared that “the meaning of any general name is some outward or inward phenomenon, consisting, in the last resort, of feelings; and these feelings, if their continuity is for an instant broken, are no longer the same feelings, in the sense of individual identity.

What, then, is the common something which gives a meaning to the general name? Mr. [Herbert] Spencer can only say, it is the similarity of the feelings: and I rejoin, the attribute is precisely that similarity.... The general term *man* does not connote the sensations derived once from one man.... It connotes the general type of the sensations derived from all men, and the power ... of producing sensations of that type” (2.2.4n). The only plausible interpretation of this doctrine seems to bring it very close to Hobbes’s (or Locke’s) actual account of words as signs of our ideas (despite Mill’s attack on its weakest version: Words are *names* of our ideas), for in the end Mill’s semantics of words appears to be founded on the familiar view that words are signs of extramental entities (denotation) only in virtue of being signs of mental entities of some sort (connotation). Mill surely would have recoiled at the suggestion that his doctrine of the connoted attribute as a “general type” of sensations committed him to an acceptance of extramental metaphysical entities.

After a detailed, ingenious investigation of the semantics of many-worded connotative concrete individual names (1.2.5), frequently discussed by his successors, Mill turned to the semantics of propositions. His account of the meaning of names and his view that the meaning of a proposition is a function of the meanings of the names that serve as its terms led naturally to his view that “when ... we are analyzing the meaning of any proposition in which the predicate and the subject, or either of them, are connotative names, it is to the *connotation* of those terms that we must exclusively look, and not to what they *denote*.” The view of Hobbes—that the predicate term is to be considered a name of whatever the subject term names—“is a mere consequence of the conjunction between the two attributes,” the connotations of the two terms, and is adequate only in case both terms are nonconnotative names (1.5.2).

Thus, “all men are mortal” asserts that “the latter set of attributes *constantly accompany* the former set.” And on the basis of the account of attributes introduced above, “we may add one more step to complete the analysis. The proposition which asserts that one attribute always accompanies another attribute, really asserts thereby no other thing than this, that one phenomenon always accompanies another phenomenon; in so much that where we find the latter, we have assurance of the existence of the former.” He was, however, careful to note that “the connotation of the word *mortal* goes no farther than to the occurrence of the phenomenon at some time or other” (1.5.4).

When he came to discuss “real” (as opposed to “verbal”) propositions, however, Mill disclosed that with respect to real propositions the account just cited was only one of “two formulas” in which “their import may be conveniently expressed.” The account in terms of companion sets of attributes is suited to the view of real propositions “as portions of speculative truth.” But they may be viewed also “as memoranda for practical use,” and Mill’s consideration of them in this light prefigured some elements of pragmatist theories of meaning. “The practical use of a proposition is, to apprise or remind us what we have to expect in any individual case which comes in the assertion contained in the proposition. In reference to this purpose, the proposition, All men are mortal, means that the attributes of man are *evidence of*, are a *mark of*, mortality; ... that where the former are we ... [should] expect to find the latter.” The two formulas for expressing the import of real propositions are, Mill maintained, “at bottom equivalent; but the one points the attention more directly to what a proposition means, the latter to the manner in which it is to be used” (1.6.5).

Mill agreed with the majority of his philosophical contemporaries in deploring attempts to devise a formalized language for philosophy and suggesting that philosophers reform the natural languages for their uses. He was in a minority, however, in urging philosophers to have a healthy respect for natural languages. One of the “inherent and most valuable properties” of a natural language is “that of being the conservator of ancient experience”—“Language is the depository of the accumulated body of experience to which all former ages have contributed their part, and which is the inheritance of all yet to come.” Consequently, “it may be good to alter the meaning of a word, but it is bad to let any part of the meaning drop” (4.4.6). Mill was emphatic about the special respect with which words of uncertain connotation were to be treated, and he laid down as a principle for the guidance of philosophers that “the meaning of a term actually in use is not an arbitrary quantity to be fixed, but an unknown quantity to be sought” (4.4.3). The attitude toward natural languages enjoined on philosophers by Mill was in part the attitude adopted by J. L. Austin and other twentieth-century philosophers of ordinary language.

PEIRCE AND THE PRAGMATISTS

In a tradition stemming from Locke, Charles Sanders Peirce (1839–1914) characterized logic “in its general sense” as “*semiotic* (σημειωτική), the quasi-necessary, or formal, doctrine of signs” (*Collected Papers* 2.227) and went much further than anyone before him had tried to

go toward the development of a completely general theory of signs. (Insofar as Peirce’s semiotic deals with non-linguistic signs, it lies outside the scope of this article, but his elaborate, varying terminology makes it difficult to present a single standard version of even that portion of the theory which is directly relevant to his treatment of linguistic meaning.)

Peirce seems sometimes to have thought of semiotic as a generalized version of the medieval trivium, describing its three branches as “pure grammar,” “logic proper,” and “pure rhetoric” (2.228–229). The first branch was to investigate the necessary conditions of meaningfulness, the second was to investigate the necessary conditions of truth, and the third was “to ascertain the laws by which in every scientific intelligence one sign gives birth to another, and especially one thought brings forth another” (2.229). These branches, with their subject matter somewhat differently described, were to become well known in twentieth-century philosophy under the designations “syntactics,” “semantics,” and “pragmatics” respectively—designations introduced by Charles W. Morris (*Foundations of the Theory of Signs*, 1938) and used extensively by Rudolf Carnap and others.

“Semiosis” was Peirce’s name for an instance of signification, which he described as involving three principal elements: the *sign*, “something which stands to somebody for something in some respect or capacity” (its “ground”); the *object*, that for which the sign stands; and the *interpretant*, another sign, equivalent to or “more developed” than the original sign and caused by the original sign in the mind of its interpreter (2.228). The notion of the interpretant is the distinctive element in Peirce’s general account of signification and the one that played the central role in his pragmatism (or “pragmaticism”), which he often described as consisting entirely in “a method for ascertaining the real meaning of any concept, doctrine, proposition, word, or other sign” (5.6).

Some of Peirce’s predecessors had already suggested that the meaning of a word could be determined only on a given occasion of its occurrence within a propositional context, but in Peirce’s the traditional primacy of the semantics of words over the semantics of propositions was so thoroughly overturned that his theory of linguistic meaning is almost exclusively a theory regarding the meaning of whole propositions. According to that theory, a proposition, like every other sign, has an object—some state of affairs, factual or otherwise. The *meaning* of a proposition, however, he identified not with its object but with one particular kind of effect of the proposition on

an interpreter, namely, its “*logical*” (as opposed to “emotional” or “energetic”) *interpretant* (5.476).

Peirce’s definitive account of the logical interpretant appeared in the 1905 paper “What Pragmatism Is” (5.411–434), in which he attempted as well to explain the distinctive and often misinterpreted “futuristic” aspect of pragmatist meaning theory.

The rational meaning of every proposition lies in the future. How so? The meaning of a proposition [that is, its logical interpretant] is itself a proposition. Indeed, it is no other than the very proposition of which it is the meaning; it is a translation of it. But of the myriads of forms into which a proposition may be translated, what is that one which is to be called its very meaning? It is, according to the pragmatist, that form in which the proposition becomes applicable to human conduct, ... that form which is most directly applicable to self-control under every situation and to every purpose. This is why he locates the meaning in future time; for future conduct is the only conduct that is subject to self-control.

The only form of the proposition that would satisfy all these conditions was “the general description of all the experimental phenomena which the assertion of the proposition virtually predicts. For an experimental phenomenon is the fact asserted by the proposition that action of a certain description will have a certain kind of experimental result; and experimental results are the only results that can affect human conduct.” Thus, as Peirce finally conceived of it, the meaning of a proposition is evidently to be explicated in the form of a true conditional with the original proposition as antecedent and, as its consequent, a conjunction of propositions constituting “the general description of all the experimental phenomena which the assertion of the [original] proposition virtually predicts.”

Among the more striking problems in this account are (1) the difficulty of applying it to propositions other than those which occur within the context of an experimental science and (2) the fact that the meaning of a proposition is said to consist in other propositions, the meanings of which are presumably explicable in the same fashion, *ad infinitum*. Peirce was aware of both these problems. His response to (1) was generally to minimize the differences between the context of an experimental science and other contexts within which propositions occur, although he did occasionally, especially in his later writings, acknowledge the perhaps insuperable difficul-

ties in employing this as a completely general theory of linguistic meaning. With regard to (2) Peirce was at first inclined to claim that a proposition (or any other sign) was, indeed, imperfectly significant if the series of its interpretants was finite (“Sign,” in Baldwin’s *Dictionary*).

Later, however, the notion of “the *ultimate* logical interpretant” was introduced. “The real and living logical conclusion” of the series of logical interpretants is an expectation (on the interpreter’s part) of certain phenomena “virtually” predicted by the assertion of the original proposition. This expectation Peirce frequently referred to as “habit.” “The deliberately formed, self-analyzing habit—self-analyzing because formed by aid of analysis of the exercises that nourished it—is the living definition, the veritable and final logical interpretant” (5.491; cf. 5.486). Habit, which Peirce sometimes described as a “readiness to act in a certain way under certain circumstances and when actuated by a given motive,” was not itself a sign and so stood in no need of interpretants of its own.

It was on this very point that Peirce thought his own doctrine differed from that of William James (1842–1910). “In the first place,” he wrote, “there is the pragmatism of James, whose definition differs from mine only in that he does not restrict the ‘meaning,’ that is, the ultimate logical interpretant, as I do, to a habit, but allows percepts, that is, complex feelings endowed with compulsiveness to be such” (5.494). James’s own definition of “pragmatism” in Baldwin’s *Dictionary* identified it as “the doctrine that *the whole meaning* of a conception *expresses itself in practical consequences* either in the shape of conduct to be recommended or in that of experiences to be expected, if the conception be true” (italics added), but in doing so he evidently believed he was promulgating “Peirce’s principle ... that *the effective meaning* of any philosophic proposition can always be *brought down to some particular consequence*, in our *future practical experience*, whether active or passive” (*Collected Essays and Reviews*, edited by R. B. Perry, p. 412; italics added). James’s conception of pragmatism as a theory of meaning (and of truth) was, however, unquestionably broader and less carefully qualified than Peirce’s and may fairly accurately be summarized in his own characteristic observation that concepts and propositions “have, indeed, no meaning and no reality if they have no use. But if they have any use they have that amount of meaning. And the meaning will be true if the use squares well with life’s other uses” (*Pragmatism*, p. 273).

Pragmatism first became generally known in the form given it by James and in the still wider “humanism”

of F. C. S. Schiller, and it was in those forms that it was subjected to intense criticism at the beginning of the twentieth century by F. H. Bradley and G. E. Moore, among others. Peirce's more intricate and interesting theory of meaning was not really considered in its own right until some years afterward, perhaps beginning with the publication of C. K. Ogden and I. A. Richards's very influential *The Meaning of Meaning* in 1923, in which some ten pages were devoted to an exposition of Peirce's semiotic.

At the same time a pragmatist theory of meaning more complex and no less broad than James's was being developed in the "instrumentalism" of John Dewey (1859–1952). Dewey discussed meaning of every imaginable sort and in countless contexts, with the result that it is difficult to elicit from his many writings a genuinely representative doctrine specifically of linguistic meaning. Perhaps the least misleading single source is Chapter 5 of his *Experience and Nature*, first published in 1925. His position there was as follows:

The sound, gesture, or written mark which is involved in language is a particular existence. But as such it is not a *word*, and it does not become a word by declaring a mental existence; it becomes a word by gaining meaning; and it gains meaning when its use establishes a genuine community of action.... Language and its consequences are characters taken on by natural interaction and natural conjunction in specified conditions of organization.... Language is specifically a mode of interaction of at least two beings, a speaker and a hearer; it presupposes an organized group to which these creatures belong, and from whom they have acquired their habits of speech. It is therefore a relationship, not a particularity.... The meaning of signs moreover always includes something common as between persons and an object. When we attribute meaning to the speaker as *his* intent, we take for granted another person who is to share in the execution of the intent, and also something, independent of the persons concerned, through which the intent is to be realized. Persons and thing must alike serve as means in a common, shared consequence. This community of partaking is meaning.

Even when, as in these passages, Dewey seems to have been considering linguistic meaning specifically, there is a real possibility that his intentions were much broader, for his conception of language was itself considerably

broader than that of most philosophers. He was, for example, prepared to say that "because objects of art are expressive, they are a language. Rather they are many languages. For each art has its own medium and that medium is especially fitted for one kind of communication.... The needs of daily life have given superior practical importance to one mode of communication, that of speech" (*Art as Experience*, 1935, p. 106).

Pragmatist theories of meaning, beginning with Peirce's 1878 paper "How to Make Our Ideas Clear," are alike in little more than their tendency to associate the meaning of a proposition with the conditions of its verification, but in that respect they may be said to have inaugurated twentieth-century developments of empiricist and operationalist theories of meaning.

FREGE

The contributions of Gottlob Frege (1848–1925) to logic, philosophy of mathematics, and semantics were largely unappreciated at the time of their publication, primarily during the last quarter of the nineteenth century. Their influence (direct or indirect) on recent philosophy has been so great, however, that Frege might fairly be characterized as the first twentieth-century philosopher. In his *Begriffsschrift* (1879) he developed "a formalized language of pure thought modeled on the language of arithmetic," which has been recognized as the first really comprehensive system of formal logic. In his other two major works, *Die Grundlagen der Arithmetik* (1884) and *Die Grundgesetze der Arithmetik* (1893–1903), he tried to show "that arithmetic is founded solely upon logic."

Philosophical problems encountered by Frege in those highly technical undertakings were explored by him in several papers that have had a wider influence than his books have had. As the topics of the books might lead one to expect, his philosophical papers are concerned almost exclusively with one or another aspect of systems of signs. Of these papers, the one that has had most effect on the development of semantics is "Ueber Sinn und Bedeutung" (1892, translated in P. T. Geach and Max Black, *Translations from the Philosophical Writings of Gottlob Frege*, 1952), although the doctrine presented in it may prove to be historically less important than the doctrine of "functions" developed in other papers.

There is a broad and not wholly misleading similarity between Frege's distinction of sense (*Sinn*) and reference (*Bedeutung*) and such distinctions as comprehension-extension (Arnauld), intension-extension (Hamilton), connotation-denotation (Mill), depth-breadth (Peirce). It seems possible, however, that Frege

developed his distinction independently; in any case, the details of his doctrine are quite novel. Most important, perhaps, was his discovery of special contexts rendering the application of any such distinction problematic.

SENSE AND REFERENCE. Frege's development of the doctrine of sense and reference began, characteristically, in a consideration of the relation of identity: "=". He noted that " $a = a$ and $a = b$ are obviously statements of different cognitive value," which they would not be if we were to take the relation to hold "between that which the names ' a ' and ' b ' designate" or refer to (Geach and Black, p. 56). Consequently, "it is natural now, to think of there being connected with a sign (name, combination of words, letter), besides that to which the sign refers, which may be called the reference of the sign, also what I should like to call the *sense* of the sign, wherein the mode of presentation is contained.... The reference of 'evening star' would be the same as that of 'morning star,' but not the sense" (p. 57).

Frege first applied his distinction to proper names, by which he meant any "designation of a single object." In keeping with Arnauld's similar distinction but in opposition to Mill's, Frege ascribed sense as well as reference to such designations. "A proper name (word, sign, sign combination, expression) *expresses* its sense, *stands for* or *designates* its reference. By means of a sign we express its sense and designate its reference" (p. 61). The sense of "Aristotle" might, for instance, be taken to be the following: the pupil of Plato and the teacher of Alexander the Great" (p. 58n).

Certain expressions, such as "the least rapidly convergent series," have a sense, he maintained, but no reference at all. "In grasping a sense, one is not certainly assured of a reference" (p. 58). An expression that has a reference "must not be taken as having its ordinary reference" when "standing between quotation marks" (pp. 58–59). Such observations had been made before, but Frege seems to have been the first to try to show what that extraordinary reference might be and, more important, to recognize that many different linguistic contexts affected the reference of expressions included within them, especially indirect discourse and subordinate clauses following such verbs as "hear," "conclude," "perceive," and "know." He claimed, for example, that "in reported speech, words ... have [not their customary but] their *indirect* reference," and that "the indirect reference of a word is ... its customary sense" (p. 59). His account of the effect of such contexts on reference has not been widely accepted, but the problems raised by it have stimulated

the widespread interest of twentieth-century philosophers in such now familiar topics as synonymy, opacity of reference, Leibniz's Law, and what, following Franz Brentano (see below), have come to be called intentional contexts.

Frege was concerned with saying what sort of entities sense and reference were. In the case of a proper name his description of the reference was relatively unproblematic: "a definite object (this word ['object'] taken in the widest range)"—(p. 57)—so wide that " $2 + 2$ " and "4," for example, were two proper names with one and the same "object" as their reference. Regarding the sense of a proper name, he found it easier to say what it was not: "The reference of a proper name is the object itself which we designate by its means; the idea, which we have in that case, is wholly subjective; in between lies the sense, which is indeed no longer subjective like the idea, but is yet not the object itself" (p. 60). Thus, there is "an essential [subjective-objective] distinction between the idea and the sign's sense." Frege seems not to have completely depsychologized the notion of the sense of the sign, however, since he suggested that it may be an element in humankind's "common store of thoughts which is transmitted from one generation to another" rather than "a part or a mode of the individual mind" (p. 59).

In Frege's discussion of the sense and reference of declarative sentences, the doctrine of the sense was relatively straightforward while the account of the reference became problematic. A sentence, he held, "contains a thought," and by "a thought" he meant "not the subjective performance of thinking but its objective content, which is capable of being the common property of several thinkers" (p. 62 and note). The two sentences "the morning star is a planet" and "the evening star is a planet" contain different thoughts, as may be seen from the fact that "anybody who did not know that the evening star is the morning star might hold the one thought to be true, the other false. The thought, accordingly, cannot be the reference of the sentence, but must rather be considered its sense" (p. 62). We are content to consider only the sense of sentences as long as we are not concerned to judge of their truth or falsity, but "in every judgment, no matter how trivial, the step from the level of thoughts to the level of reference (the objective) has already been taken" (p. 64). What we seek in judgment is the truth-value of the sentence. "We are therefore driven into accepting the truth-value of a sentence as constituting its reference.... Every declarative sentence concerned with the reference of its words is therefore to be regarded as a proper name,

and its reference, if it has one, is either the True or the False” (p. 63).

As his use of the phrase “driven into accepting” indicates, Frege was well aware that this was a startling doctrine of the semantics of sentences. Much of the remainder of his paper on sense and reference was devoted to considerations that he felt tended to support it, among them Leibniz’s Law; for “what else but the truth-value could be found, that belongs quite generally to every sentence if the reference of its components is relevant, and remains unchanged by substitutions of the kind in question?” (p. 64).

The doctrine that sentences are proper names, whether or not of the True and the False, had an important negative effect in that its rejection by Wittgenstein (see, for instance, *Tractatus* 3.143) and by Bertrand Russell under Wittgenstein’s influence (see, for instance, “Logical Constructions,” Lecture I) helped to shape the course of philosophy of language in the twentieth century.

It is quite likely, however, that Frege’s assimilation of declarative sentences to proper names was not quite so thorough or simple as his presentation of it in “Ueber Sinn und Bedeutung” suggests. Some of his remarks in an earlier paper, “Funktion und Begriff” (1891), at least raise the possibility that he may have denied proper-name status to sentences actually being used in making assertions (rather than considered as examples). In order to make what he took to be the indispensable “separation of the act from the subject-matter of judging” he introduced his assertion sign—“┆”—“so that, e.g., by writing

$$\vdash 2 + 3 = 5$$

we assert that $2 + 3$ equals 5. Thus here we are *not just writing down a truth-value*, as in

$$2 + 3 = 5,$$

but also at the same time *saying that it is the True*.” And in a note to this passage he maintained that “‘┆ $2 + 3 = 5$ ’ does not *designate* [that is, refer to] anything; it *asserts something*” (p. 34; italics added).

MAUTHNER

Of the several late nineteenth-century philosophers writing in German whose work centered on a concern with language, the most unusual was Fritz Mauthner (1849–1923). His principal work, *Beiträge zu einer Kritik der Sprache*, fills three large volumes and went through three editions, the first in 1901–1902. In his thoroughgo-

ing attempt to transform all philosophy into philosophy of language, in his criticisms of Kant, and in his penchant for paradox he resembled Hamann, whom he admired, and also, to some extent, Humboldt. He seems, however, to have been most powerfully influenced by the positivism of Ernst Mach and especially by Hume’s skepticism, adopting as his philosophical watchword “Back to Hume!”

Part of what Mauthner meant by that is apparent in the epistemological doctrine on which he founded his critique of language: “Our memory [with which he identified our knowledge] contains nothing but what our poor fortuitous senses [*Zufallsinne*] have presented to it” (*Beiträge* 3.536). By calling our senses “fortuitous” he was calling attention to the fact that if we had been otherwise equipped with senses, we might have framed a very different view of the world. Language, however, depicts not the world but a world view. Therefore, any attempt to infer propositions regarding reality from facts of language is a form of “word-superstition.”

Moreover, each man’s individual senses present a world view unique in certain ultimately undeterminable respects, and so communication by means of language, even if it purports to be no more than an exchange of views, is fundamentally illusory. “No man knows the others.... With respect to the simplest concepts we do not know of one another whether we have the same representation associated with one and the same word.”

From such avowedly Lockean observations Mauthner drew the typically paradoxical conclusion that “by means of language men have made it forever impossible to get to know one another” (1.54). Thus he characterized language as “nothing other than just the community or the mutuality of world-views.” It is not a tool for the communication or acquisition of knowledge; indeed, it is not a tool or an object of any sort but merely a practice, a use. And “because it is no object of use but use itself, it perishes without use” (1.24). But of all Mauthner’s many characterizations of language the one most suggestive of distinctively twentieth-century attitudes is this: “Language is merely an apparent value [*Scheinwert*], like a rule of a game [*Spielregel*], which becomes more binding as more players submit to it, but which neither alters nor comes into contact with [*begreifen*] the world of reality” (1.25).

Philosophy, in Mauthner’s view, had to become a critique of language if it was to be anything at all, and in that guise its principal function was to be therapeutic. “Philosophy ... cannot wish to be anything more than critical attention to language. Philosophy can do no more with

respect to the organism of language or of the human spirit than can a physician with respect to the physiological organism. It can attentively observe and designate the developments with names" (1.657). "If I want to ascend into the critique of language, which is at present the most important undertaking of thinking mankind, I must do away with language behind me and before me and in me, step by step—I must break in pieces each rung of the ladder as I tread on it" (1.1–2). It comes as no surprise to learn that the end of this therapeutic process was to be silence, the silence of mystical contemplation.

In the course of the long process, however, Mauthner found occasion to make many insightful observations on traditional problems of the philosophy of language. As several of his contemporaries and immediate predecessors had done, he recognized not the word but the sentence (*Satz*) as the unit of meaningfulness and described the meaning of the word as a function of its use in a given sentence. Another position that was not new but to which he gave an especially forceful presentation was the rejection of the view "that because there is a word, it must be a word *for* something; that because a word exists there must exist something real corresponding to that word." This form of word superstition he regarded as "mental weakness" (2nd ed., 1.159).

It is probably only coincidence, but the name theory of linguistic meaning against which Mauthner inveighed bears a strong resemblance in some respects to the theories of Alexius Meinong and Edmund Husserl then being published and to the early views of Russell and Wittgenstein. Mauthner also opposed efforts at universal grammar (such as some of Brentano's followers were then engaged in) and mathematical logic, maintaining that all formalization of language obliterated or obscured far more than it clarified. Thus, he noted that "if someone says 'cheese is cheese' ... this utterance is *not* an instance of the general formula 'A = A'" (3.366), a formula "so empty that outside logic it must arouse the suspicion of insanity" (*Wörterbuch der Philosophie*, article "A = A").

Perhaps more than any other philosopher of language Mauthner had an appreciation of the history of the subject; at one time, in fact, he planned a fourth volume of his *Beiträge* that was to present the approach to the critique of language throughout the history of philosophy. Even as it stands, however, his work is filled with references to his predecessors and evaluations of their work from the viewpoint of the critique of language. Aristotle, for example, comes off badly, but Locke ranks very high. Indeed, Mauthner took "the English" to task for abandoning the work of Locke, for failing to see that "the con-

tent of their famous 'understanding' is simply the dictionary and grammar of human language" (*Beiträge* 3.535).

Mauthner's own effect on the history of the philosophy of language is still difficult to assess. Wittgenstein certainly knew of his work (see, for instance, *Tractatus* 4.0031). Whether or not Wittgenstein's turn in the direction of some of Mauthner's doctrines in *Philosophical Investigations* was coincidence or derived in part from Mauthner's influence remains an open question.

HUSSERL AND MEINONG

The students of Franz Brentano (1838–1917), among whom were Husserl, Meinong, Anton Marty, and Kazimierz Twardowski, were alike at least in taking Brentano's concept of intentionality as a point of departure in their own philosophizing. Brentano had introduced intentionality in his *Psychologie vom empirischen Standpunkt* (1874) as the differentia of "mental states," a characteristic "which the schoolmen of the middle ages called the intentional (or mental) inexistence of an object and which we ... describe as *the relation to a content*, or *the direction to an object* (by which we need not understand a reality), or an *immanent objectivity*. Every mental state possesses in itself something that serves as an object, although not all possess their objects in the same way" (*Psychologie* 2.1.5; italics added).

The "intending" of an object by a mental state, the "directedness" of a mental state, bears a close enough resemblance to what is called significance in other contexts that much of what Brentano and his followers had to say in working out their central doctrine of intentionality has some relevance to semantics, broadly conceived. More specifically, the notion of intentionality underlies the considerable discussion in semantics of "intentional contexts," produced as a result of the ordinary use of such "intentional words" as "believe," "want," and "ascribe." For present purposes, however, our attention is confined to what Brentano's two best-known students, Husserl and Meinong, had to say expressly about language and linguistic meaning. The doctrines of both men passed through several stages of development and contain many complexities, only a few of which can be noted here.

The philosophy of language of Edmund Husserl (1859–1938) was developed at various places in his work but is concentrated in the first and fourth essays in his *Logische Untersuchungen* (1900–1901; rev. ed., 1913–1921). The first, titled "Expression and Meaning" (2.23–105), was designed partly as a general preparation for intensive work in phenomenology as conceived by

Husserl. It opens with an investigation of signs in general and proceeds to the consideration of expressions, signs that may be said to have meanings (*Bedeutungen*) and not merely to indicate something. The three ingredients of meaningfulness, or “the meaning-situation” are (1) a “meaning-endowing act,” or “meaning-intention” on the part of the producer of the expression, which may be associated with a “meaning-fulfilling act” on the part of an interpreter of the expression; (2) the *content* of these acts, or the *meaning* of the expression; (3) the *object* of these acts, or, in Husserl’s broader terminology, the *objectivity* that is meant by the expression. To talk about what is expressed by a given expression may be to talk about any one of these ingredients. (To some extent Husserl avoided the usual sort of technical distinctions among semantical relations, specifically rejecting Frege’s sense-reference distinction as a violation of the ordinary use of the words *Sinn* and *Bedeutung*, words which Husserl used interchangeably [2.53].)

Somewhat more precisely, an expression used in ordinary circumstances for purposes of communication may be described as “manifesting” the psychical experience of its producer—that is, the meaning-endowing act—which is a necessary condition of its status as an expression. This manifesting function of an expression would, however, be lacking in the case of an expression used in an unoverheard monologue. The manifesting and the more strictly expressing functions differ also in that, for example, the expression “the three altitudes of a triangle intersect in a point” manifests a distinct mental state or act each time it is used in ordinary circumstances for purposes of communication, although what it expresses, in the stricter sense, remains the same on all occasions of such use.

Some of Husserl’s main points in “Expression and Meaning” are summarized in sections dealing with “equivocations” associated with discussions of meaning and meaninglessness (2.52–61). “A meaningless expression is, properly speaking, not an expression at all.” Thus “green is or” (Husserl’s example) only gives the appearance of an expression (2.54). Meaningfulness, however, entails reference (*Beziehung*) to an object, regardless of whether that object exists or is “fictive.” “Consequently, to use an expression with sense and to refer to an object (to present an object) are one and the same.” Nevertheless, Husserl was careful to point out, the object of an expression is not to be confused with its meaning (2.54). As a result, “objectlessness” of an expression is not “meaninglessness” (where “objectlessness” indicates only the lack of a real object). Neither the name “golden mountain” nor

the name “round square” is meaningless, although both are objectless, the second one necessarily so (2.55). After a rather obscure passage (2.56–57) in which Husserl was evidently criticizing (without mentioning) pragmatism for identifying meaning with meaning-fulfilling acts, he devoted an entire section to the criticism of Mill’s doctrine of connotation and denotation, with particular attention to Mill’s view of “non-connotative names” as meaningless. A proper name, Husserl objected, is not a mere sign but an expression. It can, like any other expression, function as a mere sign—for instance, in a signature—but it ordinarily does much more. He felt that if Mill’s distinction between what a name denotes and what it connotes were carefully separated from the merely related distinction between what a name names and what it means, some of the confusion in Mill’s doctrine would be dissipated (2.57–61).

In his fourth Logical Investigation, “The Distinction of Independent and Dependent Meanings and the Idea of a Pure Grammar” (2.294–342), Husserl pursued the analysis of meaning undertaken in the earlier treatise. Of most historical interest is his attempted refurbishing of the Enlightenment project of a universal grammar, an enterprise furthered by Anton Marty (1847–1914), another of Brentano’s students, in his *Grundlegung der allgemeinen Grammatik und Sprachphilosophie* (1908). In his treatise Husserl developed a notion of “pure logic” as “the pure formal theory of *meanings*” and insisted that we could not understand the functioning of even our own language if we did not first construct a “pure-logical grammar,” the subject matter of which would be the “ideal form” of language. At a later stage of his career, however, Husserl abandoned this “ideal-language” approach to considerations of semantics and syntax and urged the return to living history and actual speech—the return to the *Lebenswelt*—for the materials of philosophy.

Husserl’s influence in all respects has been felt more strongly in Europe than in England and America. Some of his work in philosophy of language has been investigated and developed further by, among others, Maurice Merleau-Ponty.

Alexius Meinong (1853–1920) developed his theory of linguistic meaning as an integral part of the “theory of objects” in which he worked out his version of the doctrine of intentionality. His most complete presentation of it may be found in his *Ueber Annahmen* (1902; rev. ed., 1910).

Meinong began, in the traditional way, by developing a semantics of words. His assimilation of it to his theory of objects gave rise to no particularly novel features.

“Whoever happens to pronounce the word ‘sun,’ he declared, “normally gives *expression* [*Ausdruck*] thereby, whether or not he wishes to do so, that a definite presentation—it may be a presentation of perception or one of imagination—is taking place within him. What kind of presentation it is is determined principally on the basis of what is presented in it—i.e., its object—and this object is precisely that which the word ‘sun’ *refers to* [*bedeutet*]” (*Ueber Annahmen*, pp. 19–20; italics added). He summed up his account of the “expression” and “reference” of words (which he presented explicitly as opposed to Husserl’s doctrine of *Ausdruck* and *Bedeutung*) by saying that “a word always ‘refers to’ the object of the presentation that it ‘expresses’ and, conversely, expresses the presentation of the object that it refers to” (p. 20). (The obvious similarities to Frege’s doctrine of sense and reference, even as to the same unusual use of *bedeuten*, may be coincidental. There are, of course, clear differences as well, especially as regards Frege’s treatment of “sense” and Meinong’s treatment of “expression.”) Meinong concluded his rather brief account of the meaning of words by refining his original distinction to the point of recognizing a “secondary” as well as the “primary” expression and reference described above (pp. 20–23).

He then undertook to apply his “antithesis of expression and reference” to the semantics of sentences, and he first applied it in an effort to provide a more satisfactory criterion of sentencehood than that provided by traditional grammar. The phrase “the blue sky” and the sentence “the sky is blue” have, he maintained, one and the same object as their reference. If, however, “I say ‘the sky is blue,’ I thereby *express* an opinion [*Meinung*], a judgment, that can in no way be gathered from the words ‘the blue sky’” (p. 25; italics added). The phrase expresses the kind of experience described by Meinong as the pure presentation or idea, the *Vorstellung* proper, while the sentence expresses a different fundamental kind of experience, the judgment (*Urteil*). The judgment differs from the pure presentation giving rise to it in two respects that might be described as “intentional”—conviction and a determinate position as regards affirmation and negation (p. 2). Sentences, he claimed, might also be used to express “assumptions” (*Annahmen*), which, because they have to be either affirmative or negative assumptions, share the second defining characteristic of judgments but lack the first, conviction (p. 4).

Meinong’s most important contribution to semantics, partly because of its effect on the development of Russell’s theory of descriptions, was his doctrine of “objectives,” particularly in his application of it in the

treatment of negative sentences, which he recognized to be crucial cases for his doctrine. Suppose that a magistrate judges that on a given occasion there was no disturbance of the peace. On the Brentano-Meinong view of mental states, there must be an object of that judgment. Putting it another way, there must be a reference for the sentence “there has been no disturbance of the peace,” which expresses the magistrate’s judgment. It cannot be the disturbance of the peace on the occasion in question, for, by the hypothesis, there is no such object. According to Meinong it can, however, be “the non-existence of a disturbance of the peace” or “that there has been no disturbance of the peace.” Meinong held that it makes no sense to say that that nonexistence *exists*, but we may say that “it is the case.” This entity, the being of which is being the case, is the “objective” to which the sentence refers. The objective *may* be a fact—if, for example, it is a fact that there has been no disturbance of the peace—but false judgments also have their objectives (2nd ed., p. 43). That regarding which the judgment is made—a disturbance of the peace—is the object (proper) of the judgment; what is judged in it—that there has been no disturbance of the peace—is its objective (2nd ed., p. 52).

The objectives of negative sentences and the objects of denials of existence, such as “a *perpetuum mobile* does not exist,” “must have properties, and even characteristic properties, for without such the belief in non-existence can have neither sense nor justification; but the possession of properties is as much as to say a manner of being [*Sosein*],” which of course is not to be confused with existence. “In this sense ‘there are’ also objects that do not exist, and I have expressed this in a phrase that, while rather barbarous, I am afraid, is hard to improve upon—viz. ‘externality [*Aussersein*] of the pure object’” (p. 79). Meinong believed that he had formulated an important principle in this doctrine, “the principle of the independence of manner of being from existence,” which he illustrated and summarized in the following famous passage: “Not only is the often cited golden mountain golden, but the round square, too, is as surely round as it is square.... To know that there are no round squares, I have to pass judgment on the round square.... Those who like paradoxical expressions can therefore say: there are objects of which it is true that there are no objects of that kind” (*Ueber Gegenstandstheorie*, 1904, pp. 7ff.). Meinong’s influence on the development of semantics is best exhibited in Russell’s series of articles on him in *Mind*, 1899–1907.

Bibliography

There is at present no thorough general study of the history of semantics. Much relevant information may be found, however, in works on the history of logic, particularly in I. M. Bocheński, *A History of Formal Logic*, translated by Ivo Thomas (Notre Dame, IN, 1961); Philotheus Boehner, *Medieval Logic* (Manchester, U.K.: Manchester University Press, 1952); L. M. de Rijk, *Logica Modernorum*, Vol. I (Assen: Van Gorcum, 1962); William and Martha Kneale, *The Development of Logic* (Oxford: Clarendon Press, 1962); Benson Mates, *Stoic Logic* (Berkeley: University of California Press, 1953); E. A. Moody, *The Logic of William of Ockham* (New York and London: Sheed and Ward, 1935), and *Truth and Consequence in Mediaeval Logic* (Amsterdam: North-Holland, 1953); and Carl Prantl, *Geschichte der Logik im Abendlande*, 4 vols. (Leipzig: Hirzel, 1855–1870).

Surveys less thorough than this entry are contained in Ch. 7, "Language," of Janet and Séailles's *History of the Problems of Philosophy*, translated by A. Monahan and edited by H. Jones (New York: Macmillan, 1902), and in Ch. 1, "The Problem of Language in the History of Philosophy," of Vol. I, *Language*, of Ernst Cassirer's *The Philosophy of Symbolic Forms*, translated by R. Manheim (New Haven, CT: Yale University Press, 1953).

- The development of philosophy of language, like the development of philosophy generally in the twentieth century, has taken place at least as much in articles as in books, and the use of anthologies is consequently almost indispensable in the study of it. All the following anthologies contain material useful for the study of philosophy of language in the twentieth century: *Logical Positivism*, edited by A. J. Ayer (Glencoe, IL: Free Press, 1959); *Philosophical Analysis*, edited by Max Black (Ithaca, NY: Cornell University Press, 1950); *Philosophy and Ordinary Language*, edited by C. E. Caton (Urbana: University of Illinois Press, 1963); *Ordinary Language*, edited by V. C. Chappell (Englewood Cliffs, NJ: Prentice-Hall, 1964); *Logic and Language*, edited by A. G. N. Flew (1st series, New York, 1951; 2nd series, New York: Philosophical Library, 1953); *The Structure of Language*, edited by J. Fodor and J. Katz (Englewood Cliffs, NJ: Prentice-Hall, 1964); *Classics in Semantics*, edited by D. E. Hayden and E. P. Alworth (New York: Philosophical Library, 1965); and *Semantics and the Philosophy of Language*, edited by L. Linsky (Urbana: University of Illinois Press, 1952).
- William P. Alston, *Philosophy of Language* (Englewood Cliffs, NJ: Prentice-Hall, 1964), provides a good introduction to the subject as it developed in the first half of the twentieth century. John Passmore, *A Hundred Years of Philosophy* (London: Duckworth, 1957), provides an excellent history of this period and its immediate background, with considerable detail regarding developments in philosophy of language. More specialized and also to be recommended are G. J. Warnock, *English Philosophy since 1900* (New York and

London: Oxford University Press, 1958), and J. O. Urmson, *Philosophical Analysis: Its Development between the Two World Wars* (London: Clarendon Press, 1956).

Norman Kretzmann (1967)

SEMANTICS, HISTORY OF [ADDENDUM]

In the 1960s, the semantics in vogue in linguistics seems to have favored some kind of decompositional approach. Consider kinship terms. Taking *P* to mean “parent of” and *F* to mean *female* you can analyze most kinship terms using first-order predicate logic. So “*x* is *y*’s aunt” would come out as $\exists z \exists w (Pwy \ \& \ Pzw \ \& \ Pzx \ \& \ w \neq x \ \& \ Fx)$. Some linguists, notably George Lakoff (1971) and James McCawley (1972), championed what was called generative semantics, where the idea was that the base level was a semantic level of structures in something such as first-order logic, which could be converted to a surface level. Noam Chomsky’s (1965) level of “deep structure” was thought to lie somewhere between what subsequently became known as the level of “logical form” and the surface level. There were then debates about how autonomous syntax is, and how much of it depends on semantic input. Chomsky himself in *Aspects of the Theory of Syntax* gave an important place to what were called selectional restrictions, one of whose jobs was to rule out sentences such as “Colorless green ideas sleep furiously.”

None of this work however addressed the philosophical question of what semantics really is. For that, the input came from logic. At least since Ludwig Wittgenstein’s *Tractatus Logico-Philosophicus* (1963) and Rudolf Carnap’s *Meaning and Necessity* (1947), the idea had been around that the clue to semantic understanding is in the notion of the truth conditions of a sentence. How might you tell the difference between someone who knows English and someone who does not? You point to a table and utter the sentence: “There is a pen on that table.” First you utter it when the pen is on the table, and then you utter it when the pen has been taken away. You do not need to know English to know the difference between a situation in which there is a pen, and a situation in which there is not, but you do need to know English to know that that difference is correlated with the truth or falsity of a sentence of English. This insight had been at the heart of the languages of logic.

In particular, during the 1960s there emerged the possible worlds semantics for modal logic, whereby an interpretation to a logic provides a set of possible worlds,

and each wff of the formal language has a truth value in each of these worlds. In modal logic the necessity operator written *L* or \Box is so interpreted that $\Box\alpha$ is true in a world *w* iff α is true in every *w*’ that is possible relative to *w*, where relative possibility is specified by a relation of accessibility between worlds. The truth at a world of every complex wff is determined by the semantic evaluation rules associated with each way of getting a more complex wff from its simpler parts—rules such as the one for \Box just mentioned and the rule that $\sim\alpha$ is true in a world iff α is false in that world, and so on. A. N. Prior was at the same time developing interpretations that used moments of time as the semantical indices and interpreted accessibility as the temporal ordering. Such logics were developed for epistemic and deontic operators, though there were those who, mostly under the influence of W. V. Quine (1953), declared that none of this was genuine logic.

But at that time there was still a rift between the logicians, who argued that you could only discuss philosophical issues precisely and profitably in a language that was free from the vagueness and imprecision of natural language, and the ordinary language philosophers who argued that philosophical problems come up in ordinary language and that, as P. F. Strawson had famously claimed, “ordinary language has no exact logic.” The key figure at this point was Richard Montague. During the 1960s Montague began to realize that the languages of intensional logic (logics that involved truth at indices such as worlds, times, and the like) could be used in the semantical study of natural language. Noting that, under Chomsky’s influence, linguists were beginning to realize that the grammatical structures of English sentences could be produced by a set of formal rules, Montague was able to produce fragments of English in which the syntactical rules, such as subject-predicate combination, could be assigned semantic interpretations, which specified how the truth-conditional meaning of a complex structure derived by these syntactical rules could be obtained from the meanings of the simpler parts, from which the complex structure is constructed. Montague’s work (collected in his *Formal Philosophy*) was taken up by Barbara Partee and her students first at UCLA and then at the University of Massachusetts, and has become the dominant tradition in semantics. Montague’s work established a revolution in philosophy as well as linguistics because it became no longer tenable to maintain the distinction between formal logic and natural language.

An alternative tradition, which also developed during the late 1960s and the 1970s, was inspired by Donald

Davidson's *Truth and Meaning* (1967a). Davidson's insight was to apply Alfred Tarski's (1956) work on the semantics of the ordinary predicate calculus to natural language. Tarski had set the goal of semantics as the generation of what came to be called T-schemata. The best known example of a T-schema is "'Snow is white' is true iff snow is white," where the left-hand side says that a certain sentence is true, and the right-hand side states the conditions under which it is true by using the sentence itself. While this has an air of triviality, it is not trivial. The T-schema does not say that "Snow is white" is true iff it is true. It says that it is true iff snow is white, and in a language in which the words are used differently, "Snow is white" would not be true iff snow is white. Suppose that in English *snow* means what *grass* means in English, and vice versa, and that *white* means what *green* means in English. Then the corresponding T-schema in the new language would now be "'Snow is white' is true iff snow is white," but it would now say that "'Snow is white' is true iff grass is green."

Davidson's theory does not make use of worlds or times, and he uses various tricks to get their effect. His theory of indirect discourse (*On Saying That*) treats the *that* in "Galileo said that the earth moves" as being a demonstrative pronoun whose referent is a prior utterance of "The Earth moves," and where the utterer claims that that utterance make him and Galileo samesayers. Another area where the Davidson approach has been applied is that of adverbial modification. Sentential adverbs such as *possibly* or *unfortunately* are the kind that are studied by semantics in terms of worlds, times, and other such indices, but words such as *competently* also need analysis because even if those who drive and those who sing are the same people, those who drive competently need not be the same people as those who sing competently. Davidson's account of adverbial modification (*The Logical Form of Action Sentences*) treats events as individuals, and would analyze, say, "Alice sings competently" as $\exists x(x$ is the singing of a song by Alice and x is competent). Davidson's use of events has been extended by Terry Parsons (1990).

The development of formal semantics raised questions about the connection between the semantical theories provided by logic and the practice of linguistic communication. One way of connecting language with communicative practice is via propositional attitudes, of which the principal ones are knowledge and belief. David Lewis (in *Languages and Language* [1975]) defines a formal model as the correct one for a population if they only produce sentences that are true according to the model

when they have certain beliefs, and trust others to do the same. And Robert Stalnaker (1984) engages with Hartry Field (1978) on the question of whether meaning depends on beliefs, or whether beliefs can only be defined in terms of an internal language.

The connection between meaning and belief forms the focus of one of the most widely discussed issues in the philosophy of language, mainly because of the views of two influential philosophers, Saul Kripke and Hilary Putnam. Kripke (1972) talks about the fact that we can use the word *Aristotle* even though we may know almost nothing about him. Kripke also imagines a person named *Pierre* (A puzzle about belief) who has heard about a beautiful city called Londres, which he believes is pretty. But the part of London that he comes to live in is so dismal that he believes that the city he knows as London is not at all pretty. So, Kripke asks us, does Pierre believe that London is pretty? Putnam (1975) looks at our use of the word *water*. If this word means H₂O, then it would seem that those without a background in chemistry do not know the meaning of what they say.

Recent developments are too many and various to detail adequately here. One, for instance, has involved the claim that semantics should be dynamic. By this, it is meant that the meaning of a sentence should be thought of not so much in terms of its truth conditions as in terms of the potential to change truth conditions. Advocates of dynamic semantics tackle this by thinking of the utterance of a sentence as like a computer program. Instead of a sentence being true or false at an index, think of the first index as being how things are before the sentence is uttered and a second index as being how things are after the sentence has been uttered. One version of this thought appears in *Dynamic Predicate Logic*, found in Jeroen Groenendijk's and Martin Stokhof's 1991 paper. Other dynamic frameworks include those based on Hans Kamp's *Discourse Representation Theory* (or in the more or less equivalent writings of Irene Heim [1983]). A rather different version of a dynamic approach is found in the game-theoretical semantics developed by Jaakko Hintikka (1983).

If the meaning of a sentence is the set of indices at which it is true, we have the consequence that all sentences true at the same set of indices have the same meaning. So for instance, because all mathematical truths are true in all possible worlds, mathematical knowledge would be trivial. However, although the entities used in formal semantics have the job of delivering a set of indices as the final result, any interpreted sentence generates a semantic structure made up from the semantic val-

ues of its simple parts (Lewis 1972, Cresswell 1985). This structure can then provide the input to propositional attitude operators. The kind of indices that have been used in classical truth-conditional semantics are complete in the sense of deciding every sentence—or at least of every sentence that might be said to have a truth value at all. In the 1980s Jon Barwise and John Perry's *Situation Semantics* was based on the view that the entities used in semantics should not be complete. The meaning of a sentence such as "Sebastian laughs" would not be the set of indices at which Sebastian laughs, but would be referred to as a situation, which would be composed of Sebastian, a location, and the relation of laughing that holds between Sebastian and the location at which he laughs.

SEN, AMARTYA K.

(1933–)

Amartya K. Sen, an economist and philosopher, was born in Bengal in 1933. The memory of the Bengal famine of 1943, in which more than 2 million people died, drew him to work on economics and ethics. He studied economics at Presidency College, Calcutta, and Trinity College, Cambridge, where he received a doctorate in economics in 1959. After he taught at the Delhi School of Economics, the London School of Economics, he held the posts of Drummond Professor of Political Economy at Oxford University (also Fellow of All Souls College), and then Lamont University Professor and professor of economics and philosophy at Harvard University. His contributions to economics lie in the areas of social choice theory, theory of choice, development economics, labor economics, cost-benefit analysis, and the measurement of inequality and poverty. In 1998 he was awarded the Nobel Memorial Prize in Economics "for his contributions to welfare economics" and appointed Master of Trinity College, Cambridge.

INFORMATIONAL PARSIMONY OF SOCIAL WELFARE JUDGMENT

The large number of Sen's works in economics and philosophy are marked by tireless criticism of utilitarianism and the utilitarian foundations of welfare economics. According to Sen utilitarianism can be factored into three elements: act consequentialism (the goodness of an act is given by the goodness of its consequent states of affairs), welfarism (the goodness of a state of affairs is given by the goodness of utility information regarding that state), and sum-ranking (the goodness of utility information is given by the sum total of different people's utilities). These elements impose informational constraints on policy judgments and economic evaluation: Act consequentialism does not consider the intrinsic value of an act or the motivation underlying the act; welfarism rules out nonutility information such as violation of rights from influencing the goodness of an act; and sum-ranking excludes

information about the state of people who are worse off. Sen holds that the informational basis for judgments of goodness should include nonutility information and information about the distribution of utility among different people.

Much of his philosophical standpoint originates in the close examination of Kenneth J. Arrow's (1921–) general impossibility theorem: there exists no collective decision-making rule that satisfies some seemingly uncontroversial axioms (unrestricted domain, weak Pareto principle, independence of irrelevant alternatives, and nondictatorship). In *Collective Choice and Social Welfare* (1970a) he scrutinizes the formal and philosophical reach of this theorem and points out the informational parsimony of Arrow's framework. Since Abraham Bergson (1914–2003) and Paul A. Samuelson (1915–) established the "new" welfare economics, individual preference orderings have been assumed to be ordinal and interpersonally incomparable, because there is supposed to be no scientific ground to compare one person's preference satisfaction with another's. Sen shows that if the informational basis is extended to include some kind of interpersonal comparability (e.g., the unit comparability or level comparability), there exist collective decision-making rules, including some egalitarian rules such as *maximin* and its lexicographic extension, *leximin* (as endorsed in John Rawls's difference principle).

INDIVIDUAL FREEDOM AND THE NOTION OF WELL-BEING

In "The Impossibility of a Paretian Liberal" (1970b) he further shows that two conditions in Arrow's theorem (unrestricted domain and weak Pareto principle) are inconsistent with individuals' minimal liberty. Although the weak Pareto principle (if everyone in the society strictly prefers x to y , x is socially preferred to y) is taken to be uncontroversial in economics, it is sufficient to spread the decisiveness of a certain group over all the pair of alternatives, even if the preference over the pair is a purely personal matter that the society should respect. While the same concern led Robert Nozick to his libertarian side-constraint theory, in "Rights and Agency" (1982), Sen adopts a broadly defined consequentialist theory called a goal-right system, according to which individual freedom should be promoted as an end by the society. This moves him to give individual freedom a central role in the evaluation of states of affairs.

In *Commodities and Capabilities* (1985a) he argues against the "opulence" view of well-being (e.g., real income and Rawls's primary goods) and the "utility" view

(e.g., happiness, desire-fulfillment, and the revealed preference theory in welfare economics), and proposes an alternative notion of well-being: the capability to function. He takes human life to consist in a combination of various doings and beings, which he calls functionings (e.g., moving, being well nourished, being in good health, and being socially respected). The capability to function refers to different combinations of functionings, and the capability of a person corresponds to freedom to choose one kind of life among others.

One advantage of this approach is that it takes account of the people's varying capacities to convert primary goods into abilities to pursue their ends. Each person's capability to function is influenced by internal factors such as disability, illness, age, and gender, as well as external factors such as climatic circumstances, educational arrangement, the prevalence of crime and violence, and the resource distribution within the family. What a disabled person can achieve from a larger set of goods may be much less than what an able-bodied person can achieve from a smaller set of goods. The capability approach offers the analytic ground to capture people's diverse needs. This approach changed not only the concept of well-being in ethics but also the paradigm of international development. It became the source of the Human Development Indicators of the United Nations Development Programme.

Through his empirical studies on famines, in *Poverty and Famines: An Essay on Entitlement and Deprivation* (1981), Sen maintains that there has never been a famine in a functioning multiparty democracy: The democratic poor countries such as India, Botswana, or Zimbabwe managed to avert famines despite serious crop failure, whereas the dictatorial countries had major famines. This is because, Sen claims, democracy would spread the penalty of famine to the ruling parties and political leaders, thus providing the political incentives to try to prevent any threatening famine. In subsequent works he champions the notion of human rights for their intrinsic importance, their consequential role in providing the political incentives for economic security, and their constructive role in the genesis of values and priorities.

SENECA, LUCIUS ANNAEUS (4 BCE–65 CE)

A Roman adherent of Stoicism with a particular interest in ethics, Seneca had an extensive career in politics and literature. His *Moral Epistles*, two major treatises, and a series of essays including *On Anger* offer an engaging presentation of philosophical ideas and are an important source for earlier Stoic thought. Also extant are eight plays and a political lampoon.

Seneca was of provincial origin, having been born at Córdoba in southern Spain, but was brought to Rome at an early age. There he received an extensive education in public speaking and literary composition. His knowledge of philosophy came from the lecturers Papirius Fabianus and Sotion (both adherents of Sextian moral philosophy), from the Cynic Demetrius, and from the Stoic Attalus. He won considerable repute as an advocate, but his health was poor and he was in disfavor with the emperors Gaius and Claudius. Exiled by Claudius to Corsica, he was recalled in 49 to become tutor in rhetoric to the boy Nero.

Following Nero's accession he held a position of considerable influence, restraining the young ruler's excesses and composing important speeches for him; as Miriam Griffin has shown, however, his influence on administrative policy was much less than accounts of his career by Tacitus and Dio Cassius would lead one to believe. Late in life he withdrew from politics, transferred his large fortune to the imperial treasury, and devoted himself to philosophical study and writing. His suicide, after being implicated in the Pisonian conspiracy of 65, followed the model of enforced self-execution typical under the Roman emperors.

The major prose works treat a range of topics in ethics, including the theory of value and the human good, character and moral development, moral psychology, self-care and the management of emotion, friendship and political engagement, and practical morality. Occasional forays into logic and metaphysics (primarily in the *Epistles*) and physics (in the *Natural Questions*) are treated as subordinate to ethics. The intention of the mature works to represent the positions of the Stoic founders Zeno of Citium and Chrysippus is not seriously in doubt; there is little to support the claims of an older generation of scholarship for a deliberate program of eclecticism.

While Seneca claims intellectual independence, such claims are themselves in the Stoic spirit of intellectual inquiry. Doctrinal allegiance does not prevent him from studying the writings of Platonists and Epicureans, and he will occasionally endorse a point of doctrine. Epicurus himself he admires for his disciplined personal habits and effective use of various instructional methods. But it would not be accurate to describe him as amalgamating Stoic with Epicurean philosophy, for his criticism of Epicurus's hedonist foundations is as sharp as Cicero's. He is eager to claim common ground among philosophers on such points as do not require him to reverse his Stoic commitments; where definite doctrinal commitments are in evidence, however, his sympathies are decidedly Stoic.

Seneca's major work, the *Moral Epistles to Lucilius* (written between 62 and 65 CE), makes creative use of the epistolary format to present a sustained course of philosophical instruction. Intended for a wide circle of readers rather than for the sole addressee, the collection mingles scenes of daily life with a variety of topics in ethics, psychology, and occasionally metaphysics. The arrangement of ideas is deliberately unsystematic, with some topics treated in cursory fashion and others developed to considerable length. Discussions of particular interest include the non-utilitarian basis of friendship, Platonic ontology, the responsibilities of philosophers to the state, the status of moral rules, and the initial orientation of the human. A more sustained theme is the moral development of the individual as illustrated by that of the author himself and his addressee.

The earlier of Seneca's two full-length treatises, *On Benefits* (written between 56 and 64), is a study of social transactions based on similar works by the Stoics Chrysippus and Hecato. The giving and receiving of various benefactions is analyzed with rigorous attention to the motivation of the giver; there is considerable casuistic elaboration. Very different in character is the *Natural*

Questions (written between 62 and 65), which offers rational explanations for a list of phenomena regularly grouped in antiquity under the heading of meteorology—weather events, comets, earthquakes, and other events whose causes were not directly observable. Like Epicurus, Seneca treats such phenomena as admitting of multiple explanations; this enables him to incorporate a wide range of competing theories into his work. On the whole, however, he maintains the Stoic position on cosmic design, which he sees as having ethical significance: by pondering the regularity of the heavens and the causes of natural events, one can rise above one's ordinary objects of concern and adjust one's thought to the standard of universal reason.

Preeminent among the essays is *On Anger* (complete by 52), in the tradition of Hellenistic anger-management treatises. A careful treatment of the psychology of anger adheres to the Stoic theory of emotions generally: anger is dependent on the rational being's capacity for assent; it is intractable once begun, but can be forestalled by the techniques of cognitive therapy. Among the shorter essays, three are consolatory works of a conventional nature; the remainder treat single topics: the superiority of the virtuous person to suffering (*On Providence*) and to injury and insult (*On Constancy*); the moral end and the supposed hypocrisy of philosophers (*On the Happy Life*); remedies for spiritual malaise (*On Tranquility*); the productive use of time (*On the Brevity of Life*); and the justification for scholarly retreat (*On Leisure*).

The level of doctrinal commitment varies considerably in the shorter essays: Some restrict themselves to a Stoic viewpoint, whereas others, notably *On the Brevity of Life*, are in the spirit of generalized philosophical protreptic. Although the title *Dialogi* is given to the essays in the major manuscript, none is a dialogue in the sense that Plato's works are dialogues. A second speaker is sometimes made to voice an objection, but neither that voice nor the named addressee is developed into a genuine interlocutor. The essay *On Tranquility* does, however, represent its addressee as offering a confessional description of his own moral struggles. This unusual device presages the more extensive experimentation with literary form in the *Moral Epistles*.

The essay *On Clemency* has the greatest political significance of any of Seneca's works. Circulated early in Nero's reign, it celebrates what had become a watchword of the new regime and offers the essentials of a theory of good government based on the character of the ruler. Clemency, or the justifiable mitigation of justifiable penalties, is distinguished both from leniency, which is

unjustifiable mitigation, and pity, which is emotional distress at another's misfortune. Seneca attempts, characteristically, to reform Nero's administration from within, preferring failure to immediate martyrdom; in this, he differs from the hard-line idealism of Thræsea Paetus and other philosophically-minded contemporaries.

Seneca's early rhetorical training manifests itself in his style of writing, which is enhanced with clever turns of phrase, metaphor, and wit. The narrative skills displayed in his eight tragedies and in his political farce, *The Pumpkinification of Claudius*, are put to use in the philosophical prose to give effectiveness to historical anecdotes and, especially in the *Moral Epistles*, to case studies from Seneca's own acquaintance. His interest in combining philosophical with literary achievement is evidenced in his decision to write in Latin rather than Greek, which was the usual language of philosophical discourse among educated Romans of the period. It has been argued by Nussbaum and others that his tragedies are themselves experiments in ethical suasion by literary means; there is some question whether, in that case, the values promoted could remain consistent with Stoic ethics, but certainly it is true that such elements of Stoic cosmology as the cyclical conflagration do appear with some regularity in those works.

SENSA

A distinction is often drawn in philosophy between two types of objects of awareness in perception. First, there are physical objects or substances (such as chairs, books, rocks, and water) and living organisms (animals, plants, and human beings insofar as they are perceptible, that is, their bodies). A common technical term for all these is *material objects*. Second, there are data of immediate awareness, which we shall refer to as "sensa" (singular, sensum), such as color patches or shapes, sounds, smells, and tactile feelings. This distinction is usually fourfold: (a) in status—material objects are external, located in physical space, and "public" (observable by different persons at once), while sensa are private and are usually held to have no external physical existence; (b) in extent—material objects may at one time correspond to several sensa and normally persist throughout the occurrence of many sensa; (c) in directness—the perception of material objects is indirect, that is, it involves inference from or interpretation of sensa that are "given" directly to consciousness; (d) in certainty—one is always certainly aware of sensa but not necessarily so of material objects.

There is no universally accepted term for sensa; *sensations* and *sense data* are commonest but indicate a further subdivision. *Sensation* is customarily used by scientists and psychologists and carries with it the suggestion that sensa are the immediate mental effects of brain activity resulting from the excitation of a sense organ by external stimuli. It and the less specialized term *sense impression* may be used interchangeably for the whole experience of awareness of sound, color, and the like, or for any sensum (such as a sound or a color patch) distinguished within it. The term *sense datum* (plural, *sense data*) apparently originated with G. E. Moore but was introduced in print by Bertrand Russell in 1912. It later became particularly associated with the sense-datum theory of Moore, C. D. Broad, and H. H. Price, while Russell developed different views and came to use other terms.

Sense data are not meant to carry any implications of causal theory, and awareness of them is called sensing (the term *sense datum* is used for the sensum only, not for the whole experience). With the development of the sense-datum theory, controversy arose between those who regarded sense data as objects distinguishable from the act of awareness of them (act/object analysis) and those who denied this and claimed that sensing is really of "sense contents" (adverbial analysis). But the terminology is generally fluid—for instance, some modern neurolo-

gists use the term *sense data* instead of *sensations* in causal contexts. Similar concepts are found in earlier writers, though their language is different. John Locke's "ideas of sense," George Berkeley's "ideas" or "sensible qualities," and David Hume's "impressions" are all forms of *sensa*.

SENSATIONS

It has often been maintained, by philosophers as well as by psychologists, that perceiving consists in the synthesis and interpretation of sensations. But it must be realized that the occurrence of sensations in all perception is only a hypothesis and not an obvious feature of experience. In ordinary language, one may speak of having or feeling sensations of thirst, cold, or pressure and may refer to itches or pains as sensations. But the technical use of the word *sensations* involves a considerable extension of meaning, since one then speaks of visual or auditory sensations (that is, colors or sounds), while such locutions have no place in ordinary speech. We do not have green sensations in our eyes, nor do we normally feel or have sounds in our ears. Admittedly we do have afterimages, spots before the eyes, or ringing in the ears; but these are special cases because, unlike the objects or data of normal perception, the images, spots, or ringing "follows us around" and cannot be avoided by moving the head, closing the eyes, or stopping the ears. Indeed, in normal perception we are conscious not of colored shapes or of sounds as such but of material objects, or at least of ostensible material objects. Admittedly we may sometimes be aware of sounds, smells, tastes, or feelings of pressure, as distinct from objects or object properties, but it is doubtful how far these can be said to be sensations.

Sounds and smells seem public and external: Two or more people may hear the same sound or smell the same smell and agree on its source; sounds travel, and a smell may fill a room. Tastes are a borderline case—private and in the mouth, yet in a sense external to the skin and membranes—while feelings of pressure or warmth are partly sensations proper and partly seem to be awarenesses of heavy or warm objects. However, colors and colored shapes normally seem quite external, public, and at a distance from us.

Sensations in this technical sense (private mental objects of immediate awareness) are thus mainly hypothetical occurrences. Their postulation can be justified only by its success in explaining the facts of perception, and it rests on two grounds. First, there is the causal argument—perception of objects depends on and is conditioned by a chain of causal processes; for example, light waves or sound waves stimulate the appropriate sense

organ, causing impulses to travel along nerves to the brain and activate the appropriate receiving area. Perception cannot, therefore, be direct contact or confrontation with external objects—all immediate awareness must result from the causal process and be an awareness of mental sensations due to brain activity. Since they are thus separated from the external object in time and space, sensations cannot be identified with its properties, though they may resemble them.

Second, there is the psychological argument—many characteristics of perception show that it is not a direct intuitive awareness but involves interpretation of sensations. Thus, error and illusion are really misinterpretations; perception of motion, depth, and distance involves the use of sensory "cues"; and perceptual identification and discrimination are interpretative, not immediate, since they can be improved by learning and experience. (Both these arguments are discussed at greater length under the Perception entry. Here we may simply note some relevant difficulties.)

THE EXTENT OF SENSATIONS. Even if the causal argument forces us to distinguish between external material objects and the immediate objects of awareness caused by brain activity, it does not follow that the latter must be sensations, such as colors or sounds. They may be percepts, that is, mental contents that correspond to whole material objects, though here the psychological argument comes in, suggesting that percepts are the products of interpretation. Supporters of the theory of sensations, no doubt influenced by discoveries concerning the atomic structure of matter, at one time even claimed that the basic sensations are "atomic," that they are sensory point-elements, each corresponding to a different nerve cell—a patch of red color would thus be made up of many sensations of red. This view has now been completely abandoned, largely as the result of the experiments of the Gestalt psychologists, which show that our primary awareness is of organized wholes or figures (*Gestalten* in German), and not of elements into which these wholes might theoretically be analyzed. But even though sensations are not now thought of as minute elements that we synthesize, nonatomic sensations (colored patches of a larger size, or patterns of them, as well as sounds, smells, and so on) may still be regarded as data that we interpret in perception.

AWARENESS AND INTERPRETATION OF SENSATIONS. The awareness of sensations or, for that matter, of percepts must itself be explained; the danger is that it will be construed as analogous to perceiving; for example,

that seeing objects will be explained as seeing sensations caused by them, which is a circular explanation and can thus lead to an infinite regress—seeing sensations must require seeing further sensations, and so on. (Compare the duplication objection to representative realism in the Realism entry). It is therefore necessary to maintain that the awareness of sensations or percepts (“having sensations”) is a special kind of direct awareness different from perceiving, an amendment explicitly adopted by the sense-datum theory.

The problems of the psychological argument are (a) that interpretation of anything would commonly be regarded as presupposing consciousness of what is interpreted, and we are normally conscious neither of having sensations (as opposed to perceiving objects) nor of interpreting them; and (b) that the nature of the interpretation of sensations is controversial—a range of theories is possible because it is not introspectable. The sensationalists (James Mill, J. S. Mill, and others who derived their inspiration from Hume) claimed that perceiving is the association of various sensations. *Association* is a vague term and was explained as the customary linking of ideas or sensations that are similar, contiguous in space and time, and so on. F. H. Bradley and other idealists successfully attacked the sensationalist view as inadequate to explain the facts of perception; instead, they claimed that the interpretation is an inference leading to a judgment, supposing that the possibility of error in perception required this. But this overintellectualized perceiving; inferences and judgments are not the only forms of mental activity liable to error.

ARGUMENTS FOR THE INTRODUCTION OF SENSE DATA

Since the start of the twentieth century, philosophers have made little use of the concept of sensation in their theories but have instead talked of sense data or sense contents. Though the same things—color patches, sounds, smells, and tastes—have been put forward as examples both of sensations and of sense data, the new terminology marks several changes. Recognition of the visual depth or stereoscopic qualities of sense data means that one visual sense datum or color patch is usually held to correspond to the whole of the visible part of an ostensible object (so that one may have striped or variegated sense data). Little detailed attention has been paid to psychological phenomena, except for discussion along traditional lines of error and illusion and their bearing on whether perceiving is a form of judgment. There has also been almost a revulsion from causal arguments, clearly influenced by

their tendency to involve one in the notorious difficulties of representative realism. Instead, a fresh start has been made in the conviction that philosophy has its own distinct contribution to make in the logical and introspective analyses of perception and in the consideration of relevant epistemological issues, that is, of the extent to which perception provides knowledge of external reality. Nevertheless, with some adjustment the new arguments might be supplemented by and in turn supplement the causal and psychological arguments for sensations.

Sense data are defined as whatever is “given” or “directly present” in perceiving; they are the object of *sensing*, of “direct” or “immediate” or “actual” awareness in perception. The claim that this awareness occurs within perceiving is essential to the analysis. To most of its exponents it seems a clear fact of our experience as percipients, one revealed by reflective examination. “Direct” is explained by Price (in *Perception*) as meaning intuitive or “not reached by inference, nor by any other intellectual process.” This formal definition was often supplemented by a kind of ostensive one: Moore, J. R. Smythies, and others gave instructions for looking at an object or scene and picking out the sense datum, such as a colored shape. (Misleadingly, afterimages were sometimes offered as examples of sense data, but their difference from normal perception has already been noted; misleadingly also, some talked of seeing or hearing sense data.)

This definition of sense data naturally raises the question “Why not say that tables, chairs, and other material objects are given or directly seen?” In answering this, these philosophers produce various arguments for distinguishing sense data from material objects.

THE CERTAINTY ARGUMENT. The certainty argument was stressed by Price and by Russell in his search for “hard data,” though it is also found in other sources. Directness or givenness implies certainty—what is given must be limited to what we are absolutely certain of. But in any perceptual situation we cannot be sure that we are aware of any particular material object. For example, an object that seems to be a tomato may in fact be something quite different—a wax imitation, perhaps, or a reflected patch of light, or a hallucination (that is, not be a material object at all). Yet whatever the illusion may be, there can be no doubt, when we seem to see a tomato, that there is given a red, round, bulgy patch of color, a sense datum. Another version of this argument is the method of reduced claims; by confronting him with possible sources of error, you force the person concerned to reduce his

claim from “I see a tomato” to what he actually and directly sees or, rather, senses: “I see a red, round color patch.”

THE PARTITIVE ARGUMENT. When we observe a tomato or a bell, what we “actually see”—the “objective constituent” of the situation, what is given or sensed—is the colored shape that seems to be its front surface. This is a sense datum. We assume that the object has other surfaces and has other characteristics, such as causal properties, three-dimensionality, and persistence in time; and if we loosely say that we see a bell, we imply that we are perceiving an object possessing these properties, although we do not directly see or sense them. This argument, which stresses extent of sense experience rather than certainty, was preferred by Broad and Moore but seems inferior in suggesting that sense data are those parts of an object that we “actually see” on a given occasion—which raises difficulties with respect to illusions.

THE ARGUMENT FROM THE CONTENT OF ILLUSIONS. When a drunkard sees a hallucinatory pink elephant or sees two bottles when only one is present, what is the elephant or second bottle if it is nothing material? The sense-datum theorist answers, “A private object of awareness, a sense datum,” and applies this also to cases of the relativity of perceiving: For example, when a round plate looks elliptical to a person standing at one side, the elliptical appearance cannot be the plate, which is round; it is an elliptical sense datum private to that person. Indeed, it is argued that at all times we are directly aware only of sense data, since there is no qualitative jump between the cases where one cannot be directly aware of an object, and so must be sensing sense data, and the normal cases where we think we are directly aware of an object. This gradation or lack of jump is particularly clear in the case of relativity, as when we gradually move from where the plate looks round to where it looks elliptical, but it also applies to many hallucinations where the illusory *sensa* are integrated with a genuine background. In short, perceiving a material object involves sensing sense data related or “belonging” to it; when the plate looks round to me and elliptical to you, I am sensing a round sense datum belonging to it and you are sensing an elliptical one.

THE FULL SENSE-DATUM THEORY

The fundamental conception of sense data, as directly given elements of experience, spread far beyond epistemology. Both the atomic facts of the logical atomists and the supposedly incorrigible basic or protocol proposi-

tions of the logical positivists had as their prime examples simple statements about sense data (or *sensa* generally), such as “This is red.” But the conception was also developed into a full theory of perception by consideration of the following topics, even though disagreements led to variant accounts.

THE GENERAL NATURE OF SENSE DATA. The arguments for the introduction of sense data, if valid, show that sense data are given and provide examples of them. Further alleged properties emerge from the discussion of illusions and relativity, namely, that sense data (1) are private, each sensed by only one percipient (see argument from the content of illusions); (2) are transitory existents, lasting only while they are sensed, so that they are usually claimed to be events rather than things or properties; (3) are distinct from the percipient and seem to be external (in contrast with sensations); (4) are without causal properties, for sounds (as opposed to sound waves) cannot act on other things, nor can colors or tastes, though the sensing of them may affect a person; (5) cannot be other than they appear to be, or the certainty argument is undermined.

Despite wide agreement on most of these points, a considerable divergence of view arose about (3) and (5). Point (3)—that sense data are distinct from the percipient and seem to be external—involves what came to be called the act-object analysis of sensing. Largely on phenomenological grounds—on how direct experience of color patches, sounds, and such seem to the person concerned—Price and others claim that sense data have distinct existence, that they are objects distinguishable from the act of awareness of them. But some philosophers maintain that the data are only “sense contents” and do not exist apart from the sensing of them any more than does a pain or sensation. This view is formulated in the so-called adverbial analysis of sensing, namely, that “I sense a red color patch” is properly to be regarded as a statement of how I sense or, to put it in a different way, “red color patch” is an internal accusative of the verb *sense*, just as “waltz” is an internal accusative of *dance* in “I danced a waltz.”

There is agreement on point (5)—that sense data cannot appear to be what they are not, for example, sense data cannot appear elliptical when they are round. (Even this is dubious—an apparently pink expanse may, on examination, be found to consist of red dots on a white background.) But some say that sense data can fail to appear as they are (do not reveal their full properties at first sight); thus, one may see that a colored datum is

striped without noting how many or how thick the stripes are. Others deny this, claiming that a closer look results in a fresh sense datum. In fact, the theory cannot deal satisfactorily with the phenomenon of attention. A thing may look quite different on careful examination from the way it looks at a casual glance, and the difference seems to be a matter of how attentively we look, a matter of changes in our mode of observation. In line with this evidence, one should say that sense data may reveal their full properties only on a closer examination, but then one is suggesting that sensing may at times be casual and inattentive and is thus undermining the fundamental claim that sensing is certain and incorrigible.

THE RELATION OF SENSING TO PERCEIVING. The distinction between sensing and perceiving is threefold. First, perceiving is the awareness of some material object; except in certain kinds of illusion this awareness is the result of the object in question (or light or sound from it) acting on the percipient's sense organs. Sensing is the awareness of private sense data that differ from material objects and do not affect the sense organs. Second, sensing is claimed to be direct, immediate, and incorrigible, a form of knowing. Owing to illusions, perceiving cannot be this; it is fallible and indirect. Third, the indirectness of perceiving is said to consist in its being mediated by sensing; perceiving involves sensing, contains sensing within it.

Various views are possible about the nature of this mediation of perceiving by sensing, but they are best expressed as theories of perceptual consciousness. The same kind of consciousness of a tomato, for example, seems present in normal perception, when one sees a tomato as a tomato; in an illusion, when what one sees as a tomato is a piece of wax; and in a hallucination, when no corresponding material thing is there. The kind of consciousness present in these three cases may be called perceptual consciousness and is more conveniently discussed than perceiving, where the implication that there is an object acting on the sense organs complicates the issue.

Some, such as Brand Blanshard (*The Nature of Thought*, London, 1939, Ch. 2), claim that perceptual consciousness consists in sensing a datum and judging or inferring that it belongs to a material object. Price, however, argued that this is too intellectual and does not fit the facts. We unquestioningly accept or take for granted rather than infer or judge, and therefore he defined perceptual consciousness as sensing a sense datum (or data) and taking for granted that it (or they) belong to a mate-

rial object. Others have said that we refer the sense datum to a material object, but *refer* is vague.

Two points of interest arise here. First, philosophers have most often said that we accept or judge that the sense datum belongs to a physical object. This seems obvious only about smells or tastes, and one would on first thought say we assume that the visual sense datum or color patch is the tomato. There is a reluctance on the part of sense-datum theorists to allow this, presumably because they are influenced by the partitive argument or by their knowledge that *ex hypothesi* the sense datum cannot possibly be the physical object. But there seems to be no reason why the ordinary person, whose mental processes are being described, may not mistakenly assume this; one would, for example, say "That patch of white over there on the hill is a sheep" (admittedly, the patch as "public" is hardly a sense datum, but it is the nearest one can get to a sense datum by ordinary examples).

Second, to say that we judge or infer that a sense datum belongs to (or is) a physical object is implausible, for it implies we are conscious of it first as a datum, which is not true to the facts: There is no passage of mind from datum to object, as in inference. Even to say we subconsciously judge or infer is unsatisfactory, for it seems extravagant to suppose that we constantly do subconsciously what we never do consciously. Price attempts to overcome this by maintaining that to take for granted that *A* is or belongs to *B*, one does not need to distinguish them at the time—indeed, the contrary is implied. Sensing thus comes to be regarded as a sort of sensory core within perceptual consciousness, surrounded, as it were, by the further activity of taking for granted. The two states of mind, sensing the red sense datum and consciousness of the tomato, arise together and simultaneously and can be distinguished only by subsequent analysis.

Even this account may be criticized on the grounds that it still does not do justice to the evidence of experience, namely, that perceptual consciousness is one unitary and unanalyzable state of mind, not two. No subsequent analysis of experience reveals sensing as an element within perceptual consciousness. Analysis or reflective examination can result in a "reduced" or critical phenomenological mode of observation in which one distinguishes sounds or colored shapes as such without attributing them to objects, but if this is sensing—and it seems to be the nearest one can get to it—then it is a quite different state of mind from normal perceiving. There is no ground for supposing that this, achievable only by an

effort of analysis, occurs as part of normal unconsidered perception. In general, therefore, the attempt to establish sensing sense data as an omnipresent basic element in perceiving faces the same difficulties that faced the claim that perceiving is the interpretation of sensations.

Another way of seeing the error is to consider the normal usage of “taking for granted.” Price’s analysis is at first sight closest to “*Y* saw the book and took for granted that it belonged to *B*,” but then *Y* is referred to as conscious of the book, while the average percipient is not conscious of sense data as sense data; he is conscious only of the material object. This difficulty can be avoided by the formulation “*X* took for granted that *A* was *B*”; for example, that the piece of wax was a tomato, or that the visitor was the man he was expecting. In each case both *A* and *B* denote the same entity (the wax or the visitor). *A* describes this entity in a way that the speaker knows to be correct; *B* describes it as *X* saw it. Similarly, one might say, “He took for granted that the sense datum (*A*) was a material object (*B*).” But this will not really save the analysis in which the datum and the physical object are alleged to be two quite different entities; to fit the analysis the first phrase (*A*) must also be a description of the alleged object of awareness of *X*, not of the speaker. Price seems to be making the mistake of offering as a description of a percipient’s actual mental content what is in fact a description of the situation that can be made only by someone correcting the percipient’s error.

THE RELATION OF SENSE DATA TO PHYSICAL OBJECTS. One of the vaunted advantages of the sense-datum analysis of perception is its neutrality with respect to the traditional realist theories of knowledge. (Idealism was ruled out by the original claim that sense data are distinct from the sensing of them.) Indeed, sense data were even said to be neutral in that so far as the analysis is concerned, they can be mental or physical or neither. Consequently, it is possible to state the various theories of knowledge in terms of sense data. Naive realism reduces to the view that sense data are parts of the surface of material objects; representative realism would claim that sense data are mental existents caused or generated by cerebral activity ultimately due to material objects and that sense data resemble the properties of these objects. (The second view and, if not too naive, the first also, could admit “wild sense data”—hallucinations that are not part of or caused by physical objects.)

Moore at times toyed with supposing that sense data are parts of the surface of objects (and even seriously discussed whether they might be identical with objects),

though this must have been due to his affection for the partitive argument. The other arguments for sense data and general considerations about illusion do not allow this; for example, a round dish cannot have an elliptical sense datum as part of its surface. Representative realism is a more likely possibility: Neurologists such as Smythies advocate this theory in terms of sense data, and Broad proposed something not unlike it. Most of the philosophers have, however, rejected it in view of its traditional difficulty—if our observation is limited to sense data while material objects are only assumed causes of sense data, then these objects are in fact never observed and therefore may, for all we know, not really exist.

A more common view is that sense data belong to material objects in the special sense that the latter are composed of “families” of sense data. This “family” relationship is not literally one of whole and part, as in naive realism; the material object is supposed to be a complex system or pattern of groups or sequences of sense data. But if a physical object is simply a family of sense data, then when no sense datum occurs—when the object is unobserved—the object must cease to exist. This is felt to be too paradoxical, and two main lines of development within this view have been put forward: (1) phenomenalism, in which the object is regarded as a family of actual and possible sense data—when unobserved, it consists solely of possible sense data; (2) a compromise theory put forward by Price in which the material object, while mainly such a family, contains a physical occupant that persists, even while it is unobserved, as the source of all its causal properties. The notion of a physical occupant has some analogies to Immanuel Kant’s notorious thing-in-itself, and this view has not obtained widespread acceptance.

This divergence of view reflects a central dilemma in the sense-datum theory. If the theory maintains that sense data belong to material objects or that the latter in some way consist of them, then it is difficult to explain (*a*) the persistence of such objects when unobserved; (*b*) the privacy that all versions attribute to sense data—how can a public object be a family of private sense data?; (*c*) the conditioning or even generation of sense data by the sense organs and nervous system, which is required by the physiological facts, by the occurrence of hallucinations or color blindness, and by the effects of attention and learning on perception. (Most sense-datum theorists admit the generation as well as the conditioning.) But if one does not say that sense data belong to or constitute material objects, the distinctness and apparent depth of sense data (at least of visual ones) is difficult to explain;

and, more important, sense data tend to become mental entities like sensations. This, together with the privacy and the generation by the brain, leads one into representative realism.

One attempt to escape this dilemma is to say that sense data are extended and located in their own private “sensible” space along the lines first suggested by Russell in his *Mysticism and Logic* and *Our Knowledge of the External World*. There is one such sensible space, with its own extension and dimensions, for every point in physical space, and the latter in fact becomes the system of points at which sensible space occurs. A physical object is thus, as it were, spread over physical space in a series of “perspectives” or “unperceived aspects,” in the special sense that from different points in physical space, granted that sense organs and brain function properly, sense data may occur in sensible space but also belong to the object as appearances of it and reproduce its characteristics in a way modified both by the viewpoint and by the nature of the sensory apparatus.

This theory is very complex, which means that any summary of it is necessarily garbled. Two of the complexities are that a special interpretation is needed of what we normally call the volume occupied by a physical object and that account must be taken of the different senses, for sight, sound, and touch at least each have their own specific spaces. (Russell later spoke of sensible space as a construct of these spaces, but a construct cannot be the space in which immediately given sense data are located.) A further difficulty is that a given sensible space cannot really be at a point. Not only are the hands, say, at some distance from the eyes, but the brain and the sensory activity associated with perception of an object at one time and place are also really spread over an area. However, the major objection is once again the causation and conditioning of sense data by sense organs and nervous system. How do they influence or produce data in sensible space, or modify the appearance in sensible space of an object in physical space? As soon as one tries to fit in the causal processes, it is difficult to avoid straightforward representative realism, in which all this elaboration becomes unnecessary; perspectives become otiose, except as mere possibilities, or turn into light waves and sound waves. Hence, Russell’s later views gradually approach representative realism (for example, in *Human Knowledge*, 1948).

There does, in fact, seem to be no satisfactory way out of this dilemma for the sense-datum theory. Upholders of it must embrace one horn or the other—they must maintain pure phenomenalism or representative realism. Each has its well-known difficulties, but the second,

though once thought hopeless, is now perhaps more easily made plausible than the first.

DIFFICULTIES CONCERNING SENSE DATA

A number of difficulties have been noted already in the full theory, but others lie even in the arguments for sense data.

THE CERTAINTY ARGUMENT. Various objections may be made to the certainty argument. First, so far as introspective examination is concerned, our awareness is, as we have mentioned, of putative objects, not of color patches—one sees a tomato or something looking like one. Awareness of color patches as such is a different kind of observation from normal perceiving, not a sensory core within it. One may more readily be said to be directly aware of sounds or smells as such; but even then, as we saw concerning sensations, one is aware of them as public and external, not private.

Second, the assumed link between immediacy and certainty is questionable. If immediacy is put forward as an introspective characteristic of the awareness of sense data, nothing follows about its certainty because any awareness we point to as direct may be mistaken. However, if immediacy and certainty are linked conceptually, as the premise of the certainty argument suggests—if they are defined in terms of each other—then it may be that what seems to be immediate, and hence certain, awareness is not immediate. This point may be illustrated in various ways. The certainty argument claims that sensing reveals existents—that when we look at an (apparent) tomato, we cannot doubt that something red and round and bulgy exists. Strictly speaking, however, we are certain only of something red-looking; it may in fact be orange that looks red in this light. Indeed, as J. L. Austin pointed out, even statements about how a thing looks may have to be retracted. Further, the controversy over whether sense data can fail to appear as what they are throws further doubts on the incorrigibility claim, and the alternative adverbial analysis, that sense data are only sense contents, challenges the view that something exists distinct from the percipient’s experience of it.

Third, the certainty argument is too ready to deny that we see physical objects in cases of illusion and distortion and to assume that we are aware of the same kind of existent in both perception and hallucination. Both these assumptions may plausibly be denied. When we look at the putative tomato, even if it is a piece of wax or a reflection of a tomato or an image on a screen, we are

still seeing a material object—wax, or the tomato “in” (via) the mirror, or a screen illuminated in a certain way. There is no need to suppose that we are aware of something else, a sense datum. Contrastingly, the common explanation of hallucinations would be that they are unusually vivid mental images confused with perceptions. Such images, like afterimages, seem to be private, but one should not assume that they are identical with what we are aware of in normal perception. The sense-datum theory can, however, reply that hallucinations are normally quite indistinguishable by the victim from normal perception and may also be integrated with a perceived background—for instance, the apparition may walk across the room and cast shadows—so if the hallucinatory images are private, so must be the data of the background. Although two entities are not necessarily identical because they are generally indistinguishable, identity may be the most plausible explanation of their indistinguishability, and the integration is very difficult to explain except on the sense-datum theory or on some form of representative realism. All the same, the sense-datum theory, if treated as an explanatory hypothesis, has the disadvantage of being very uneconomical in postulating so many distinct entities (the sense data).

THE PARTITIVE ARGUMENT. The partitive argument can be dismissed quite briefly, apart from its other troubles already mentioned. From the fact that we do not actually see the whole of an object at once, it does not follow that we do not then see the object, any more than the fact that we cannot visit all of New York at once means that we cannot visit it at all. Consequently, there is no ground for regarding what we actually see of an object as something different from it (a sense datum) or the actual seeing as some special direct awareness (sensing).

THE ARGUMENT FROM THE CONTENT OF ILLUSIONS. The argument from the content of illusions presents problems similar to those of the certainty argument. The alternative to the sense-datum answer concerning what the drunkard sees in hallucinations is “a mental image,” and in double vision “one bottle looking double.” Neither answer is wholly satisfactory, since the first cannot explain the integration of the image with a real background, and the second has been accused of evading the issue—looking double is not like looking blue or looking elliptical, for it involves an extra apparent object, not a differing quality of the one object.

Ordinary cases of relativity are much more easily dealt with. When one sees a round dish that looks elliptical, one is simply seeing the dish and not some elliptical

existent; the theory oddly assumes that things cannot look other than they are. This assumption is linked with the notion of immediacy: It is gratuitously supposed that in seeing the dish as elliptical, one is immediately aware of an elliptical existent. However, this begs the question by equating immediacy with incorrigibility, so that what looks elliptical is said to be elliptical. Furthermore, there is no cogent ground in experience or in the argument for supposing that nonhallucinatory sense data are private to a person: The elliptical shape of the plate or even the second bottle might also be sensed by others. The privacy is best supported by arguing that sense data are “generated” by brain processes (as in the causal argument for sensations).

OTHER DIFFICULTIES. Various other criticisms of sense data have been put forward, especially by Gilbert Ryle and J. L. Austin. First, sensing is either seeing under another name—in which case there is the reduplication or regress noted concerning sensations—or else it is a myth. The notion of a mistake-proof awareness, Ryle claimed, arises from misunderstanding the character of perception words, which are achievement words or indicate the scoring of an investigational success. One cannot perceive unsuccessfully any more than one can win unsuccessfully, but that is a linguistic or conceptual matter; it does not mean that if one looks or plays, one is bound to see or to win.

Second, the theory, in speaking of sense data as existents, is simply reifying (treating as things) the sounds, smells, or looks of things. Ryle claimed a linguistic origin for this: By wrongly speaking of “seeing looks” or “smelling whiffs,” which are pleonastic usages like “eating nibbles,” the theory tends to treat looks and whiffs as the sort of things we can see or smell—that is, as objects—and fails to see that the point of such words is to show how we are perceiving objects. (He could hardly condemn hearing sounds, even if the other examples are correct.)

Third, Austin attacked the tendency of Moore, A. J. Ayer, and others to distinguish different senses of the word *see*: the normal sense (seeing objects) and the restricted “direct” or “actual” seeing (sensing, which is incorrigible). He claimed that the second sense is a myth: The basic fact is that one may describe the object one sees in various ways, depending on how advertent one is; for example, as a tomato or as a red object. But in these two cases it is the same thing described in different ways, not two different things; nor does it follow that there are two kinds of seeing or two senses of the word *see*.

Austin had other alleged linguistic grounds for the theory's mistakes, such as confusion of illusion with delusion, but it is doubtful whether the several different linguistic origins that he and Ryle claimed for the theory are really genuine and important. The reflective examination of experience seems a more likely origin for the theory, in view of the stress laid on it by the sense-datum philosophers. They have been so struck by the apparent immediacy of perceiving, by its apparently direct confrontation with a "given," that they have readily assumed that it does involve such an immediate awareness or confrontation; and because (on account of illusions) they cannot identify immediate awareness with the perception of a physical object, they have supposed it to be an inner awareness of special data—the sensing of sense data.

FURTHER DEVELOPMENTS

SENSE CONTENTS. As we have seen, the adverbial analysis of sensing claims that *sensa* no more exist as entities distinct from the sensing of them than do itches or pains; consequently, they are often referred to in this analysis as sense contents. Important advocates of this approach have been C. J. Ducasse and Ayer, and under its influence Moore modified and Russell abandoned an earlier faith in an act—object analysis (that sense data are separate entities distinct from the act of sensing). Russell's conversion to the adverbial analysis was brought about by his conclusion that the subject of awareness is a logical fiction; since the act-object analysis presupposes a subject of the act of awareness, it had to be dismissed (*Analysis of Mind*, p. 141). Probably few would follow him on this; it is, at any rate, not clear that the adverbial analysis can dispense with the subject, nor is it clear why one should wish to. Moore's *Refutation of Idealism* relied on the act-object analysis, but he later had doubts about this. He tended to see the problem as whether sense data have any existence when unperceived, or rather, unsensed; that is, whether their *esse* is *percipi* or *sentiri*. He regarded this as an open question, producing various arguments on either side at different times. Actually, the two questions are not quite identical: The adverbial analysis implies that sense data or sense contents cannot exist unsensed, while the act-object analysis is neutral on this.

It seems clear that whether sense data exist unsensed is not a question that can be settled by sensing them. Consequently, some would say it is a purely conceptual matter, one of how sense data are to be defined or how the general theory is to be framed. But factual issues are relevant and present a dilemma similar to the one of the relation of sense data to physical objects. If one accepts

that sense data are generated by the brain, then it seems that they cannot exist unsensed. Even if they are only conditioned by the nervous system, they must appear different from what they really are in the unconditioned, unsensed state, thus undermining the certainty argument. At the same time, to say that a physical object is a family of sense data is scarcely meaningful if sense data do not exist unsensed; therefore, Russell at one period claimed that they do exist unsensed, calling them *sensibilia* in this state. More usually, however, phenomenalism is maintained; sense data do not exist unsensed, but possible ones or possibilities of sensation do.

So far as introspection is concerned, decision between the analyses depends on which sense is considered. Visual sense data, such as color shapes, would seem clearly to be distinct and to require an act-object analysis. (Afterimages are more doubtful, but anyhow are a special case.) Much the same applies to sounds and smells, which are normally experienced as external: By contrast, tactile and other bodily (somatic) sense data, such as pains or feelings of warmth or pressure, and the sensations of movement (kinesthetic data) seem clearly adverbial, as perhaps is taste; but there are marginal cases. Explanation of this variation is difficult for the theory, which would be more plausible if it could give one account of all sense data; it is also difficult to square the distinctness claimed in the act-object analysis with the privacy always claimed. Another possible line, which seems required for dreams and mental images and for hallucinations where no distinct objects are present, would be to say that while sense data seem to the person to be distinct, they are actually contents of adverbial experiences, as are sensations. However, this would undermine the claim of the theory to rely on introspective analysis.

SENSE-DATUM LANGUAGE. One suggestion that has been made is that the sense-datum philosophers have not, as they at first thought, produced a new theory of perception; they have simply introduced a new and more convenient terminology for discussing the facts of ordinary perceiving. This was accepted for a time by those who sought to see all philosophy as dealing with language and by those who, impressed by the difficulties the sense-datum theory encountered, sought to salvage something from the wreck. It is not popular now, for those with a linguistic bias have turned to the examination of ordinary language rather than to the advocacy of new terminologies, while the general decline of support for sense data has proceeded beyond this halfway house. Another reason for supposing that the sense-datum theory was only a terminology was the view that theories must be verifi-

able by observation of predicted consequences, which the sense-datum theory is not, but this seems to confuse a philosophical theory with a scientific theory.

Considered simply as a terminology, the language of sensing and sense data was claimed to have certain advantages; for example, that it is (a) noncommittal—one can describe the contents of one's experience independently of the physical objects they are thought to refer to—and (b) neater than ordinary language, for one can avoid periphrases like “there appears to be a red, bulgy tomato-like object” merely by listing the data sensed. But these are only slight advantages, and it seems that they are far outweighed by the fact that a sense-datum language cannot be truly neutral. It has been so long associated with the sense-datum theory that it must inevitably beg the question by suggesting that the data are private, transitory existents; that one is not “actually seeing” physical objects; or that in describing the scene in terms of visual and tactile data, one has described the experiences of normal perception and not of the different “reduced” phenomenological observation.

SENSATIONS

Readers are advised to consult the historical surveys and then follow up any particular treatment that interests them with the aid of the references given. On the psychological side, see Edwin Garrigues Boring, *Sensation and Perception in the History of Experimental Psychology* (New York: Appleton-Century, 1942) and *A History of Experimental Psychology*, 2nd ed. (New York: Appleton-Century-Crofts, 1950); on the philosophical side, most useful is David Walter Hamlyn, *Sensation and Perception* (New York: Humanities Press, 1961). A stimulating but idiosyncratic discussion is given in Bertrand Russell, *The Analysis of Mind* (London: Allen and Unwin, 1921). Also, many of the books listed below under sense data discuss sensations. Gilbert Ryle's article “Sensations,” in *Contemporary British Philosophy*, edited by Hywel David Lewis, 3rd series (London, 1956), attacks the whole concept; a careful study of a limited field is David Malet Armstrong, *Bodily Sensations* (London: Routledge and Paul, 1962).

SENSE DATA

The following contain statements of the sense-datum theory. Pioneer work is found in George Edward Moore, *Some Main Problems of Philosophy* (introductory lectures of 1910–1911; London: Allen and Unwin, 1953) and his more difficult *Philosophical Studies* (London: Routledge, 1922). He kept returning to the problems of perception, not always consistently; for the advanced student, Alan Richard White, *G. E. Moore* (Oxford: Blackwell, 1958), is a useful guide with a full bibliography. Bertrand Russell was another pioneer in his lucid elementary *Problems of Philosophy* (London:

Williams and Norgate, 1912) and his more significant *Mysticism and Logic* (articles of 1914; London: Allen and Unwin, 1918) and *Our Knowledge of the External World* (London: Allen and Unwin, 1914), but he tended to subordinate the topic of sense data to his special perspective theory. Clear and systematic is Henry Habberley Price, *Perception* (London: Methuen, 1932), which develops a full sense-datum theory. Another well-known account is Charlie Dunbar Broad, *The Mind and Its Place in Nature* (London: Kegan Paul, 1925); earlier and fuller statements of his views, with more attention to causal problems are in his *Scientific Thought* (London: Kegan Paul, 1923) and *Perception, Physics and Reality* (Cambridge, U.K.: Cambridge University Press, 1914). Alfred Jules Ayer gives several clear discussions, mainly from a phenomenalist point of view, in *The Foundations of Empirical Knowledge* (London: Macmillan, 1940), *Philosophical Essays* (London: Macmillan, 1954), and *The Problem of Knowledge* (London: Macmillan, 1956). For a modern version of representative realism stated in terms of sense data, see John Raymond Smythies, *Analysis of Perception* (London: Routledge and Paul, 1956).

There are many criticisms of the sense-datum theory. A general introductory survey, chiefly of Price's version, and extended criticisms are given in Rodney Julian Hirst, *The Problems of Perception* (London: Allen and Unwin, 1959). Gilbert Ryle's criticisms are found in his *The Concept of Mind* (London: Hutchinson, 1949) and *Dilemmas* (Cambridge, U.K.: Cambridge University Press, 1954); John Langshaw Austin's are in his lively defense of a commonsense approach, *Sense and Sensibilia* (London: Oxford University Press, 1962); Roderick M. Chisholm has some succinct criticisms in his more technical *Perceiving: A Philosophical Study* (Ithaca, NY: Cornell University Press, 1957); Harold Arthur Prichard, *Knowledge and Perception*, edited by W. D. Ross (Oxford: Clarendon Press, 1950), attacks Russell and the view that sensing is a form of knowing. Martin Lean, *Sense Perception and Matter* (London: Routledge and Paul, 1953), attacks Broad's version; and valuable is H. H. Price's “The Nature and Status of Sense-Data in Broad's Epistemology,” in *The Philosophy of C. D. Broad*, edited by Paul Arthur Schilpp (New York: Tudor, 1959). On Moore, besides A. R. White's book, senior students should see P. A. Schilpp, ed., *The Philosophy of G. E. Moore* (Evanston, IL: Northwestern University Press, 1942), particularly C. J. Ducasse, “Moore's Refutation of Idealism”; O. K. Bouwsma, “Moore's Theory of Sense-Data”; and Paul Marhenke, “Moore's Analysis of Sense Perception”; and Moore's replies to them.

Among many critical articles, notable are Roderick Firth, “Sense-Data and the Percept Theory,” in *Mind* 58 (232) (1949): 434–465, and 59 (233) (1950): 35–56, attacking the sense-datum analysis of perceptual consciousness; Winston H. F. Barnes, “The Myth of Sense-Data,” in *PAS* 45 (1944–1945); and Anthony M. Quinton, “The Problem of Perception,” in *Mind* 64 (253) (1955): 28–51, criticizing the concept of sense data and the arguments for them; also a more advanced discussion of the earlier versions of the sense-datum theory in the symposia “The Status of Sense-Data,” in *PAS* 14 (1913–1914): 355–406, and “The Nature of Sensible Appearances,” in *PAS*, Supp. 6 (1926): 142–205.

SENSE-DATUM LANGUAGE

The linguistic interpretation of sense data is developed in George A. Paul, "Is There a Problem about Sense-Data?," in *PAS*, Supp. 15 (1936), and A. J. Ayer, "The Terminology of Sense-Data," in *Mind* 54 (216) (1945): 289–312, reprinted in his *Philosophical Essays* (London: Macmillan, 1954); there is a useful discussion of it in the symposium "Seeming," in *PAS*, Supp. 26 (1952): 195–252.

SENSE CONTENTS (ADVERBIAL ANALYSIS)

The most important advocate of this approach is C. J. Ducasse, *Nature, Mind and Death* (La Salle, IL: Open Court, 1951), largely identical with his contribution to *The Philosophy of G. E. Moore*. Brief statements may be found in A. J. Ayer, *Language, Truth and Logic* (London: Gollancz, 1946) and *Philosophical Essays* (London: Macmillan, 1954). A fuller discussion, with emphasis on the differences between the senses, is C. D. Broad, "Berkeley's Argument about Material Substances," in *Proceedings of the British Academy* 28 (1942): 127ff., and his *Scientific Thought* (London: Kegan Paul, 1923).

SENSATIONALISM

"Sensationalism," the doctrine that all knowledge is derived from sensations, takes several closely related forms. As a psychological theory it stresses the origins of knowledge and the processes by which it is acquired; it seeks to reduce all mental contents to unitary sensations and has close connections with associationism. It is sometimes, as by its acute but sympathetic critic James Ward, called presentationism. As an epistemological theory it tends toward the view that statements purporting to describe the world are analyzable into statements concerning the relations between sensations and that this analysis elucidates the meanings of the original statements. It is sometimes regarded as a form of empiricism and adopted with antimetaphysical intentions.

Sensations are usually regarded as occurrences in us, either caused by external objects (Epicurus and John Locke) or not meaningfully attributable to external causes (James Mill and Étienne Bonnot de Condillac). By some they are explicitly likened to feelings or emotions (Anaxagoras and David Hartley), and by others to images (Ernst Mach); the more modern forms, however, probably depend, even if not explicitly, on taking them all as analogous to feelings.

There is a tendency to associate sensationalism with the nineteenth and twentieth centuries, as a development of the work of the empiricists of the seventeenth and eighteenth centuries, but it actually has a long history. A study of its development takes us back to the pre-Socratics, and although in its modern forms it usually leans heavily on the distinction between sensation and perception, there were views that can be called sensationist long before the distinction was made (for example, Protagoras held them). The distinction between sensation and perception is used because it is believed that although perception involves interpretation and, thus, the possibility of error, sensation does not. Sensationalism is therefore sometimes looked upon as the end point of the empiricists' quest for certainty and a sure foundation for knowledge.

THE GREEKS

The Greeks had no linguistic means of distinguishing between sensation and perception, but they do not appear to have considered this a serious lack. The pre-Socratics were apparently interested in perception mainly from the physiological and physical point of view; they wanted to describe processes, which they tended to see as purely mechanical (this is especially true of Empedocles

and the atomists), involving the meeting of effluences from the sense organ and the external object. But Anaxagoras introduced a feature that has some significance for an understanding of sensationalism—namely, the idea that perception involves pain. This facilitates the assimilation of all sensations to feelings referred to below.

PROTAGORAS. Protagoras, accepting the Heraclitean view that all is change or becoming and having concluded that “man is the measure of all things,” found it easy to regard our constantly changing sense experiences as the objects of knowledge and to hold that all the so-called qualities of things, not merely the secondary qualities as the atomists believed, were relative to the perceiver. This turned attention to epistemological questions connected with the nature of perception.

PLATO. Perhaps Plato and Aristotle were primarily reacting against this view of Protagoras in their discussions of perception. Plato’s argument in the *Republic* is that sense experience does not give knowledge but only opinion, since knowledge must be certain and cannot be of what is constantly changing—that is, sensations or the sensible world. According to some scholars—D. W. Hamlyn, for example—another view can be extracted from the later dialogue the *Theaetetus*, but this is highly controversial. Protagoras was referring to knowledge of a familiar, everyday sort. The view allegedly to be found in the *Theaetetus* is that the senses can give us this rudimentary empirical knowledge; they give us direct acquaintance with the outside world and even without interpretation can therefore give us knowledge. There is no distinction to be made, as far as the sensible world itself is concerned, between what is and what appears. Because sense experience is caused by the external world, it can be regarded as infallible. But this step is suspect both on general grounds and in relation to Plato’s own insistence that the categories of right and wrong are contributed by the mind. His thought seems to be that if judgment is made by the mind and if saying that something is wrong is making a judgment, then bare sense experience, being prior to judgments of it, cannot ever be said to be wrong. It should, of course, be added that it cannot be said to be right either.

ARISTOTLE. Aristotle, in attempting to refute the sensationalism of Protagoras, stressed the element of judgment in perception and almost arrived at the distinction between sensation and perception. At the same time he appears to admit an important feature of sensationalism. Each sense has its proper object or special sensible; the

proper object of hearing is sound and that of sight is color. But there are also common sensibles, qualities of objects that are not specially related to any one of the five senses but that are related to the common nature of them all, which he referred to as the common sense. These qualities are, roughly, the primary qualities motion, rest, shape, size, and number. Because there is a necessary connection between each sense and its special sensible, it is impossible for the senses to make mistakes about them; for example, hearing cannot err about the fact that it is concerned with sound and not color. This, however, does not entail any incorrigibility in the deliverances of the senses as is required by sensationalism. It simply means that each sense is necessarily concerned with its special sensible. Aristotle’s claims about incorrigibility probably arise, as Hamlyn says, from an unresolved conflict between his view of the senses as both active and passive. (The senses can make mistakes only if they are active and make judgments; as mere passive receptors, they cannot. If we fail to distinguish in this way, we may think of the senses as judging infallibly.) In *De Memoria et Reminiscencia* Aristotle outlined some principles of association that look forward to later accounts.

EPICURUS. Epicurus, who believed that sense perception is the source of all knowledge, held a causal theory of perception. He did not distinguish between sensation and perception and regarded what were later called sensations as incorrigible because caused. He was an atomist and attempted a mechanical account of perception. The Stoics opposed this account and again stressed the importance of at least rudimentary judgment in perception. Their conception of *phantasiae* roughly corresponds to the conception of sensations as images; they held that these were not necessarily veridical although some of them were intuitively certain.

THE SCHOLASTICS

Problems of perception were not central in medieval philosophy except as they bore on the relation between empirical and other varieties of knowledge.

AUGUSTINE. Augustine is important on the subject of perception perhaps only because he saw that it is not meaningful to talk of sensations as either true or false; these terms can be applied only to judgments. He simply assumed that sense impressions correspond to the external world but regarded the knowledge thus obtained as of the lowest kind.

THOMAS AQUINAS. Thomas Aquinas followed Aristotle in his views on perception to the extent of holding that it involves the reception of a sensible form without matter, but this produces a change in the soul, not merely, as for Aristotle, in the sense organ. Sensory images (*phantasmata*) are received passively, but they are images of external objects. They have the peculiarity that we are not aware of them. The mind abstracts universal qualities from these and uses them in making judgments. The senses and the intellect are closely connected: *Nihil est in intellectu quod non prius in sensu* (Nothing is in the intellect that was not first in the senses). Because our perceptions involve judgments, they may or may not be veridical, but the *phantasmata* are not appropriately called either. This, with the fact that the *phantasmata* are images of something, prevented Thomas from being a sensationalist, but he was very close to being one in spirit and utterance.

OCKHAM. Although William of Ockham differed from Thomas in many ways, he also distinguished a sensible and an intellectual element in cognition. Those cognitions that involve only immediate experiences are said to be perfect. Error arises in judgment, but when we are directly apprehending something, we are not in error.

THE SEVENTEENTH AND EIGHTEENTH CENTURIES

Sensationalism proper can perhaps be regarded as the product of a steady development of empiricist ideas from the seventeenth century to the nineteenth. Thomas Hobbes is sometimes credited with its inception, but his sensationalism is rudimentary. He did have some conception of the association of ideas and, of course, contributed to the foundations of empiricism.

Largely because of the climate of scientific opinion, involving as it did a growing belief in the importance of observation and experiment, the philosophers of the seventeenth century were much concerned with problems of perception. They were especially interested in the elimination of errors arising from sense experience and in the attempt to make our knowledge of the natural world as reliable as possible. The rationalists attempted to show that knowledge could be based on indubitable truths of reason, independent of sense experience. The empiricists sought a hard core of indubitable truths involved in sense experience upon which all knowledge could be based.

GALILEO. Galileo Galilei distinguished between primary and secondary qualities and thought that secondary qual-

ities existed only as sensations in us. They are, however, caused by primary qualities in objects, especially by shape and motion.

HOBBS. Under the influence of Galileo, René Descartes, Marin Mersenne, and Pierre Gassendi, Hobbes developed the philosophy of motion into what must be the most thoroughgoing materialism there has ever been. For him all our inquiries must start from sense experience, but there are certain principles—for instance, that motion cannot be understood to have any other cause besides motion—which we know independently of sense experience and upon which other knowledge depends. Nothing exists but matter in motion, so sensations are material changes in us that somehow mediate between motions in the external world and the minute motions of our bodily parts. Hobbes assumed the existence of external motions causing our sensations; knowledge of these “objects” can come only through sensations. This does not entail the empiricist view that all knowledge is reducible to knowledge of sensations; Hobbes was in general a rationalist, for he held that certain truths of reason are essential even for that knowledge of the natural world which depends upon sensation.

LOCKE. Locke’s work marks the beginning of the growth of sensationalism proper, although he was not himself a sensationalist just because he did not develop his particular form of empiricism consistently. His “ideas of sensation” are close to what were later called simply sensations, but his representative theory of perception and his assertion of the existence of substance entail that in spite of explicit claims he relied on knowledge which did not come entirely through sensation.

BERKELEY. George Berkeley attempted to remove this inconsistency in his attack on material substance and representative perception. Whether we view his reliance on God as the unempirical importing of a concept merely for the purpose of filling an embarrassing gap—that is, to allow us to hold that objects continue to exist when no human being is perceiving them—or as the attempt to delineate a concept that is logically necessitated by our experience, Berkeley’s account of ideas brings us very near sensationalism. There is no talk of external objects that are composed of any material different in kind from what we directly know—that is, ideas. Later sensationalism can be regarded as comparable to Berkeley’s system without God, with all its problems as well as its advantages.

HUME. David Hume continued this development, in one direction by rejecting mental substance, which was retained by Berkeley, as well as material substance. The world for us, as far as we can justifiably say in philosophical contexts, consists of impressions and ideas, and knowledge is of relations between these. Hume was not, however, as great a skeptic as is often alleged. We have, naturally, certain beliefs—for example, in the external world and in causal efficacy—which cannot be rationally supported. When philosophy fails to provide this rational support, so much the worse for philosophy. If Hume had not been affected by the common view that knowledge implies certainty, he would no doubt have admitted these “natural” beliefs as knowledge and thus have been farther from sensationalism in his official theory than he actually was.

Sensationalism in its fullest sense is best seen in the works of Hume’s lesser-known contemporaries Hartley and Condillac. Hartley’s work was later developed by James Mill, and its most thoroughgoing exponent in the nineteenth century was perhaps Mach.

HARTLEY. Hartley was a medical man; his interests were largely physiological, and his work stimulated the development of a school of psychology. His basic concepts were sensations and the association of ideas, for which he admitted a debt to Locke and Isaac Newton. All mental occurrences originate in sensations caused by vibrations of minute particles of the brain set off by external stimulation. Simple ideas are “copies” of sensations—that is, physiologically they are tiny vibrations corresponding in character to the original vibrations and left behind by sensations when the stimulus is withdrawn. Complex ideas are built up from these by association according to certain discoverable principles. The vibrations occur in a subtle elastic fluid in the medullary substance of the nerves and brain. This mechanical account is reminiscent of Hobbes’s view and admittedly owes a debt to Newton’s mechanistic philosophy. The conception of the association of ideas springs from Locke, and the consequent contention that ideas are copies of sensations echoes Hume’s account of impressions and ideas. Hartley’s theory leads to the conclusion that we are aware only of occurrences within ourselves but that these depend for their character on the external world. There is a twofold correspondence, between ideas and sensations and between sensations and stimuli.

JAMES MILL. James Mill accepted Hartley’s basic conceptions and developed the psychological side of the theory. Hartley had expressed in terms of vibrations two princi-

pal determinants of the strength of association—the vividness of the sensations and the frequency of their conjoint occurrence. Mill discussed these principles in some detail, without Hartley’s preoccupation with vibrations, contrasting his principles of association with Hume’s and using some rather unsatisfactory arguments for preferring his own. In place of Hume’s contiguity in time and place, causation, and resemblance, Mill put synchronous order and successive order, which include causation as a special case, and vividness and frequency, which include resemblance as a special case. He went further than Hartley in considering the relation of sensations to the external world; external objects for him are “clusters of sensations.” Most of our beliefs about them depend on sight and sensations of color, with which we associate the other properties we attribute to them.

CONDILLAC. While Hartley was writing in England, Condillac was developing similar ideas in France. He was a disciple of Locke, and his first book was largely an exposition of Locke’s philosophy. In his *Traité des sensations*, he developed his own psychological theory, largely in opposition to the various current conceptions of innate ideas. He set out to show that all knowledge is “transformed sensation” and does not depend upon anything else, even, as Locke would have had it, reflection. He examined the nature and power of each of the senses by imagining a statue that has all the human faculties but has never had a sense impression. He then allowed its senses to be activated, one by one and in various combinations, and asserted that the results showed how all knowledge can gradually be constructed. He concluded that people consist of their experiences and that what they perceive is their own mental occurrences. Unlike Hartley, he did not try to give a mechanical account of these occurrences, being more concerned with psychology than physiology, and he admitted the reality of the soul. He had a considerable influence on the beginnings of British psychological thought through James Mill and J. S. Mill, Alexander Bain, and Herbert Spencer.

MACH AND TWENTIETH-CENTURY EMPIRICISM

Whereas Hartley, Condillac, and the Mills were interested in sensations mainly in relation to psychology, ethics and politics, Mach’s interest sprang from an attempt to provide an analysis of the methods of the physical sciences. His sensationalism was associated with a search for a solid foundation for scientific statements and with a desire to free science of all metaphysics. He held that only state-

ments which are directly verifiable in sense experience can finally be accepted as conclusions in the sciences. He concluded that all scientific statements are analyzable into statements about the relations between our sensations and that nothing can be said, scientifically, about anything beyond this. In a sentence reminiscent of James Mill he said, "The world is my sensation." It follows, also, that the various branches of science do not differ in subject matter but only in their approach to the subject matter, which is—alike for all—sensations; this was the basis of the "unity of science" movement and the logical positivism of the Vienna circle.

Mach's work was very much in harmony with the spirit of his time, especially in relation to the physical sciences, and has had an important influence on later philosophical thought. He admitted a debt to Berkeley and Hume and a number of his philosophically minded scientific contemporaries. His idea that the world is composed of "elements" which can be regarded either as sensations or the constituents of physical objects has close connections with Bertrand Russell's neutral monism and logical atomism, and his description of the aims of science is similar to that of pragmatism and operationism. In one way or another, most empiricist thought about science during the twentieth century has been influenced by his work. Recent philosophical theories of perception involving sense data or *sensa* are in the direct line of descent insofar as they stress the mind dependence of sense data, our direct awareness of or acquaintance with them, and the alleged incorrigibility of certain sorts of statements about them. Such theories can be regarded as attempts to refashion Mach's form of sensationalism in order to avoid some of the obvious objections to it.

Sensationalism and related theories all suffer from one defect, which renders the whole approach suspect; under the heading "sensations" they class together things that it is important to distinguish—for example, such sensible qualities as colors and sounds; bodily aches and pains; desires and emotions; and such feelings as dizziness, anger, and jealousy. We would not normally be prepared to class all these as experiences, but certain empiricist contentions—for example, that we know colors only through their effects on us—can make it seem superficially plausible to call them all sensations. Just because this blurs the distinctions between various things included under the heading, sensationalism as a general theory gains plausibility. Toothaches and certain feelings have an air of immediacy and unmistakability that may lead us to suppose that color sensations, since they, too, are sensations, are ultimate and incorrigible data for the

construction of a world picture. I can be certain that I have a toothache, and no one can be better justified than I in asserting or denying this. If color sensations can be assimilated to toothaches, there might seem to be some hope of arriving at incorrigible statements about the external world. Hence, the importance of the clue afforded by Anaxagoras's view that perception involves pain. A close examination of experiences of color and other sorts of experience reveals that the necessary assimilation is seriously misleading; moreover, it brings in its train enormous difficulties for an account of science. On one hand, incorrigibility can be achieved, if at all, only with the loss of the publicity of the statements concerned; on the other hand, it is difficult or impossible to show how scientific problems could ever arise if sensationalism were correct, since there is no reason that any particular combination of sensations should or should not follow any other.

In fact, the word *sensation* suffers from ambiguities similar to those involved in the word "idea" as used by Locke and Berkeley; as *sensation* must do even more work than *idea*, the ambiguities are correspondingly more serious. The view of science that springs from sensationalism, according to which science describes but does not explain, suffers further from insufficient consideration of the nature of description and its relation to explanation and from a failure to appreciate the difficulties involved in the idea of describing sensations.

SENSATIONS

See *Sensa*

SENSE

"Sense" is the distinctive central notion in theories of thought and language inspired by the later work of Gottlob Frege ("sense" translates Frege's *Sinn*). For Frege what we think (not the act of thinking it) is a thought, an abstract object. Thoughts have quasi-syntactic structure. Any simple or complex constituent of a thought, even the thought itself, is a sense; thus, senses are abstract. Frege assumes that it is irrational to assent to a thought and

simultaneously dissent from it. Since someone misled about astronomy may rationally combine assent to the thought that Hesperus is Hesperus with dissent from the thought that Hesperus is Phosphorus, the thoughts are distinct. Although the names "Hesperus" and "Phosphorus" have the same reference, they express different sense, two modes of presentation of one planet. The role of a sense is to present the thinker with a reference—that is, something on which the truth-value (truth or falsity) of the thought depends; if the sense fails to present a reference, the thought lacks a truth-value. For Frege the truth-value of a thought is independent of where, when, and by whom it is thought. Thus, what reference a constituent sense presents is independent of when, where, and by whom it is thought. Sense determines reference, not vice versa.

Frege used his notion of sense to analyze the semantics of thought attributions in natural language, as in the sentence "Someone doubts that Hesperus is Phosphorus." On Frege's account expression within such "that" clauses refer to their customary senses. This explains the presumed failure of the inference from that sentence and "Hesperus is Phosphorus" to "Someone doubts that Hesperus is Hesperus": The two names have different references within "that" clauses, for their customary senses are different. If sense determines reference, then the sense of "Hesperus" in "Someone doubts that Hesperus is Phosphorus" defers from its sense in "Hesperus is Phosphorus," since the reference differs. By appeal to iterated attributions such as "He doubts that she doubts that Hesperus is Phosphorus," it can be argued that Frege is committed to an infinite hierarchy of senses. His account involves the assignment of senses to natural-language expressions. However, in order to understand many words (e.g., proper names and natural-kind terms), there is arguably no particular way in which one must think of their reference; they do not express senses common to all competent speakers. Fregeans therefore distinguish sense from linguistic meaning but in doing so sacrifice Frege's original account of thought attributions.

Sense must also be distinguished from linguistic meaning for context-dependent expressions such as "I." Two people may think "I am falling" and each refer to themselves, not the other. Since the references are distinct and sense determines reference, the senses are distinct, even though the mode of presentation is the same. Others cannot think the sense that one expresses with "I"; they can only think about it. Communication here does not amount to the sharing of thoughts, and "You think that I am falling" does not attribute to the hearer the

thought that the speaker expresses with “I am falling.” In contrast, the linguistic meaning of “I” is the same for everyone; it consists in the rule that each token of “I” refers to its producer. Unlike a sense, the rule determines reference only relative to context. Such cases reveal tensions within Frege’s conception of sense. Sense cannot be both what determines reference and how it is determined. Since senses can be qualitatively identical but numerically distinct, they are not purely abstract objects, if qualitatively identical purely abstract objects must be numerically identical.

Although Fregeans distinguish sense from linguistic meaning, they still treat a given speaker on a given occasion as expressing senses in words. Frege gave the impression that the sense expressed by a word was a bundle of descriptions that the speaker associated with it: the word refers to whatever best fits the descriptions. However, this descriptive model of reference has fared badly for proper names and natural-kind terms. Nondescriptive models may also allow different routes to the same reference, but that is a difference in sense only if it is a difference in presentation to the thinker.

In spite of these problems a role for something like sense remains. An account is needed of the deductions that thinkers are in a position to make. When, for example, is one in a position to deduce “Something is black and noisy” from “That is black” and “That is noisy”? It is necessary but not sufficient that the two tokens of “that” refer to the same thing, for, even if they do, the thinker may lack evidence to that effect: Perhaps one refers through sight, the other through hearing. What is needed is more like identity of sense than identity of reference. Thus, the theory of rational inference may still require a notion of sense. It does not follow that thinkers are always in a position to know whether given senses are identical, for it is not obvious that they are always in a position to know what deductions they are in a position to make.

SERVETUS, MICHAEL

(1511–1553)

Michael Servetus, the Spanish theologian and physician, was born in Spanish Navarre and was burned at the stake in Geneva. In the history of medicine he is remembered for having been the first to publish a description of the pulmonary circulation of the blood, and in the history of theology, he is noted for his systematic refutation of the Nicene doctrine of the Trinity. In philosophy, he developed a Christocentric pantheism that included elements from the Neoplatonic, Franciscan, and kabbalistic traditions. It should be pointed out, however, that he believed that natural philosophy should be grounded in empirical investigation.

After studying the three biblical languages as well as mathematics, philosophy, theology, and law at the universities of Zaragoza and Toulouse, Servetus, in the capacity of secretary, accompanied Juan de Quintana, the Franciscan confessor of Emperor Charles V, to the latter’s coronation in Bologna. Breaking with the imperial court, he went on his own to Basel, where he sought out John Oecolampadius, and then went on to Strasbourg, where he had some contact with Martin Bucer and, in particular, Wolfgang Capito. In nearby Hagenau he had printed his *De Trinitatis Erroribus* (1531) and, in response to Bucer’s critique, the more moderate and more Christologically oriented *De Trinitate* (1532). In Strasbourg Servetus met Kaspar Schwenkfeld, from whom he may

have taken over a heretical idea about the celestial flesh of Christ. In Strasbourg he may also have come in contact with the Anabaptists, whose views on baptism he was later to espouse. By way of Basel, where he tried to get Desiderius Erasmus's approval of his *De Trinitate*, he went to Lyons, where he worked as a proofreader and began his study of medicine under the Neoplatonizing Symphorien Champier. Next he went to Paris, where by chance he met John Calvin and got into trouble with the medical faculty over his views on astral influences. His *Apologetica Disceptatio pro Astrologia* (1538) marks an important turning point in Servetus's evaluation of the place of Greek philosophy. Whereas before he had regarded the influence of philosophy on theology as corrupting, he was now prepared to speak of "*divinus Plato*," on whose authority he defended astrology. After establishing himself in Vienne as physician to the archbishop, he engaged in correspondence with Calvin and composed the recently discovered and identified *Declaratio Jesu Christi Filii Dei* (c. 1540). Out of this grew his more massive *Restitutio Christianismi* (1553). Through the machinations of Calvin himself, Servetus was apprehended and tried for heresy, first in Catholic Lyons and then, after his escape, in Calvinist Geneva, where, after refusing to recant, he was burned at the stake.

Servetus's view of nature, history, and salvation was centered on the figure of Jesus Christ, whom he considered to be in a quite physical sense the Son of God. Servetus declined, however, to call the earthly Son eternal and declined to call either the Word or the Spirit *personae*; rather, he called them, neutrally, *res*—that is, in a modalist sense, the faces, forms, images, or manifestations of God. He mistakenly regarded the traditional *hypostasis* (*persona*) and *substantia* as equivalent, and hence, to avoid what he considered an unbiblical tritheism, he called the Father or Jehovah alone God. Before the Incarnation the Word was Elohim, or Uncreated Light. Indeed, this Light, or alternatively Christ (as distinguished from the earthly Son, Jesus), was also "the eternal sea (*pelagus*) of ideas." The Spirit has always been a Power of God, working outwardly in the world as his breath (*flatus*) and inwardly as the agitation, or motion, of the human spirit at regeneration.

The way in which the Uncreated Light became the Second Adam in Mary was for Servetus paradigmatic of the process by which creative Light was ever penetrating matter to form minerals, plants, animals, and all created things. For Servetus "even the treasures of natural science are hidden in Christ." Connected with his speculation on Light was Servetus's concept of the Shadow, according to

which he was able to regard all of the Old Testament and all religion outside the Bible as a shadowing forth of the Son that was to be born of Mary. He cherished the old Law as a pregnant woman bearing the embryonic Christ until the fullness of time.

Servetus rejected post-Constantinian (post-Nicene) Catholicism because of its alleged tritheism and its use of political force in the realm of conscience. He also opposed the Reformation churches because of their use of force, their denial of free will in accepting redemptive grace, and their neglect of sanctification, which he understood as communicated in an almost physical sense through the believers' baptism at the age of thirty (in imitation of Jesus). Nevertheless, in common with the Spiritual Libertines and some Anabaptists, Servetus held to the provisional death of every soul with the body pending the general resurrection. Under the influence of Joachimite speculation, he believed that the true church would be restored in the year 1560.

SET THEORY

Set theory is a mathematical theory of collections, "sets," and collecting, as governed by axioms. Part of its larger significance is that mathematics can be reduced to set

theory, with sets doing the work of mathematical objects and their collections and set-theoretic axioms providing the basis for mathematical proofs. With this reduction in play, modern set theory has become an autonomous and sophisticated research field of mathematics, enormously successful at the continuing development of its historical heritage as well as at analyzing strong propositions and gauging their consistency strength.

Set theory arose in mathematics in the late nineteenth century as a theory of infinite collections and soon became intertwined with the development of analytic philosophy and mathematical logic. The subject was then developed as the logical distinction was being clarified between “falling under a concept,” to be transmuted in set theory to “ $x \in y$,” x is a member of y , and subordination or inclusion, to be transmuted in set theory to “ $x \subseteq y$,” x is a subset of y . That set theory is both a field of mathematics and serves as a foundation for mathematics emerged early in this development.

In what follows, set theory is presented as both a historical as well as an epistemological phenomenon, driven forward by mathematical problems, arguments, and procedures. The first part describes the groundbreaking work of Georg Cantor on infinite sets analyzed in terms of power, transfinite numbers, and well-orderings. The next two parts describe the subsequent transmutation of the notion of set through axiomatization, a process to be associated largely with Ernst Zermelo. Next will come a description of the work of Kurt Gödel on the constructible sets, work that made first-order logic central to set theory, followed by a description of the work of Paul Cohen on forcing, a method that transformed set theory into a modern, sophisticated field of mathematics. The last section describes the modern investigation of relative consistency in terms of forcing, large cardinals, and inner models.

POWER, NUMBER, AND WELL-ORDERING

Set theory was born on that day in December 1873 when Cantor established that *the continuum is not countable*. The concepts here are fundamental: Taking infinite collections as unitary totalities, a set is *countable* if it is in one-to-one correspondence with the set of natural numbers $\{0, 1, 2, \dots\}$, and the *continuum* is the linear continuum regarded extensionally as a collection of points corresponding to the real numbers. In a 1878 publication Cantor investigated ways of defining one-to-one correspondences between sets. For sets of real numbers and the like, he stipulated that two sets have the same *power* if

there is a one-to-one correspondence between them and that a set x has a *higher* power than a set y if y has the same power as a subset of x yet x and y do not have the same power. He managed to show that the continuum, the plane, and generally n -dimensional Euclidean space all have the same power, but at this point in mathematics there were still only the two infinite powers as set out by his 1873 proof. Cantor at the end of his 1878 publication conjectured:

Every infinite set of real numbers either is countable or has the power of the continuum.

This was the *Continuum Hypothesis* (CH) in its nascent context. The *Continuum Problem* would be to resolve this hypothesis, and viewed as a primordial problem it would stimulate Cantor both to approach the real numbers in an increasingly arithmetical fashion and to grapple with fundamental questions of set existence.

In his magisterial *Grundlagen* of 1883, Cantor developed the *transfinite numbers* and the key concept of *well-ordering*. Investing the “symbols of infinity” of his early trigonometric series investigations with a new autonomy, Cantor conceived of the transfinite numbers as being generated by the operations of taking successors and of taking limits of increasing sequences. Extending beyond the finite $0, 1, 2, \dots$, the progression of transfinite numbers could be depicted, in his later notation, in terms of natural extensions of arithmetical operations:

$$0, 1, 2, \dots, \omega, \omega + 1, \omega + 2, \dots, \omega + \omega (= \omega \cdot 2), \dots, \omega \cdot 3, \dots \\ \omega \cdot \omega (= \omega^2), \dots, \omega^3, \dots, \omega^\omega, \dots$$

Definition. A binary relation $<$ is a *linear ordering* of a set a if it is transitive, that is, $x < y$ and $y < z$ implies $x < z$, and trichotomous, that is, for $x, y \in a$, exactly one of $x < y$, $x = y$, or $y < x$ holds.

A relation $<$ is a *well-ordering* of a set a if it is a linear ordering of the set such that every non-empty subset has a $<$ -least element.

Well-orderings convey the sense of sequential counting, and the transfinite numbers serve as standards for gauging well-orderings. As Cantor pointed out, every linear ordering of a finite set is already a well-ordering and all such orderings are isomorphic, so that the general sense is only brought out by infinite sets. For these there could be non-isomorphic well-orderings. For example the set of natural numbers $\{0, 1, 2, \dots\}$, that is, the predecessors of ω , can be put into one-to-one correspondence with the predecessors of $\omega + \omega$ by sequentially counting the evens before the odds. In fact all the infinite transfinite numbers in the above display are countable. Cantor

called the set of natural numbers the first number class (I) and the set of numbers whose predecessors are in one-to-one correspondence with (I) the second number class (II). Cantor conceived of (II) as bounded above according to a limitation principle and showed that (II) itself is not countable. Proceeding upward, Cantor called the set of numbers whose predecessors are in one-to-one correspondence with (II) the third number class (III), and so forth. In this way Cantor conceived of ever higher powers as represented by number classes and moreover took every power to be so represented. With this “free creation” of numbers, Cantor then propounded in section 3 of the *Grundlagen* a basic principle that was to drive the analysis of sets:

It is always possible to bring any *well-defined set* into the form of a *well-ordered set*.

He regarded this as a “an especially remarkable law of thought which through its general validity is fundamental and rich in consequences.” Sets are to be well-ordered and thus to be gauged via the transfinite numbers of his structured conception of the infinite.

The transfinite numbers provided the framework for Cantor’s two approaches to the Continuum Problem, one through power and the other through definable sets of real numbers, these each to initiate two vast research programs. As for the first, Cantor in the *Grundlagen* established results that reduced the Continuum Problem to showing that the continuum and the second number class have the same power. However, despite several announcements Cantor could never develop a workable correlation, an emerging problem being that he could not define a well-ordering of the real numbers. As for the approach through definable sets of real numbers, Cantor showed that “CH holds for closed sets.” Closed sets are a very simple kind of definable set of real numbers, and Cantor showed that a closed set either is countable or has the power of the continuum. He thus reduced the Continuum Problem to determining whether there is a closed set of real numbers of the power of the second number class. He could not do this, but he had established the first result of *descriptive set theory*, the definability theory for the continuum.

Almost two decades after his initial 1873 proof, Cantor in a short 1891 note gave his now celebrated *diagonal* argument. He proceeded in terms of functions, ushering in collections of arbitrary functions into mathematics, but we state and prove his result as is done nowadays in terms of the power set $\mathcal{P}(x) = \{y \mid y \subseteq x\}$ of a set x , the collection of all its subsets: *For any set x , $\mathcal{P}(x)$ has a higher power than x .*

First, the function associating each $a \in x$ with $\{a\}$, that subset of x with sole member a , is a one-to-one correspondence between x and a subset of $\mathcal{P}(x)$. Assume now to the contrary that there is a one-to-one correspondence F established between the members of x and all the members of $\mathcal{P}(x)$. Consider the “diagonal” set $d = \{a \mid a \in x \text{ and } a \notin F(a)\}$ consisting of those members a of x that do not belong to their corresponding subset $F(a)$. If d itself were a value of F , say $d = F(b)$ for some $b \in x$, then we would have the paradigmatic contradiction: $b \in d$ exactly when $b \notin d$. Hence, F was not a one-to-one correspondence after all!

Cantor had been shifting his notion of set to a level of abstraction beyond sets of real numbers and the like, and the casualness of his 1891 note may reflect an underlying cohesion with his earlier 1873 argument. Indeed the diagonal argument can be drawn out of the earlier argument, and the new result generalized the old since, with N the set of natural numbers, $\mathcal{P}(N)$ is in one-to-one correspondence with the continuum. With his new result Cantor affirmed that the powers of well-defined sets have no maximum, and he had proved for the first time that there is a power greater than that of the continuum. However, with his view that every well-defined set is well-ordered Cantor would now have had to confront, in his arbitrary function context, a general difficulty starkly abstracted from the Continuum Problem: *From a well-ordering of a set a well-ordering of its power set is not necessarily definable.* The diagonal proof called into question Cantor’s very notion of set.

Cantor’s *Beiträge*, published in two parts in 1895 and 1897, presented his mature theory of the transfinite. In the first part Cantor reconstrued power as *cardinal number*, an autonomous concept beyond being *une façon de parler* about one-to-one correspondence. He defined the addition, multiplication, and exponentiation of cardinal numbers primordially in terms of set-theoretic operations and functions. As befits the introduction of new numbers Cantor then introduced a new notation, one using the Hebrew letter aleph, \aleph . With \aleph_0 the cardinal number of the set of natural numbers Cantor showed that

$$\aleph_0 \cdot \aleph_0 = \aleph_0 \text{ and } 2^{\aleph_0} \text{ is the cardinal number of the continuum}$$

(and hence of $\mathcal{P}(N)$). With this he observed that the 1878 labor of associating the continuum with the plane and so forth could be reduced to a “few strokes of the pen” in his new arithmetic. Cantor only mentioned

$$\aleph_0, \aleph_1, \aleph_2, \dots, \aleph_\omega, \dots,$$

these to be the cardinal numbers of the successive number classes from the *Grundlagen* and thus to exhaust all the infinite cardinal numbers.

Cantor then developed his theory of *order types*, “types” or abstractions of linear orderings. He defined the addition and multiplication of order types and characterized the order types of the rational numbers and of the real numbers. In the second *Beiträge* Cantor turned to the special case of well-orderings and reconstrued the transfinite numbers as their order types, newly calling the numbers the *ordinal numbers*. He then established their basic comparability properties by showing that given two well-orderings one is isomorphic to an initial segment of the other or vice versa. In this new setting he concentrated on the countable ordinal numbers, the new construal of the second number class, and provided an incisive structural analysis in terms of a new operation of ordinal exponentiation.

The two parts of the *Beiträge* were not only distinct by subject matter, cardinal number and the continuum vs. ordinal number and well-ordering, but also between them there developed a wide, insurmountable breach. In the first part nowhere is the 1891 result stated even in a special case, though it was now possible to express it as $\mathfrak{m} < 2^{\mathfrak{m}}$ for any cardinal number \mathfrak{m} , since in his arithmetic

$2^{\mathfrak{m}}$ is the cardinal number of the power set of a set with cardinal number \mathfrak{m} .

Also, the second *Beiträge* does not mention any aleph beyond \aleph_1 , nor does it mention the Continuum Hypothesis, which could have been stated as $2^{\aleph_0} = \aleph_1$. Every well-ordered set, through a corresponding ordinal number, has an aleph as its cardinal number, but how does 2^{\aleph_0} fit into the aleph sequence?

Thus the Continuum Problem was embedded in the very interstices of the early development of set theory, and in fact the structures that Cantor built, while now of great intrinsic interest, emerged out of efforts to articulate and solve the Continuum Problem. The tension uncovered by Cantor’s diagonal argument between well-ordering and power set (or arbitrary functions) would soon be revisited by Zermelo. David Hilbert, when he presented his famous list of twenty-three problems at the 1900 International Congress of Mathematicians at Paris, made the Continuum Problem the very first problem and intimated Cantor’s difficulty by suggesting the desirability of “actually giving” a well-ordering of the real numbers.

At the turn into the twentieth century the “logical” limits of set formation and existence were broached for sets being counterparts to “concepts” or properties. In correspondence with Hilbert and Richard Dedekind in the late 1890s Cantor became newly engaged with questions of set existence. He had earlier considered collections like all ordinal numbers or all alephs as leading out of his conceptual framework. These “absolutely infinite or inconsistent multiplicities,” if admitted as sets, would lead to contradictions, and Cantor argued anew that every set can be well-ordered else it would in one-to-one correspondence with all the ordinal numbers and hence an inconsistent multiplicity. In this he anticipated later developments in set theory.

Bertrand Russell, a main architect of the analytic tradition in philosophy, focused in 1900 on Cantor’s work. Russell was pivoting from idealism toward logicism, the thesis that mathematics can be founded in logic. Taking a universalist approach to logic with all-encompassing categories, Russell took the class of all classes to have the largest cardinal number but saw that Cantor’s 1891 result leading to higher cardinal numbers presented a problem. Analyzing that argument, by the spring of 1901 he arrived at the famous *Russell’s Paradox*. This paradox showed with remarkable simplicity that there are properties $P(x)$ such that the collection of objects having that property, the *class*

$$\{x \mid P(x)\},$$

cannot itself be an object: Consider $\{x \mid x \notin x\}$. If this were an object r in the range of possibilities, then we would have the contradiction $r \in r$ exactly when $r \notin r$. This paradox may have been critical for Russell’s universalist approach to logic and for logicism, but it was less so for the development of set theory, which was emerging in mathematics. In any case the paradox did serve as a motivation for fashioning a consistent notion of set through axiomatization.

The first decade of the new century saw Zermelo make his major advances in the development of set theory. Already estimable as an applied mathematician, Zermelo turned to set theory and its foundations under the influence of Hilbert. Zermelo’s first substantial result was his independent discovery of the argument for Russell’s Paradox. He then established in 1904 the Well-Ordering Theorem, that every set can be well-ordered, assuming what he soon called the Axiom of Choice (AC). Zermelo thereby shifted the notion of set away from the implicit assumption of Cantor’s principle that every well-defined

set is well-ordered and replaced that principle by an explicit axiom about a wider notion of set.

In retrospect Zermelo's *argument* for his Well-Ordering Theorem can be viewed as pivotal for the development of set theory. To summarize the argument, suppose that x is a set to be well-ordered, and through Zermelo's Axiom-of-Choice hypothesis assume that the power set $\mathcal{P}(x) = \{y \mid y \subseteq x\}$ has a choice function, that is, a function γ such that for every non-empty member y of $\mathcal{P}(x)$, $\gamma(y) \in y$. Call a subset y of x a γ -set if there is a well-ordering R of y such that for each $a \in y$,

$$\gamma(\{z \mid z \notin y \text{ or } z R a \text{ fails}\}) = a.$$

That is, each member of y is what γ "chooses" from what does not already precede that member according to R . The main observation is that γ -sets cohere in the following sense: If y is a γ -set with well-ordering R and z is a γ -set with well-ordering S , then $y \subseteq z$ and S is a prolongation of R , or vice versa. With this, let w be the union of all the γ -sets, that is, all the γ -sets put together. Then w too is a γ -set, and by its maximality it must be all of x and hence x is well-ordered.

Note that the converse to this result is immediate in that if x is well-ordered, say with a well-ordering $<$, then the power set $\mathcal{P}(x)$ has a choice function δ , namely for each non-empty member y of $\mathcal{P}(x)$, let $\delta(y)$ be the the $<$ -least member of y . Not only did Zermelo's argument analyze the connection between well-ordering and choice functions, but it anticipated in its defining of approximations and taking of a union the proof procedure for von Neumann's Transfinite Recursion Theorem.

Zermelo maintained that the Axiom of Choice, to the effect that *every* set has a choice function, is a "logical principle" which "is applied without hesitation everywhere in mathematical deduction," and this is reflected in the Well-Ordering Theorem being regarded as a theorem. Cantor's work had served to exacerbate a growing discord among mathematicians with respect to two related issues: whether infinite collections can be mathematically investigated at all, and how far the function concept is to be extended. The positive use of an arbitrary function operating on arbitrary subsets of a set having been made explicit, there was open controversy after the appearance of Zermelo's proof. This can be viewed as a turning point for mathematics, with the subsequent tilting toward the acceptance of the Axiom of Choice symptomatic of a conceptual shift in mathematics.

AXIOMATIZATION

In response to his critics Zermelo published a second proof of the Well-Ordering Theorem in 1908, and with axiomatization assuming a general methodological role in mathematics he also published in 1908 the first full-fledged axiomatization of set theory. But as with Cantor's work, this was no idle structure building but a response to pressure for a new mathematical context. In this case it was not for the formulation and solution of a *problem* like the Continuum Problem, but rather to clarify a *proof*. Zermelo's motive in large part for axiomatizing set theory was to buttress his Well-Ordering Theorem by making explicit its underlying set existence assumptions. Effecting the first transmutation of the notion of set after Cantor, Zermelo ushered in a new abstract, prescriptive view of sets as solely structured by membership and governed by axioms, a view that would soon come to dominate.

The following are Zermelo's axioms, much as they would be presented today. They are to govern the connections between \in and \subseteq and to prescribe the generation of new sets out of old. The standard axiomatization would be the result of adding two further axioms and formalizing in first-order logic.

AXIOM OF EXTENSIONALITY. *Two sets are equal exactly when they have the same members.* Thus sets epitomize the *extensional* view of mathematics, it being stipulated that however sets are arrived at, there is a definite criterion for equality provided solely by membership.

AXIOM OF EMPTY SET. *There is a set having no members.* This axiom serves to emphasize the beginning with an initial set, the *empty* set, denoted \emptyset .

AXIOM OF PAIRS. *For any sets x and y , there is a set consisting of exactly x and y as members.* The posited set is denoted $\{x, y\}$ and is called the (unordered) pair of x and y . $\{x, x\}$ is denoted $\{x\}$, as we have already seen, and is called the *singleton* of x .

AXIOM OF UNION. *For any set x , there is a set consisting exactly of those sets that are members of some member of x .* The posited set is denoted $\cup x$ and is called the *union* of x . This "generalized" union subsumes the better known binary union, in that for any sets a and b ,

$$a \cup b = \cup \{a, b\} = \{x \mid x \in a \text{ or } x \in b\}.$$

If a set x is structured as an indexed set $\{x_i \mid i \in I\}$, then $\cup x$ is often written as $\cup_{i \in I} x_i$ or just $\cup x_i$.

AXIOM OF POWER SET. For any set x , there is a set consisting exactly of the subsets of x . The posited set is denoted $\mathcal{P}(x)$ and is called the *power set* of x , as we have already seen.

AXIOM OF CHOICE. For any set x consisting of non-empty, pairwise disjoint sets, there is a set c such that every member of x has exactly one element in c . Thus, c acts like a choice function for x construed as a family of sets. This is a reductive way of positing choice functions.

AXIOM OF INFINITY. There is a set having \emptyset as a member and such that whenever y is a member, so also is $y \cup \{y\}$. This has become the usual way of positing the existence of an infinite set, in light of the definition of ordinals. Zermelo actually stated his axiom with “ $y \cup \{y\}$ ” replaced by “ $\{y\}$,” getting at a set describable informally as $\{\emptyset, \{\emptyset\}, \{\{\emptyset\}\}, \dots\}$.

AXIOM OF SEPARATION. For any set x and definite property P , there is a set consisting exactly of those members of x having the property P . Once a collection has been comprehended as a set, we are able to form a subset by “separating” out according to a property. Or, a subclass of a set is a set. Taking the property of being a member of a given set a , we have as a set the binary intersection

$$x \cap a = \{y \mid y \in x \text{ and } y \in a\}.$$

Taking the property of not being a member of a , we have as a set the set-theoretic difference

$$x - a = \{y \mid y \in x \text{ and } y \notin a\}.$$

As a further use of the axiom, consider for a set x the *intersection* of x :

$$\cap x = \{a \mid a \in y \text{ for every } y \in x\}.$$

This is a (property-specifiable) subclass of any member of x , and so we have as a theorem: *If $x \neq \emptyset$ then $\cap x$ is a set.* This is a “generalized” intersection, with the better known binary intersection being $\cap \{x, a\} = x \cap a$.

According to Zermelo a property is “definite if the fundamental relations of the domain, by means of the axioms and the universally valid laws of logic, determine without arbitrariness whether it holds or not.” But with no underlying logic formalized, the ambiguity of definite property would become a major issue, one that would eventually be resolved only decades later through first-order formalization. In any case Zermelo saw that the Separation idea suffices for a development of set theory that still allows for the “logical” formation of sets accord-

ing to property. Russell’s Paradox is forestalled since only “logical” subsets are to be allowed; indeed, Zermelo’s first theorem was that there is no universal set, a set that contains every set as a member, the *reductio* argument being the paradox argument.

Stepping back, Extensionality, Empty Set, and Pairs served to lay the basis for sets. Infinity and Power Set ensured sufficiently rich settings for set-theoretic constructions. Tempering the logicians’ extravagant and problematic “all,” Power Set provided the provenance for “all” for subsets of a given set, just as Separation served to capture “all” for elements of a given set satisfying a property. Finally, Union and Choice completed the encasing of Zermelo’s proof(s) of his Well-Ordering Theorem in the necessary set existence principles.

Although Hilbert’s axiomatization of geometry in his 1899 *Grundlagen der Geometrie* may have served as a model for Zermelo’s axiomatization of set theory and Dedekind’s 1888 essay *Was sind und was sollen die Zahlen?* on the foundations of arithmetic a precursor, there are crucial differences having to do with subject matter and proof. Both in intent and outcome Dedekind and Hilbert had been engaged in the analysis of fixed subject matter. Dedekind in particular had done a great deal to enshrine proof as the vehicle for algebraic abstraction and generalization. Like algebraic constructs, sets were new to mathematics and would be incorporated by setting down rules for their proofs. Just as Euclid’s axioms for geometry had set out the permissible geometric constructions, the axioms of set theory would set out rules for set generation and manipulation. But unlike the emergence of mathematics from marketplace arithmetic and Greek geometry, sets and transfinite numbers were neither laden with nor bolstered by substantial antecedents. There was no fixed, intended subject matter. Like strangers in a strange land stalwarts developed a familiarity with sets guided step by step by the axiomatic framework. For Dedekind it had sufficed to work with sets by merely giving a few definitions and properties, those foreshadowing Extensionality, Union, and Infinity. Zermelo provided more rules: Separation, Power Set, and Choice.

Zermelo’s 1908 axiomatization paper, especially with its rendition at the end of the Cantorian theory of cardinality in terms of functions cast as set constructs, brought out Zermelo’s *set-theoretic reductionism*. Zermelo pioneered the reduction of mathematical concepts and arguments to set-theoretic concepts and arguments from axioms, based on sets doing the work of mathematical objects. Set theory would provide the underpinnings of mathematics, and Zermelo’s axioms would resonate with

emerging mathematical practice. Zermelo's analysis moreover served to draw what would come to be generally regarded as set-theoretic out of the realm of the presumptively logical. This would be particularly salient for Infinity and Power Set and was strategically advanced by the segregation of property considerations to Separation. Based on generative and prescriptive axioms, set theory would become more combinatorial, less logical. With these features Zermelo's axioms indeed proved more than adequate to serve as a reductive basis for mathematics, at least for providing surrogates for mathematical objects; looking ahead it was for subsequent developments to bring out that set theory could also serve as a court of adjudication in terms of relative consistency.

Felix Hausdorff was the first developer of the transfinite after Cantor, the one whose work first suggested the rich possibilities for a mathematical investigation of the higher transfinite. A mathematician *par excellence* Hausdorff took the sort of mathematical approach to set theory and set-theoretic approach to mathematics which would come to dominate in the years to come. In a 1908 publication Hausdorff brought together his extensive work on *uncountable* order types, and in particular formulated the *Generalized Continuum Hypothesis* (GCH): For any infinite set x , there is no set of cardinal number strictly intervening between that of x and of its power set $\mathcal{P}(x)$; or in Cantor's later terms, for every ordinal number α , $2^{\aleph_\alpha} = \aleph_{\alpha+1}$. Hausdorff also entertained for the first time a "large cardinal" concept, of which more below. Hausdorff's classic 1914 text, *Grundzüge der Mengenlehre*, broke the ground for a generation of mathematicians in both set theory and topology. He presented Cantor's and Zermelo's work systematically, and of particular interest, he applied the Axiom of Choice to provide what is now known as Hausdorff's Paradox. The source of the later and better known Banach-Tarski Paradox, Hausdorff's Paradox provided an implausible decomposition of the sphere and was the first, and a dramatic, synthesis of classical mathematics and the new Zermelian abstract view.

In the *Grundzüge* Hausdorff defined an ordered pair of sets in terms of (unordered) pairs, formulated functions in terms of ordered pairs, and ordering relations as collections of ordered pairs. Hausdorff thus capped efforts of logicians by making their moves in mathematics, completing the set-theoretic reduction of relations and functions. In the modern setting, the definition of the ordered pair that has been adopted is not Hausdorff's, but one provided by Kazimierz Kuratowski in 1921:

$$\langle x, y \rangle = \{\{x\}, \{x, y\}\}.$$

This satisfies all that is operationally required of an ordered pair:

$$\langle x, y \rangle = \langle a, b \rangle \text{ exactly when } x = a \text{ and } y = b.$$

With this definition, a set r is a *relation* if it consists of ordered pairs. This objectification is often eased by reverting to the older conceptual notation $a r b$ for $\langle a, b \rangle \in r$. A set f is a *function* if it is a relation satisfying: If $\langle x, y \rangle \in f$ and $\langle x, z \rangle \in f$, then $y = z$. This objectification is eased by reverting to the older operational notation $f(x) = y$ for $\langle x, y \rangle \in f$, though the emphasis is on the generality and arbitrariness of f as just a relation with a univalency property. Finally the dynamic notation $f: a \rightarrow b$ specifies that f is a function such that every member of a is a first coordinate of an ordered pair in f , and that every second coordinate is a member of b .

AXIOMATIZATION COMPLETED

In the 1920s fresh initiatives structured the loose Zermelian framework with new features and corresponding developments in axiomatics, the most consequential moves made by John von Neumann with anticipations by Dimitry Mirimanoff in a pre-axiomatic setting. Von Neumann effected a Counter-Reformation of sorts that led to the incorporation of a new axiom, the Axiom of Replacement: The transfinite numbers had been central for Cantor but peripheral to Zermelo; von Neumann reconstrued them as *bona fide* sets, the ordinals, and established their efficacy by formalizing transfinite recursion, the method of sequential definition of sets based on previously defined sets applied with transfinite indexing.

Ordinals manifest the basic idea of taking precedence in a well-ordering simply to be membership:

Definitions. A set x is *transitive* if $\cup x \subseteq x$, that is, whenever $a \in b$ and $b \in x$, then $a \in x$.

A set x is a (von Neumann) *ordinal* if x is transitive and the membership relation restricted to $x = \{y \mid y \in x\}$ is a well-ordering of x .

For example, \emptyset is transitive, but $\{\{\emptyset\}\}$ is not. Loosely speaking, transitive sets retain all their hereditary members. The first several ordinals are

$$\emptyset, \{\emptyset\}, \{\emptyset, \{\emptyset\}\}, \{\emptyset, \{\emptyset, \{\emptyset, \{\emptyset\}\}\}, \dots$$

and are newly taken to be the numbers 0, 1, 2, 3, If x is an ordinal, then so also is $x \cup \{x\}$, the *successor* of x , and this accounts for how the Axiom of Infinity was formulated in the previous section. It has become customary to use the Greek letters $\alpha, \beta, \gamma, \dots$ to denote ordinals. Von

Neumann, as had Mirimanoff before him, established the key instrumental property of Cantor's ordinal numbers for ordinals: *Every well-ordered set is order-isomorphic to exactly one ordinal with membership*. The proof made a paradigmatic use of Replacement, and so was the first proof to draw that axiom into set theory.

For a set x and property $P(v, w)$, the property is said to be *functional on x* if for any $a \in x$, there is exactly one b such that $P(a, b)$.

AXIOM OF REPLACEMENT. For any set x and property $P(v, w)$ functional on x , $\{b \mid P(a, b) \text{ for some } a \in x\}$ is a set.

This axiom allows for new sets that result when members of a set are "replaced" according to a property. If the functional property is given by a set, that is there is a function f , a set of ordered pairs, such that $P(v, w)$ exactly when $f(v) = w$, then Replacement is not needed. However, as in the case of the above-stated result correlating arbitrary well-orderings with ordinals, there are functional properties that are more general, typically formulated by recursion.

Replacement subsumes Separation. Suppose that x is a set and P is a (definite) property. If there are no members of x satisfying P , then we are done. Otherwise, fix such a member y_0 . For any $a \in x$, let $P(a, a)$ hold if a satisfies P and $P(a, y_0)$ hold otherwise. Then the "replaced" set $\{b \mid P(a, b) \text{ for some } a \in x\}$ is the set of members of x satisfying P .

Von Neumann took the crucial step of ascribing to the ordinals the role of Cantor's ordinal numbers with their several principles of generation. Now, with ordinal numbers regarded as gauging well-orderings, that one is isomorphic to a proper initial part of another corresponds for ordinals to actual membership and can be rendered

$$\alpha < \beta \text{ exactly when } \alpha \in \beta.$$

For this reconstrual of ordinal numbers and already to define the arithmetic of ordinals von Neumann saw the need to establish the Transfinite Recursion Theorem, the theorem that validates definitions by recursion along well-orderings. The proof was anticipated by the Zermelo 1904 proof, but Replacement was necessary even for the very formulation, let alone the proof, of the theorem. With the ordinals in place von Neumann completed the restoration of the Cantorian transfinite by defining the *cardinals* as the *initial ordinals*, those ordinals not in one-to-one correspondence with any of its predecessors. The infinite initial ordinals are denoted

$$\omega = \omega_0, \omega_1, \omega_2, \dots, \omega_\alpha, \dots,$$

so that ω is to be the set of natural numbers in the ordinal construal, and the identification of different intentions is signaled by

$$\omega_\alpha = \aleph_\alpha$$

with the left being a von Neumann ordinal and the right being the Cantorian cardinal number. Every set x , with AC, is well-orderable and hence in one-to-one correspondence with an initial ordinal ω_α , and the *cardinality* of x is $|x| = \aleph_\alpha$. It has become customary to use the middle Greek letters $\kappa, \lambda, \mu, \dots$ to denote initial ordinals in their role as the cardinals. A *successor* cardinal is one of form $\aleph_{\alpha+1}$ and is denoted κ^+ for $\kappa = \aleph_\alpha$. A cardinal which is not a successor cardinal is a *limit* cardinal.

Replacement has been latterly regarded as somehow less necessary or crucial than the other axioms, the purported effect of the axiom being only on large-cardinality sets. Initially Abraham Fraenkel and Thoralf Skolem had independently in 1922 proposed the addition of Replacement to Zermelo's axioms, both pointing out the inadequacy of Zermelo's axioms for establishing that $E = \{Z_0, \mathcal{P}(Z_0), \mathcal{P}(\mathcal{P}(Z_0)), \dots\}$ is a set, where $Z_0 = \{\emptyset, \{\emptyset\}, \{\{\emptyset\}\}, \dots\}$ is Zermelo's infinite set from his Axiom of Infinity. However even $F = \{\emptyset, \mathcal{P}(\emptyset), \mathcal{P}(\mathcal{P}(\emptyset)), \dots\}$ cannot be proved to be a set from Zermelo's axioms: The union of E above, with membership restricted to it, models Zermelo's axioms yet does not have F as a member. Hence Zermelo's axioms cannot establish the existence of some simple countable sets consisting of finite sets and could be viewed as remarkably lacking in closure under finite recursive processes. If the Axiom of Infinity were itself modified to entail that F is a set, then there would still be many other finite sets a so that $\{a, \mathcal{P}(a), \mathcal{P}(\mathcal{P}(a)), \dots\}$ cannot be proved to be a set. Replacement serves to rectify the situation by allowing new infinite sets defined by "replacing" members of the one infinite set given by the Axiom of Infinity. In any case the full exercise of Replacement is part and parcel of transfinite recursion, and it was von Neumann's formal incorporation of this method into set theory, as necessitated by his proofs, that brought in Replacement.

Von Neumann (and before him Mirimanoff, Fraenkel, and Skolem) also considered the salutary effects of restricting the universe of sets to the well-founded sets. The *well-founded* sets are the sets that belong to some "rank" V_α , these definable through transfinite recursion:

$$V_0 = \emptyset; V_{\alpha+1} = \mathcal{P}(V_\alpha); \text{ and } V_\delta = \bigcup \{V_\alpha \mid \alpha < \delta\} \text{ for limit ordinals } \delta.$$

V_ω consists of the “hereditarily finite” sets, $\omega \in V_{\omega+1}$ and $\mathcal{P}(\omega) \in V_{\omega+2}$, and so already in these beginning levels there are set counterparts for many objects in mathematics. That the universe V of all sets is the *cumulative hierarchy*

$$V = \cup \{V_\alpha \mid \alpha \text{ is an ordinal}\}.$$

is thus the assertion that every set is well-founded. Von Neumann essentially showed that this assertion is equivalent to a simple assertion about sets:

AXIOM OF FOUNDATION. $\forall x(x \neq \emptyset \rightarrow \exists y \in x (x \cap y = \emptyset)).$

Thus non-empty well-founded sets have \in -minimal members. If a set x satisfies $x \in x$ then $\{x\}$ is not well-founded; similarly if there are $x_1 \in x_2 \in x_1$, then $\{x_1, x_2\}$ is not well-founded. Ordinals and sets consisting of ordinals are well-founded, and well-foundedness can be viewed as a generalization of being an ordinal that loosens the connection with transitivity. The Axiom of Foundation eliminates pathologies like $x \in x$ and through the cumulative hierarchy rendition provides metaphors about building up the universe of sets and the possibility of inductive arguments to establish results about all sets.

In a remarkable 1930 publication Zermelo offered his final axiomatization of set theory as well as a striking, synthetic view of a procession of models that would have a modern resonance. Proceeding in what we would now call a second-order context, Zermelo extended his 1908 axiomatization by adjoining both Replacement and Foundation. The standard axiomatization of set theory

ZFC, *Zermelo-Fraenkel with Choice*,

is recognizable, the main difference being that ZFC is a first-order theory (see the next section); “Fraenkel” acknowledges Fraenkel’s suggestion of adjoining Replacement; and the Axiom of Choice is explicitly mentioned.

ZF, *Zermelo-Fraenkel*,

is ZFC without AC and is a base theory for the investigation of weak Choice-type propositions as well as propositions that contradict AC.

Zermelo herewith completed his transmutation of the notion of set, his abstract, prescriptive view stabilized by further axioms that structured the universe of sets. Replacement and Foundation focused the notion of set, with the first providing the means for transfinite recursion and induction, and the second making possible the application of those means to get results about *all* sets. It

is nowadays almost banal that Foundation is the one axiom unnecessary for the recasting of mathematics in set-theoretic terms, but the axiom is also the salient feature that distinguishes investigations specific to set theory as an autonomous field of mathematics. Indeed it can be fairly said that modern set theory is at base a study couched in well-foundedness, the Cantorian well-ordering doctrines adapted to the Zermelian generative and prescriptive conception of sets. With Replacement and Foundation in place, Zermelo was able to provide natural models of his axioms and to establish algebraic isomorphism, initial segment, and embedding results for his models. Finally Zermelo posited an endless procession of his models, each a set in the next, as natural extensions of their cumulative hierarchies.

Zermelo found a simple set-theoretic condition, being an inaccessible cardinal, that characterizes the ordinal heights of his models, that is those ordinals ρ such that the predecessors of ρ are exactly the ordinals of a model.

Definitions. An infinite cardinal κ is *singular* if there is an $x \subseteq \kappa$ of smaller cardinality than κ which is cofinal in κ , that is to say for any $\alpha < \kappa$ there is a $\beta \in x$ with $\alpha \leq \beta$. An infinite cardinal which is not singular is *regular*

An infinite cardinal κ is a *strong limit* if for any cardinal $\beta < \kappa$, $2^\beta < \kappa$.

An infinite cardinal κ is *inaccessible* if it is both regular and a strong limit.

\aleph_0 is regular; \aleph_1 , \aleph_2 , ... and generally, all successor cardinals are regular. The limit cardinal \aleph_ω is singular, since it has a countable cofinal subset $\{\aleph_0, \aleph_1, \aleph_2, \dots\}$. Hausdorff in 1908 had initially entertained the possibility of having a regular limit cardinal. Inaccessible cardinals had later been considered to be a stronger version that arithmetically incorporated power sets, but Zermelo provided the first structural rationale for them, as the delimiters of his natural models.

Inaccessible cardinals are the modest beginnings of the theory of *large cardinals*, a mainstream of modern set theory devoted to the investigation of strong hypotheses and consistency strength. Large cardinal hypotheses posit structure in the higher reaches of the cumulative hierarchy, most often by positing cardinals that prescribe their own inaccessible transcendence over smaller cardinals, and were seen by the 1970s to form a natural hierarchy of stronger and stronger propositions transcending ZFC.

The journal volume containing Zermelo’s 1930 publication also contained Stanisław Ulam’s seminal paper on *measurable cardinals*, which became the most pivotal

of all large cardinals. For a set s , U is a (non-principal) *ultrafilter over s* if U is a collection of subsets of s containing no singletons; if $x \in U$ and $x \subseteq y \subseteq s$, then $y \in U$; if $x \in U$ and $y \in U$, then $x \cap y \in U$; and for any $x \subseteq s$, either $x \in U$ or $s - x \in U$. For a cardinal λ , an ultrafilter U is λ -*complete* if for any $D \subseteq U$ of cardinality less than λ , $\bigcap D \in U$. Finally an uncountable cardinal κ is *measurable* if there is a κ -complete ultrafilter over κ . Thus, a measurable cardinal is a cardinal whose power set is structured with a two-valued “measure” having a strong closure property. Measurability embodied the first large cardinal confluence of Cantor’s two legacies, the investigation of definable sets of reals and the extension of number into the transfinite: The concept was distilled from measure-theoretic considerations related to Lebesgue’s measure for sets of real numbers, and it also entailed inaccessibility in the transfinite.

FORMALIZATION AND MODEL-THEORETIC METHODS

Zermelo’s 1930 publication was in part a response to Skolem’s 1922 advocacy of the idea of framing Zermelo’s 1908 axioms in first-order logic. First-order logic investigates the logic of formal languages consisting of formulas built up from specified function and predicate symbols using logical connectives and first-order quantifiers \forall and \exists , these interpreted as ranging over the *elements* of a domain of discourse. (Second-order logic has quantifiers interpreted as ranging over properties, or collections of elements.) First-order logic had emerged in the 1917 lectures of Hilbert as a delimited system of logic potentially amenable to mathematical analysis. Entering from a different, algebraic tradition Skolem had established a seminal result for “metamathematical” methods with the Löwenheim-Skolem Theorem: *If a countable collection of first-order sentences has a model then it has a countable model.*

For set theory Skolem proposed formalizing Zermelo’s axioms in the first-order language with \in and $=$ as binary predicate symbols. Zermelo’s *definite* properties were to be those expressible in this first-order language in terms of given sets, and the Axiom of Separation was to become a schema of axioms, one for each first-order formula that has variables allowing for set parameters. As a palliative for taking set theory as a foundation for mathematics, Skolem then pointed out what has come to be called the *Skolem Paradox*: Zermelo’s 1908 axioms cast in first-order logic is a countable collection of sentences, and so if they have a model at all, they have a countable model. (Analogous remarks apply to the latterly adjoined

Axiom of Replacement becoming a schema.) Thus we have the paradoxical existence of countable models for Zermelo’s axioms although they entail the existence of uncountable sets. Zermelo found this antithetical and repugnant. However stronger currents were at work, leading to a further, subtler transmutation of the notion of set mediated by first-order logic and incorporating its relativism of set-theoretic concepts.

Gödel virtually completed the mathematization of logic by submerging metamathematical methods into mathematics. The main vehicle was the direct coding, “the arithmetization of syntax,” in his celebrated 1931 Incompleteness Theorem, which worked dialectically against a program of Hilbert’s for establishing the consistency of mathematics. But starting an undercurrent, the earlier 1930 Completeness Theorem for first-order logic clarified the distinction between the formal syntax and semantics (interpretations) of first-order logic, and secured its key instrumental property with the Compactness Theorem: *If a collection of first-order sentences is such that every finite subcollection has a model, then the whole collection has a model.*

Gödel’s work showed that the notion of the consistency of a mathematical theory has a formal counterpart expressible in the first-order language with function symbols for addition and multiplication. Loosely speaking, a *theory* is a collection of sentences of some first-order language; that a sequence of formulas constitutes a *deduction* can be formalized; and a theory is *consistent* if from it no contradiction can be derived. Gödel’s arithmetization of syntax codes all this into statements about the natural numbers and their arithmetic, yielding a formula

$$\text{Con}(T)$$

asserting the formal consistency of T , at least for those theories whose sentences can be schematically defined. Gödel famously established through his Incompleteness Theorem that for consistent theories subsuming the arithmetic of the natural numbers, $\text{Con}(T)$ itself cannot be deduced from T . However, one may be able to deduce relative notions:

Definitions. A sentence σ is *relatively consistent* with a theory T if $\text{Con}(T)$ implies $\text{Con}(T + \sigma)$.

A sentence σ is *independent* of a theory T if both σ and its negation are relatively consistent with T .

Two sentences σ_1 and σ_2 are *equi-consistent* over a theory T if $\text{Con}(T + \sigma_1)$ is equivalent to $\text{Con}(T + \sigma_2)$.

These assertions would be established over a weak base theory. For example, in the parlance, that a set-theoretic statement σ is relatively consistent with set theory generally means that $\text{Con}(\text{ZFC})$ implies $\text{Con}(\text{ZFC} + \sigma)$, this itself deducible in (some weak version of) ZFC. *Consistency strength* in set theory can be discussed in these terms, typically for strong set theoretic statements not provable from ZFC: For two set-theoretic statements σ_1 and σ_2 , the consistency strength of σ_1 is least that of σ_2 if $\text{Con}(\text{ZFC} + \sigma_1)$ implies $\text{Con}(\text{ZFC} + \sigma_2)$, and so σ_1 and σ_2 have equal consistency strength if σ_1 and σ_2 are equi-consistent over ZFC.

Tarski in the early 1930s completed the mathematization of logic by providing his “definition of truth,” exercising philosophers to a surprising extent ever since. Tarski simply schematized truth as a correspondence between formulas of a formal language and set-theoretic assertions about an interpretation of the language and provided a recursive definition of the *satisfaction* relation, when a formula holds in an interpretation, in set-theoretic terms. This response to a growing need for a mathematical framework became the basis for *model theory*. The eventual effect of Tarski’s mathematical formulation of semantics would be not only to make mathematics out of the informal notion of satisfiability, but also to enrich ongoing mathematics with a systematic method for forming mathematical analogues of several intuitive semantic notions. For coming purposes, the following specifies notation and concepts in connection with Tarski’s definition:

Definitions. For a first-order language, an interpretation N of that language (i.e., a specification of a domain of discourse as well as interpretations of the function and predicate symbols), a formula $\varphi(v_1, v_2, \dots, v_n)$ of the language with the variables as displayed, and a_1, a_2, \dots, a_n in the domain of N ,

$$N \models \varphi[a_1, a_2, \dots, a_n]$$

asserts that the formula φ is satisfied in N according to Tarski’s recursive definition when v_i is interpreted as a_i .

A subset y of the domain of N is *first-order definable over* N if there is a formula $\psi(v_0, v_1, v_2, \dots, v_n)$ and a_1, a_2, \dots, a_n in the domain of N such that

$$y = \{z \mid N \models \psi[z, a_1, \dots, a_n]\}.$$

Set theory was launched on an independent course as a distinctive field of mathematics by Gödel’s formulation of the model L of “constructible” sets, with which he established the relative consistency of the Axiom of

Choice (AC) and the Generalized Continuum Hypothesis (GCH). L is a transitive class containing all the ordinals that, with the membership relation restricted to it, satisfies each axiom of ZFC as well as GCH. Through L Gödel established that $\text{Con}(\text{ZF})$ implies $\text{Con}(\text{ZFC} + \text{GCH})$ and thus attended to fundamental issues at the beginnings of set theory. In his first, 1938 announcement Gödel described L as a hierarchy “which can be obtained by Russell’s ramified hierarchy of types, if extended to include transfinite orders.” Indeed with L Gödel had refined the cumulative hierarchy of sets to a cumulative hierarchy of *definable* sets which is analogous to the orders of Russell’s *ramified* theory. Gödel’s further innovation was to continue the indexing of the hierarchy through *all* the (von Neumann) ordinals to get a model of set theory. In a 1939 note Gödel presented L essentially as it is presented today: For any set x let $\text{def}(x)$ denote the collection of subsets of x first-order definable over x according to the previous definition. Then define:

$$L_0 = \emptyset; L_{\alpha+1} = \text{def}(L_\alpha), L_\delta = \bigcup\{L_\alpha \mid \alpha < \delta\} \\ \text{for limit ordinals } \delta;$$

and the *constructible universe*

$$L = \bigcup\{L_\alpha \mid \alpha \text{ is an ordinal}\}.$$

Gödel brought into set theory a method of construction and argument and thereby affirmed several features of its axiomatic presentation. First Gödel showed that $\text{def}(x)$ and generally first-order definability over set domains is itself definable in set theory, so that in particular the definition of L can be effected in set theory via transfinite recursion. This significantly contributed to a lasting ascendancy for first-order logic which beyond its *sufficiency* as a logical framework for mathematics was seen to have considerable *operational efficacy*. Gödel’s construction moreover buttressed the incorporation of Replacement and Foundation into set theory. Replacement was immanent in the arbitrary extent of the ordinals for the indexing of L and in its formal definition via transfinite recursion. As for Foundation, underlying the construction was the well-foundedness of sets, and significantly, Gödel viewed L as deriving its contextual sense from the cumulative hierarchy of sets regarded as an extension of the *simple* theory of types. In footnote 12 of his 1939 note he wrote, “In order to give A [that $V = L$] an intuitive meaning, one has to understand by ‘sets’ all objects obtained by building up the simplified hierarchy of types on an empty set of individuals (including types of arbitrary transfinite orders).” Some have been puzzled about how the cumulative hierarchy picture emerged in set-theoretic practice; although there was Mirimanoff,

von Neumann, and especially Zermelo, the picture came in with Gödel's method, the reasons being both thematic and historical: Gödel's work with L with its incisive analysis of first-order definability was readily recognized as a signal advance, while Zermelo (1930) with its second-order vagaries remained somewhat obscure. As the construction of L was gradually digested, the sense that it promoted of a cumulative hierarchy reverberated to become the basic picture of the universe of sets.

In a notable inversion, what has come to be regarded as the *iterative conception*, the conception of sets as being built up through stages of construction as schematized by the cumulative hierarchy, has become a heuristic for motivating the axioms of set theory generally. This has opened the door to a metaphysical appropriation in the following sense: It is as if there is some notion of set that is "there," in terms of which the axioms must find some further justification. But set theory has no particular obligations to mirror some prior notion of set, especially one like the iterative conception, arrived at *a posteriori*. Replacement and Choice for example do not quite "fit" the iterative conception, but if need be, Replacement can be "justified" in terms of achieving algebraic closure of the axioms, a strong motivation in the work of Fraenkel and the later Zermelo, and Choice can be "justified" as a logical principle as Zermelo had maintained.

Gödel's proof of the GCH in L , like Zermelo's proof of the Well-Ordering Theorem, was synthetic and pivotal for the development of set theory. Gödel actually established that if λ is an infinite cardinal and $x \in L_\lambda$, then for any $y \subseteq x$ in L , $y \in L_\lambda$. The Power Set Axiom was thus tamed in L leading to the relative consistency of GCH. Replacement played a crucial role not only by providing for the prior extent of ordinals, but also in allowing this first instance of model-theoretic reflection. Reflection properties, which in one form came to be seen as equivalent to Replacement, assert that various properties holding at one level of the cumulative hierarchy holds at an earlier level, and they have been a leading heuristic for motivating large cardinals. Gödel's proof also made a specific, positive use of the Skolem Paradox argument, as he used what are now known as *Skolem functions* to take a *Skolem hull*. Paradox became method, affirming the operational efficacy of first-order logic. Finally Gödel took for the first time what is now known as the *transitive collapse*. Andrzej Mostowski would later state in general terms the result, which is a generalization to well-founded relations and transitive sets of the Mirimanoff–von Neumann result, that every well-ordered set is order-isomorphic to exactly one ordinal with membership. While that result

was basic to the analysis of well-orderings, the transitive collapse result grew in significance from specific applications and came to epitomize how well-foundedness made possible a coherent theory of models of set theory.

In all these ways Gödel's work promoted a further transmutation of, or at least a new relativism about, the notion of set as mediated by first-order logic. By the 1950s ZFC was generally taken to be a theory formalized in first-order logic. The relativism of set-theoretic concepts was brought to the fore, as well as new possibilities for constructions of models of set theory. Results even about definable sets of real numbers would turn on contingencies of relative consistency. Notably, Gödel himself held a "Platonistic" conception of set theory as descriptive of an objective universe schematized by the cumulative hierarchy; nonetheless, his work laid the groundwork for the development of a range of models and axioms for set theory.

Gödel's work with L stood as an isolated monument for quite a number of years, World War II no doubt having a negative effect on mathematical progress. On the crest of a new generation Dana Scott established a result in 1961 that would become seminal for the theory of large cardinals. Ultrafilters gained prominence in model theory in the late 1950s because of the emergence of the *ultrapower* and more generally *ultraproduct* construction for building concrete models, when Scott made the crucial move of taking the ultrapower of the universe V itself by an ultrafilter as provided by a measurable cardinal. Such an ultrafilter provided well-founded ultrapowers, and the full exercise of the transitive collapse now led to an inner model M and an elementary embedding $j: V \rightarrow M$.

Definitions. M is an *inner model* if it is a transitive class containing all the ordinals that, with the membership relation restricted to it, satisfies each axiom of ZF.

A class function $j: V \rightarrow M$ from the universe V of sets into an inner model M is an *elementary embedding* if for any set-theoretic formula $\varphi(v_1, v_2, \dots, v_n)$ and sets a_1, a_2, \dots, a_n ,

$$\begin{aligned} V \models \varphi[a_1, a_2, \dots, a_n] &\text{ exactly when} \\ M \models \varphi[j(a_1), j(a_2), \dots, j(a_n)]. \end{aligned}$$

(This suggests the general notion of elementary embedding in model theory; the notion cannot be formalized for V in ZFC, but sufficient schematic approximations can. Below, elementary embeddings are assumed not to be the identity function.) L is the paradigmatic inner model. Appealing to its definability Scott established: *If there is a measurable cardinal, then $V \neq L$.* Large cardinal

hypotheses thus assumed a new significance through a new proof construction, as a means for maximizing possibilities away from Gödel's delimitative universe. The ultrapower construction provided one direction and H. Jerome Keisler soon provided the other of a new characterization that established a central structural role for measurable cardinals: *There is an elementary embedding $j: V \rightarrow M$ for some inner model M exactly when there is a measurable cardinal.* Through model-theoretic methods set theory was brought to the point of entertaining elementary embeddings into well-founded models, soon to be transfigured by a new method for getting well-founded *extensions* of well-founded models.

FORCING

In 1963 Paul Cohen established the independence of the Axiom of Choice from ZF and the independence of the Continuum Hypothesis from ZFC. That is, complementing Gödel's relative consistency results with L Cohen established that $\text{Con}(\text{ZF})$ implies $\text{Con}(\text{ZF} + \text{the negation of AC})$ and that $\text{Con}(\text{ZFC})$ implies $\text{Con}(\text{ZFC} + \text{the negation of CH})$. These results delimited ZF and ZFC in terms of the two fundamental issues at the beginnings of set theory. But beyond that, Cohen's proofs were soon to flow into method, becoming the inaugural examples of *forcing*, a remarkably general and flexible method for extending models of set theory. Forcing has strong intuitive underpinnings and reinforces the notion of set as given by the first-order ZF axioms with conspicuous uses of Replacement and Foundation. If Gödel's construction of L had launched set theory as a distinctive field of mathematics, then Cohen's method of forcing began its transformation into a modern, sophisticated one. Cohen's particular achievement lies in devising a concrete procedure for extending well-founded models of set theory in a minimal fashion to well-founded models of set theory with new properties but without altering the ordinals. Set theory had undergone a sea-change, and beyond simply how the subject was enriched, it is difficult to convey the strangeness of it.

Cohen's approach was to start with a model M of ZF and adjoin a set G , one that would exhibit some desired new property. He realized that this had to be done in a minimal fashion in order that the resulting structure also model ZF, and so imposed restrictive conditions on both M and G . He took M to be a countable standard model, that is a countable transitive set that together with the membership relation restricted to it is a model of ZF. (The existence of such a model is an avoidable assumption in formal relative consistency proofs via forcing.)

The ordinals of M would then coincide with the predecessors of some ordinal ρ , and M would be the cumulative hierarchy $M = \bigcup_{\alpha < \rho} (V_\alpha \cap M)$.

Cohen then established a system of terms to denote members of the new model, finding it convenient to use a ramified language: For each $x \in M$ let \dot{x} be a corresponding constant; let \dot{G} be a new constant; and for each $\alpha < \rho$ introduce quantifiers \forall_α and \exists_α . Then develop a hierarchy of terms as follows: $M_0 = \{\dot{G}\}$, and for limit ordinals $\delta < \rho$, $M_\delta = \bigcup_{\alpha < \delta} M_\alpha$. At the successor stage, let $M_{\alpha+1}$ be the collection of terms \dot{x} for $x \in V_\alpha \cap M$ and "abstraction" terms corresponding to formulas allowing parameters from M_α and quantifiers \forall_α and \exists_α . It is crucial that this ramified language with abstraction terms is entirely formalizable in M , through a systematic coding of symbols. Once a set G is provided from the outside, a model $M[G] = \bigcup_{\alpha < \rho} M_\alpha[G]$ would be determined by the terms, where each \dot{x} is to be interpreted by x for $x \in M$ and \dot{G} is to be interpreted by G , so that: $M_0[G] = \{G\}$; for limit ordinals $\delta < \rho$, $M_\delta[G] = \bigcup_{\alpha < \delta} M_\alpha[G]$; and $M_{\alpha+1}[G]$ consists of the sets in $V_\alpha \cap M$ together with sets interpreting the abstraction terms as the corresponding definable subsets of $M_\alpha[G]$ with \forall_α and \exists_α ranging over this domain.

But what properties can be imposed on G to ensure that $M[G]$ be a model of ZF? Cohen's key idea was to tie G closely to M through a system of sets in M called *conditions* that would approximate G . While G may not be a member of M , G is to be a subset of some $Y \in M$ (with $Y = \omega$ a basic case), and these conditions would "force" some assertions about the eventual $M[G]$ that is, by deciding some of the membership questions whether $x \in G$ or not for $x \in Y$. The assertions are to be just those expressible in the ramified language, and Cohen developed a corresponding *forcing relation* $p \Vdash \phi$, " p forces ϕ ", between conditions p and formulas ϕ , a relation with properties reflecting his approximation idea. For example, if $p \Vdash \phi$ and $p \Vdash \psi$, then $p \Vdash \phi \& \psi$. The conditions are ordered according to the constraints they impose on the eventual G , so that if $p \Vdash \phi$, and q is a stronger condition, then $q \Vdash \phi$. Scott made an important suggestion simplifying the definition for negation: $p \Vdash \neg \phi$ if for no stronger condition q does $q \Vdash \phi$. It was crucial to Cohen's approach that the forcing relation, like the ramified language, be definable in M .

The final ingredient is that the whole scaffolding is given life by incorporating a certain kind of set G . Stepping out of M and making the only use of its countability, Cohen enumerated the formulas of the ramified language in a countable sequence (shades of Skolem's

Paradox!) and required that G be completely determined by a countable sequence of stronger and stronger conditions p_0, p_1, p_2, \dots such that for every formula φ of the ramified language exactly one of φ or $\neg \varphi$ is forced by some p_n . Such a G is called a *generic* set. Cohen was able to show that the resulting $M[G]$ does indeed satisfy the axioms of ZF: Every assertion about $M[G]$ is already forced by some condition; the forcing relation is definable in M ; and so the ZF axioms, holding in M , mostly crucially Power Set and Replacement, can be applied to derive corresponding forcing assertions about ZF axioms holding in $M[G]$.

The extent and breadth of the expansion of set theory described henceforth far overshadows all that has been described before, both in terms of the numbers of people involved and the results established. With clear intimations of a new and concrete way of building models, set theorists rushed in and with forcing were soon establishing a cornucopia of relative consistency results, truths in a wider sense, some illuminating classical problems of mathematics. Many different forcings were constructed for adding new real numbers and iterated forcing techniques were quickly broached.

Robert Solovay played a prominent role in the forging of forcing as a general method, and he above all in this period raised the level of sophistication of set theory across its breadth from forcing to large cardinals. Solovay proved a result already in 1964 remarkable for its sophistication: Suppose that κ is an inaccessible cardinal; then in an inner model of a forcing extension, κ becomes \aleph_1 , the least uncountable cardinal, every set of real numbers is Lebesgue measurable, and Dependent Choices (a substantial form of AC for bolstering measure) holds. This model offered important insights into the possibilities of measure and the limits imposed by AC. The inaccessible cardinal was thought for some time to be an artifact of the proof, when in 1979 Saharon Shelah finally complemented Solovay's result by showing that if every set of real numbers is Lebesgue measurable and Dependent Choices holds, then \aleph_1 (in V) is inaccessible in the constructible universe L .

Through the 1970s and into the 1980s the forcing method was honed with sophisticated iterated forcing techniques, techniques that established new, more contextualized relative consistency results in the self-generating mainstreams of set theory, *infinitary combinatorics* and *cardinal invariants of the continuum*. Donald Martin formulated an instrumental "axiom," *Martin's Axiom* (MA), in terms of forcing notions, an axiom that became convenient and focal for relative consistency

results. MA together with the failure of CH is relative consistent with ZFC via forcing, and MA directly implies many combinatorial statements in a way analogous to how CH had, and so relative consistency results can be established by drawing direct consequences from MA. A culmination in this direction was the work of Shelah in the 1980s on *proper forcing*, a wide class of forcing notions. Corresponding to MA in this context is the *Proper Forcing Axiom*, an axiom requiring large cardinals to establish its relative consistency. An important barrier that has resisted many efforts is that starting with a model of CH, many iterated forcing constructions have established the relative consistency of various propositions with the continuum being \aleph_2 , but corresponding relative consistencies with the continuum being at least \aleph_3 are not known. Can this be a limitation of forcing, or a delimitation imposed by ZFC?

LARGE CARDINALS AND INNER MODELS

A subtle connection quickly emerged, already in the 1960s and into the 1970s, between large cardinals and combinatorial propositions low in the cumulative hierarchy: Forcing showed just how relative the Cantorian notion of cardinality is, since one-to-one correspondence functions could be adjoined to models of set theory easily, often with little disturbance. In particular large cardinals, highly inaccessible from below, were found to satisfy substantial propositions even after they were "collapsed" by forcing to \aleph_1 or \aleph_2 , that is correspondence functions were adjoined to make the cardinal the first or second uncountable cardinals respectively. Conversely such propositions were found to entail large cardinal hypotheses in the clarity of an L -like inner model, sometimes the very same initial large cardinal hypothesis. Thus, in a subtle synthesis, hypotheses of length concerning the extent of the transfinite were correlated with hypotheses of width concerning the fullness of power sets low in the cumulative hierarchy, sometimes the arguments providing *equi-consistencies*. Solovay's Lebesgue measurability result from inaccessibility when complemented by Shelah's result became an equi-consistency, albeit a sophisticated one bringing together Cantor's two legacies, the investigation of definable sets of reals and the extension of number into the transfinite. Other "weak" large cardinals were formulated, sometimes in response to the need of a large cardinal concept to gauge a set-theoretic proposition via equi-consistency. The complementarity also encompassed "strong" large cardinal hypotheses formu-

lated in terms of elementary embeddings and later, new canonical inner models.

Large cardinal hypotheses stronger than measurability were charted out in the late 1960s, motivated not only by the heuristics of generalization but also by those of *reflection*. The direct reflection heuristic is that various properties attributable to the class of all ordinals, since its extent is uncharacterizable, should be attributable already to some cardinal. This heuristic was already at work in Zermelo's 1930 paper and extends the closure provided by Replacement. The more subtle reflection heuristic is that strong large cardinal hypotheses posit elementary embeddings $j: V \rightarrow M$, and the closer the target inner model M is to V , the stronger the properties that translate and can be reflected between. The *supercompact* cardinals were thus formulated by Solovay and William Reinhardt as global generalizations of measurable cardinals; stronger than these were the *n-huge* cardinals; and the stronger hypotheses still were formulated. There is an ultimate delimitation in this direction that has framed the possibilities: Kenneth Kunen established in ZFC that there can be no elementary embedding $j: V \rightarrow V$ of the universe into itself. ZFC rallied at last to force a veritable Götterdämmerung for large cardinals.

The theory of these strong hypotheses was developed particularly to investigate the possibilities for elementary embeddings. But what really intimated their potentialities were new forcing proofs, especially from supercompactness, that established the relative consistency of strong existence assertions low in the cumulative hierarchy, at the very least lending these assertions an initial plausibility. The possibility of new complementarity was then brought about through the development of *inner model theory*, the mostly sophisticated part of the theory of large cardinals.

Gödel's L was the first inner model, and Ronald Jensen dramatically transformed its investigation in the 1960s by refining the first-order definability and Skolem hull arguments to a "fine structure" analysis, extracting important combinatorial principles and establishing new relative consistencies. Inner models of measurability were soon developed, and their interactions and fine structure investigated, and these models would be paradigmatic for inner models of large cardinals: They exhibited in their crystalline clarity akin to algebraic closure the minimal consequences of the large cardinal hypothesis and the maximal structural regularity. In the 1970s, Jensen and Anthony Dodd developed the *core model* for measurability, and this would be paradigmatic for core models of large cardinals: These were inner models that did not

contain the large cardinal, but exhibited the maximal possibilities "up to" the cardinal. The ascent through the large cardinal hierarchy had begun, the inner and core models providing an abiding sense of structure for large cardinal hypotheses.

The development of core models, while quickly developing a life of its own, was initially triggered by work on the Singular Cardinals Problem. With the advent of forcing it had been quickly seen that ZFC imposed little control on the powers 2^κ of *regular* cardinals κ , successor or limit, since it became possible to extend a model of set theory by adjoining arbitrarily many subsets of such κ without adjoining any subsets of smaller cardinals. Thus Cantor's Continuum Problem and its generalization to regular cardinals were informed by a general manifestation of method. What about singular cardinals? Powers of singular cardinals seemed much less flexible with respect to forcing, and the *Singular Cardinals Problem* is the general problem of clarifying the possibilities for the function 2^κ for singular cardinals κ . Jensen, who found a seminal 1974 result of Jack Silver on powers of singular cardinals "shocking," was directly inspired by it to establish the *Covering Theorem* for L , easily the most important result of the 1970s in set theory. Very loosely speaking this theorem asserts that unless a surprisingly simple proximity criterion between V and L holds, a large cardinal transcendence over L ensues. It was efforts to extend this result that led to the core models. Through forcing and inner model analysis, results especially of Moti Gitik of the late 1980s established equi-consistency results for simple assertions about powers of singular cardinals and showed remarkable level-by-level connections with large cardinals that affirmed their central place in the investigation of the transfinite.

The extensive research through the 1970s and 1980s considerably strengthened the view that the emerging hierarchy of large cardinals provides *the* hierarchy of exhaustive principles against which all possible consistency strengths can be gauged, a kind of hierarchical completion of ZFC. First the various hypotheses, though historically contingent, form a *linear* hierarchy, one neatly delimited by Kunen's inconsistency result. Typically for two large cardinal hypotheses, below a cardinal satisfying one there are many cardinals satisfying the other, in a sense prescribed by the first. And second, a variety of strong propositions have been informatively bracketed in consistency strength between two large cardinal hypotheses: the stronger hypothesis implies that there is a forcing extension in which the proposition holds; and if the

proposition holds, there is an inner model satisfying the weaker hypothesis.

One of the great successes for large cardinals has to do with perhaps the most distinctive and intriguing development in modern set theory. Although the *determinacy of games* has roots as far back as a 1913 note of Zermelo, the concept of infinite games only began to be seriously explored in the 1960s when it was realized that it led to “regularity” properties for sets of real numbers like Lebesgue measurability.

With ω the set of natural numbers let ${}^\omega\omega$ denote the set of functions from ω to ω . For $A \subseteq {}^\omega\omega$, $G(A)$ denotes the following “infinite two-person game with perfect information”: There are two players, *I* and *II*. *I* initially chooses an $x(0) \in \omega$; then *II* chooses an $x(1) \in \omega$; then *I* chooses an $x(2) \in \omega$; then *II* chooses an $x(3) \in \omega$; and so forth:

$$\begin{array}{l} I : x(0) \quad x(2) \quad \dots \\ II: \quad x(1) \quad x(3) \quad \dots \end{array}$$

Each choice is a *move* of the game; each player before making each of his moves is privy to the sequence of previous moves (“perfect information”); and the players together specify an $x \in {}^\omega\omega$. *I* wins $G(A)$ if $x \in A$, and otherwise *II* wins. A *strategy* is a function from finite sequences of natural numbers to natural numbers that tells a player what move to make given the sequence of previous moves. A *winning strategy* is a strategy such that if a player plays according to it he always wins no matter what his opponent plays. A is *determined* if either *I* or *II* has a winning strategy in $G(A)$. The extent of the determinacy of games was investigated through hierarchies of definable sets of reals, and in 1962 the following sweeping axiom was proposed:

AXIOM OF DETERMINACY. Every $A \subseteq {}^\omega\omega$ is determined.

This axiom actually contradicts the Axiom of Choice, as one can get a counterexample A by “diagonalizing” through all strategies, and so the axiom was intended to hold at least in some inner model to establish regularity properties for sets of real numbers there. In the late 1960s initial connections were made between the Axiom of Determinacy and large cardinals by Solovay, who showed in ZF that the axiom implies that \aleph_1 is measurable, and by Martin, who showed in ZFC that if there is a measurable cardinal, then the analytic sets, the simplest significant sets of real numbers definable with quantifiers ranging over real numbers, are determined. Investigating further consequences of determinacy, a new

generation of descriptive set theorists soon established an elaborate web of connections in the unabashed pursuit of structure for its own sake. Determinacy hypotheses seemed to settle many questions about definable sets of reals and to provide new modes of argument, leading to an opaque realization of the old Cantorian initiatives concerning sets of real numbers and the transfinite with determinacy replacing well-ordering as the animating principle. By the late 1970s a more or less complete theory for the “projective” sets of real numbers was in place, and with this completion of a main project of descriptive set theory attention began to shift to questions of overall consistency.

The investigation of the Axiom of Determinacy spurred dramatic advances in the theory of large cardinals and affirmed their central role in gauging consistency strength. In the 1970s the strength of the methods made possible by the axiom led to speculation that either the axiom was orthogonal to large cardinals or would subsume them in a substantial way. However, large cardinal hypotheses, first near Kunen’s inconsistency and then around supercompactness, were shown to tame Determinacy. By looking at the workings of a proof, Hugh Woodin in 1984 formulated what is now known as a *Woodin cardinal*. Then Martin and John Steel showed that having more and more Woodin cardinals establishes the determinacy of more and more sets in the “projective hierarchy” of sets, sets of real numbers definable with quantifiers ranging over the real numbers. Finally Woodin established by 1992: *the existence of infinitely many Woodin cardinals is equi-consistent with the Axiom of Determinacy*. Woodin cardinals are weaker than supercompact cardinals, closer to measurable cardinals, and in subsequent developments the inner model theory was advanced to getting inner and core models of Woodin cardinals.

Woodin in the late 1990s built on the wealth of ideas surrounding Woodin cardinals and Determinacy and raising them to a higher level proposed a resolution of the Continuum Problem itself. This resolution features the use of arbitrarily many Woodin cardinals, the assimilation of new principles for sets of sets of real numbers, and an unresolved new conjecture about a new “logic” that would complete the picture. Thus structural ideas involving large cardinal hypotheses may circle back to effect an ultimate resolution of the original problem that stimulated the development of set theory.

What about the consistency of large cardinal hypotheses? As postulations for cardinals of properties of the class of all ordinals, they inherit substantial inaccessi-

bility properties from below, but even for large natural numbers given notationally, the meaning of a number is not conveyed by its dogged approach from below but by its mathematical postulation and the sense given it by proof and method. The inner model theory has fortified large cardinals up to Woodin cardinals by providing them with coherent inner models whose structure incisively exhibit their consistency. As for the hypotheses near Kunen's inconsistency, since that result was based on a combinatorial contingency, it could well be that a like inconsistency for a weaker hypothesis can be established. In any case these near-inconsistency hypotheses are less relevant, the forcing proofs applying them to get initial plausibilities having given way to more refined arguments from weaker hypotheses. Moreover the work of Woodin has shown that there is also quite a lot of structure near the Kunen inconsistency, analogous to the descriptive set theory of real numbers.

Stepping back to gaze at modern set theory, the thrust of mathematical research should deflate various possible metaphysical appropriations with an onrush of new models, hypotheses, and results. Shedding much of its foundational burden, set theory has become an intriguing field of mathematics where formalized versions of truth and consistency have become matters for manipulation as in algebra. As a study couched in well-foundedness ZFC together with the spectrum of large cardinals serves as a court of adjudication, in terms of relative consistency, for mathematical propositions that can be informatively contextualized in set theory by letting their variables range over the set-theoretic universe. Thus set theory is more of an open-ended framework for mathematics rather than an elucidating foundation. It is as a field of mathematics proceeding with its own internal questions and capable of contextualizing over a broad range that set theory has become an intriguing and highly distinctive subject.

Akihiro Kanamori (2005)

SEXISM

The term *sexism* denotes any system of beliefs, attitudes, practices, social norms, or institutional forms that functions to create or perpetuate invidious social distinctions among persons on the basis of their actual or presumed sex. This characterization of sexism reflects a widespread consensus among feminist theorists and queer theorists that the phenomenon cannot be understood simply in terms of the prejudices or ill-intentioned behavior of individuals, but rather must be seen as involving wide-ranging social structures, structures that can affect both the meanings and consequences of the actions of individuals, even if such actions are otherwise benign.

Marilyn Frye (1983) has explained, in just these terms, the inadequacy of a definition of sexism as any act or policy involving an “irrelevant or impertinent marking of the distinction between sexes.” She then bids us to consider an employer who refuses to hire a woman for a managerial position on the stated grounds that his employees would not accept the authority of a woman. We may suppose that the supervisor is right about his employees’ attitudes; thus the woman’s sex is, as things stand, relevant to her ability to do the managerial job. By this definition, then, the employer’s act of discrimination would not count as sexist, yet sexism is surely at work, somehow, in this situation.

The problem, Frye argues, is that the definition fails to take account of the ways in which preexisting social conditions can make sex relevant in situations where it need not be, and should not be. In this case, myriad factors had already conspired to create conditions in which the male employees would not be inclined to trust a woman’s judgment, or would not accept her possessing even limited authority over them. Such factors might include: 1) a history of explicit, *de jure* discrimination against women, limiting their participation in public life and their opportunities to assume authoritative social roles; 2) widespread belief (perhaps as a result of number one above) that women are incapable of carrying out the duties of a manager; 3) gender norms that would make it humiliating for men to submit to the authority of a woman. Against such a background, a woman’s sex becomes relevant to the question of whether she can do the job at hand, no matter what other relevant qualifications she possesses.

Another important point illustrated by this example is that sexism does not require bad intentions. In Frye’s case, we need not assume that the employer shares his workers’ prejudices. He may believe the woman to be otherwise qualified, and regret that circumstances make it unwise for him to hire her. Whether he should be criticized for accommodating the sexist views of his employees is certainly a reasonable question, but it is not the same as the question whether the hiring decision was sexist. The point of recognizing sexism is not to indict and punish individuals, but rather to identify and alter all the factors that contribute to the subordination of women, where it is acknowledged that many of these will involve well-entrenched and perfectly mundane social practices.

Richard Wasserstrom (1977) has made the same point, distinguishing what he calls institutional racism and sexism from overt and covert racism and sexism. In the latter two cases, laws or policies are designed with the

explicit intent of allocating unjustified burdens or unwarranted benefits to individuals on the basis of race or sex. In the overt cases, the categories of race and sex are explicitly mentioned, whereas in the covert cases, the categories are represented by surrogates. Jim Crow laws in the United States and the denial of the franchise to women in the United States prior to 1920 exemplify overt racism and sexism, respectively. The use of grandfather clauses after the U.S. Civil War (1861–1865) to disenfranchise formerly enslaved black men, and workplace safety rules that bar from certain jobs anyone capable of becoming pregnant exemplify covert racism and sexism.

Institutional racism and sexism, however, differ from both covert and overt forms in that there need be no intention on anyone’s part to produce a racist or sexist consequence. Wasserstrom recognizes two sub-forms. The first involves regulations or practices that, while apparently neutral, operate against a social reality already configured by racism or sexism, so that their effects are to maintain or reinforce an unjust social hierarchy. This may be the case with the practice of assigning children to schools on the basis of their neighborhoods—if there is *de facto* segregation in housing, then the assignment policy will lead to or sustain racial segregation of schools, even if no one intended that outcome. The second sub-form of institutional racism or sexism involves practices that embody—at a level not readily accessible to consciousness—racist or sexist concepts and presuppositions. Let us consider in this context the question, raised frequently by critics of feminism, whether it is sexist for a man to offer a seat to a woman on a bus.

It is certainly true that many men sincerely regard gestures of this sort as courteous and respectful, and are offended by the suggestion that the gestures denigrate women. Still, if one probes the larger meaning of these customs, it becomes clear that they are part of a system of conventions that symbolically express and prescribe women’s dependency upon and subordination to men. In the first place, there is no plausible moral or empirical rationale for making sex *per se* the criterion for the appropriateness of such a gesture. General moral considerations dictate that any able-bodied person—regardless of their sex—ought to offer a seat to anyone who is visibly incapacitated or subject to physical stress; a person on crutches, someone struggling with packages, or someone obviously exhausted, as might be the case for a woman in the late stages of pregnancy. But these conditions are not connected to sex. The suggestion that women must be accorded respect in virtue simply of their being female is simply peculiar.

There are obvious rationales for social conventions encoding such a stance toward the elderly: Age correlates with experience and wisdom and younger people are generally indebted in various ways to older people. But there is no estimable quality that correlates with femaleness *per se*. By contrast, the gestures and conventions we are considering make perfect sense in light of the prerequisites of a gender system that makes physical weakness normative for women (the “weaker sex”) and physical strength and control normative for men. Such gestures express the relationship that ought to hold between men and women. In a system of social organization in which men hold, or are assumed to hold, real power over women, conventional acts of faux deference by men to women (such as a man’s rising when a woman enters the room) function not as symbols of genuine respect, but rather as expressions of *noblesse oblige*.

Feminist theorists agree that the kinds of gender roles that exist in patriarchal societies are the raw material of sexism, but disagree about whether the elimination of sexism requires the complete dismantling of gender roles, or only their reform. Some feminist theorists argue that any way of attaching systematic social significance to biological sex will inevitably prove sexist. Theorists of this sort include so-called humanistic feminists, who hold that biological sex is a property accidental to, and thus morally irrelevant to one’s humanity (De Beauvoir 1973, Nussbaum 1999, Antony 1998), and dominance theorists, who hold that gender differences are constructed *ex post facto* to mask or rationalize preestablished power disparities (Haslanger 2000, MacKinnon 1987). All such theorists point out that gender roles function to enforce both sexual dimorphism (the demand that one be clearly identifiable and self-identified as either male or female), and compulsory heterosexism (the requirement that one’s erotic interest be focused exclusively on individuals of the opposite gender).

These restrictive social norms are not only deeply oppressive to transgendered and nonheterosexual people, but distorting and limiting for all members of a human society. Theorists who hold this position generally believe that a great deal of the content of gender roles is socially constructed—that there is no natural necessity linking the components of biological sex (morphology, endocrinology, and genetics) to the features of particular gender roles. But the issue of the naturalness of gender roles is in fact orthogonal to the question whether such roles should be socially enforced. Myopic people are biologically (and probably genetically) different from non-myopic individuals; nonetheless, we assign no social

significance to this difference, and in fact acknowledge a social obligation to mitigate the natural consequences of poor eyesight.

Other feminist theorists hold that there is nothing inherently wrong with the existence of gender roles, and that such roles could, in a different social context, be liberatory and beneficial for all. On this view, sexism is constituted by two things: a) the gratuitous attachment of undesirable qualities, such as physical weakness, to the feminine gender role; and b) the widespread devaluation of central elements of that role, such as emotional sensitivity. According to these theorists, sometimes called *gynocentric* or *difference* feminists, facts about the female role in biological reproduction have inherent social significance, and so there is no serious prospect for eliminating social roles erected on the basis of reproductive difference (Young 1985). Central, then, to a feminine gender role will be the social role of mothering. Because the individuals who have been the predominant occupiers of this role are women, and because women have historically lacked social power, the virtues necessary for the proper performance of this role (e.g., empathy, cooperativeness, imaginativeness, nurturance, and altruism) have been devalued.

To dismantle sexism, these feminine virtues must be recognized as being as important to morality as masculine virtues such as impartiality (Gilligan 1982) and greater social support must be provided those who fulfill such typically feminine roles as tending children, caring for the sick, and managing social relationships (Ruddick 1989). Closely allied with gynocentric feminists are *ecofeminists*, who think that women’s greater involvement with the bodily realities of birth, growth, and even death (in their roles as nurses and caregivers) create for women a more intimate relationship with the natural world than men have (Plumwood 1993). This, in turn, makes women more apt than men to strive for ways of life that are harmonious with nature, with nonhuman animals, and with other human beings. All these theorists agree that war and other forms of violence reflect the sexist devaluation of the feminine, and that a proper appreciation of feminine virtues is essential to producing peace.

This dispute within feminist theory about the nature of sexism has implications for social and legal policy. Gynocentric feminists charge that humanistic feminists are guilty of androcentrism—taking the male as the paradigm of the human. If laws and social institutions take no account of differences between men and women, then women will be forever socially and economically disadvantaged by policies and practices centered on male

needs, abilities, and interests. Humanistic feminists counter that they find the content of masculine gender roles just as objectionable as the content of feminine roles, and equally in need of elimination. The revalued gender roles envisioned by gynocentric feminists reflect a romanticized view of female experience, and threaten to legitimate a host of sexist stereotypes and prescriptions. Laws and policies should be based on parameters rationally related to the issue involved, parameters that will sometimes coincide with sex differences, but will more often not.

Feminist theorists have been increasingly concerned with understanding interactions among sexism and a host of other systems of oppressive social division, including racism, heterosexism, class oppression, ageism (invidious division on the basis of age), and ableism (invidious division on the basis of physical capacities), ethnocentrism, and jingoism. Critical legal theorist Kimberle Crenshaw has introduced the notion of intersectionality to capture the *sui generis* character of multidimensional oppression. Postmodern feminist theorists have appealed to this ever-increasing list of interacting parameters of identity to deconstruct categories such as sex and race, arguing that no one is simply or straightforwardly a woman or a black person, but that the self is essentially fragmented and fluid. However, they acknowledge the difficulty of making sense of oppression without appeal to such categories.

Louise M. Antony (2005)

SEXTUS EMPIRICUS

(third century CE)

Sextus Empiricus was almost certainly, as his name suggests, a doctor of the empiricist school, which flourished from the third century BCE until at least the third century CE. His dates are very uncertain, but he probably lived and worked, perhaps in Rome, sometime early in the third century CE. He is mentioned as a prominent skeptic in Diogenes Laertius's *Lives of the Philosophers* (DL) 9.116, written probably in the third century; but the men Diogenes names as his teacher and pupil, Herodotus of Tarsus and Saturninus, are even more obscure. He was certainly known as the authoritative source of skeptical argument a century later, when Saint Gregory of Nazianzus blamed him for the "vile and malignant disease" of arguing both sides of a question that was infecting the church. How original he was is unclear—it is hard to tell partly because our other sources for skepticism are so exiguous—but he seems to have been more of a compiler than an original thinker; and in any case it is to his preservation of a large body of skeptical argumentation, whatever its provenance, that his importance in the history of philosophy is due.

His best-known work is *Outlines of Pyrrhonism* (PH), a digest of the arguments and general strategy of that version of skepticism named for Pyrrho of Elis. The precise relationship between the position outlined by Sextus and that of Pyrrho is unclear—Sextus himself says that his philosophy is called "Pyrrhonism" because "he seems to have applied himself to skepticism more thoroughly and conspicuously than any of his predecessors" (PH 1.7). PH summarizes what Sextus presents at much greater length in another work that also survives, at least in part. This consists of the five surviving books generally

(if misleadingly) known as *Against the Professors* (M 7–11, subdivided as *Against the Logicians* (M 7–8), *Against the Physicists* (M 9–10), and *Against the Ethicists* (M 11). M 7–8 corresponds roughly to an expanded version of PH 2, while M 9–11 is summarized in PH 3. Whatever answered to the general treatment of skepticism in PH 1 is lost. The texts known as M 1–6 form a different treatise, written with a rather different aim, consisting of a series of essays directed against the practices (and practitioners) of six of the seven “liberal arts,” in order, grammar, rhetoric, arithmetic, geometry, astrology, and music. Sextus also tells us that he wrote medical texts as well, but these are lost.

Book 1 of PH presents a general account of skeptical practice. Sextus is careful to avoid any suggestion that what he is presenting is a doctrine, or anything else with uncomfortably Dogmatic overtones. “Dogmatist” was the general name given by skeptics to their opponents who held positive, or even negative, views (the term also functions as an umbrella term to describe theoretically minded, as opposed to empirical, doctors; and was probably borrowed from medical terminology). At the beginning of PH, Sextus presents skeptics as starting out from the same position as all other inquirers: They seek to assuage their disquiet by finding out the truth about things. But in any search there are three possible outcomes: one may (a) claim that one has found what one was looking for; (b) deny that it can be found, saying that it is inapprehensible; or (c) simply keep on searching. Option (a) is the position of the Dogmatists (Stoics, Epicureans, Platonists, and Aristotelians). Option (b) Sextus ascribes to the Academic skeptics, claiming (controversially) that they positively deny that things are apprehensible (in the sense of certainly knowable) as to their actual natures, while also claiming that certain positions, in regard to both factual and evaluative matters are “more plausible” than others (PH 1 236–241); and both of these positions are unacceptably Dogmatic from a Sextan perspective. Moreover, even though both schools report that *epochē* (suspension of judgment) regarding things that are naturally nonevident is the natural conclusion of the inquiry, the Academics present this as a goal, and as a good thing, whereas the Pyrrhonist has no attitude to it at all—it is simply something that happens, although it seems to bring tranquility (the acquisition of which was the initial object of the search) in its train (PH 1.21–30). The Pyrrhonist follows option (c), and keeps on inquiring, following the appearances, but suspending judgment about what, if anything, might lie behind them (PH 1.13–24).

Sextus is acutely aware of the dangers of incoherence involved in this presentation of a life without commitment—he cannot consistently *recommend* it (since that would involve supposing it to be objectively good, or at least choiceworthy); and he cannot claim that, as a matter of fact, following it will have the desired therapeutic effect of removing anxiety. But he can (undogmatically) report his own experiences; it seems to him that this is how things have gone. Moreover, he is moved (so he tells us) by benevolence: Seeing the Dogmatists suffering from their vain pretensions to knowledge, he seeks to cure them (PH 3.280–281), not because he positively affirms that it is good to do so, but simply because he finds himself so moved. In the same vein, skeptics adhere (undogmatically) to “a quadripartite practice of ordinary life,” since “we cannot remain wholly inactive”: they follow “the guidance of nature, the constraint of the affections, the tradition of laws and customs, and the instruction of the arts” (PH 1.23). The skeptic has a “criterion of action”—the appearances—but no “criterion of truth” (PH 2.13–79). Sextus thus shows himself sensitive to the sort of objection made famous by David Hume, but anticipated in the Greek tradition, that skepticism is fatal.

PH 1.31–163 presents a version of the Ten Modes of Aenesidemus, but in a manner that betrays the later influence of Agrippa. The Modes are collections of considerations designed to (or rather, which have been found to) induce *epochē* on all nonphenomenal matters (the causal language is important: there can be no inference as such for the Pyrrhonist). They consist in the collection of “oppositions”—Sextus describes skepticism as “a capacity for oppositions”: PH 1.8—cases where (apparently) x appears F to y (or in circumstances C), but not- F to z (or in circumstances C^*); since there can be no non-question-begging way of deciding on the superiority of any one of the opposed appearances over any other (that is, we have no criterion) “we are moved to suspend judgment” (PH 1.78; cf. 1.89, 99, 117). The skeptic will adduce considerations on both sides of any question to promote “equipoise of argument” (PH 1.8, 190), not in order to support or undermine one side or the other. If you claim p , skeptics will adduce reasons why not- p , not because they believe them *in propria persona*, but simply because their benevolence compels them to. All skeptical argument is dialectical. Thus when Sextus produces arguments against proof (PH 2.134–192), he does so not because he *believes*, inconsistently, in the capacity of proof, as the Dogmatists allege (PH 2.185–186); rather it is the Dogmatists who, insofar as they believe the canons of rational argument, must find those canons undermined from within. The skeptic has no beliefs about them

at all (PH 2.187–192). And it is in this manner that Sextus deploys the vast bulk of his argumentation in PH 2–3 and M 7–11, for and against particular philosophical and scientific positions.

In a similar vein, Sextus discusses the “skeptical slogans,” such as “no more [so than not so],” *ouden mallon* (PH 1.188–191). The phrase *ouden mallon* had been used by earlier philosophers (including Democritus, Plato, Protagoras, and Pyrrho), but to signal, non-skeptically, that some things really *were* no more *F* than not-*F*. For the skeptic, it functions simply as a marker of a refusal to say, one way or another. Equally, when skeptics say “I determine nothing,” or “all things are undetermined” (PH 1.197–199), they do not assert that nothing is determinable; these are merely expressions of how things seem. Indeed, the skeptical slogans apply to themselves: skeptics determine nothing, not even that they determine nothing (PH 1.206–209); here again they can avoid the charge of “negative Dogmatism” (option (b) above) they level at the Academics.

At PH 1.210–241, Sextus seeks to distinguish Pyrrhonism from other superficially similar philosophies by stressing the fact that all of them slide into Dogmatism. Thus Pyrrhonism is not relativism, at least if that positively affirms that everything is relative; the Pyrrhonist appeals to the relativity of appearances, but draws no ontological conclusion therefrom. Curiously, Sextus even distinguishes his practice from that of the empiricist doctors. The latter follow the appearances; and make use of the type of sign (“commemorative”) that Sextus allows (PH 2.100–102), in which something evident is a sign of something else that is only temporarily nonevident, that is, whose existence can be confirmed by further investigation, as when smoke is a sign of (concealed) fire. (Sextus

rejects “indicative signs,” whereby Dogmatists seek to infer to the hidden internal structures of things on the basis of evident phenomena, on the grounds that there can be no noncontroversial inference of such a kind: PH 2.104–133; M 8 199–300). But they also developed a complex epistemology of reasonable expectation, based upon personal observation, reportage, and argument form analogy. And for Sextus, this strays too far toward a Dogmatic supposition that certain outcomes really are more likely than others. For this reason, he prefers the methodic school of medicine as a model, since this school also makes no affirmations, and simply follows the “quadripartite practice of ordinary life” (PH 236–141). In this vein, in M 1–6, Sextus allows that it is fine to practice some skill, as long as one does so undogmatically, that is without commitment to any supposed deep truths that the skill relies upon. This is the sense in which the skeptic may follow “the instruction of the arts,” and how Sextus may consistently be a (type of) doctor.
